In volume 1 particle 2 in. in diameter equals 8 particles 1 in. in diameter. In surface area 1 particle 2 in. in diameter contains one-half the surface area as the 8 particles 1 in. in diameter. Theoretically it would require but one-half the amount of mortar to cover the 2-in. particle as it would to cover an equal volume of 1-in. particles. In practice this is not quite true because of the voids in the volumes of smaller particles, and also because the particles are not perfect spheres.

Mortar Required

By actual practice and a measurement of densities of a mass of sand and gravel it is absolutely established that the volume of 1-in. particles cited in the above case will require 1 1/2 times more mortar than the volume of 2-in.

For a comparison: determined by actual measurement:—

1 cu. ft. 1 1/2-in. gravel has 1.15 times the surface or contact area of 1 cu. ft. 2 in.

1 cu. ft. 1-in. gravel has 1.3 times the surface or contact area of 1 cu. ft. 2 in.

1 cu. ft. 3/4-in. gravel has 1.75 times the surface or contact area of 1 cu. ft. 2 in.

1 cu. ft. 1/2-in. gravel has 2.00 times the surface or contact area of 1 cu. ft. 2 in.

One reason for the excess of mortar required is plainly seen. One reason for the more cement required is established. The advantage gained by using the largest aggregate possible for reinforced concrete work is very evident. You have less surface contact, more bond adhesion, and stronger concrete.

The arguments brought against the use of the larger aggregates will be: honeycombing and pocketing, can't be done. The objection can be dismissed on the ground that in intelligently mixed and placed concrete, pocketing and honeycombing do not occur.

Two-inch aggregates can be used in 12-in. columns and 8-in. beam, the large gravel is merely displaced by the finer gravel and mortar, and when properly agitated will always flow into place. What do you care whether you have 2-in. aggregate in the core of a 12-in. hooped column or whether the finer material flows to the outside to act as a protective coating? Concretes richest in cement are least permeable. Measure the permeability of neat cement. Measure the permeability of 1 to 1 mortar. Measure the permeability of 1 to 2 mortar. The 1 to 2 mortar is about 100 per cent. more impermeable than the neat cement and about 50 per cent. more impermeable than the 1 to 1 mortar.

Permeability of Mortar

Measure the permeability of neat cement, of 1-1-1 concrete, and of 1-2-5 concrete. The 1-2-5 concrete is 100 per cent. more impermeable than the neat cement and about 40 per cent. more impermeable than the 1-1-1 concrete. The permeability of concrete is much influenced by grading of aggregate, particularly the sand. Using the same gravel and sand a 1-2-7 concrete is more impermeable than a 1-2-4, and this can be demonstrated, even with a poorly graded and fine sand.

In considering mortar—mortar to be permeable should contain a large percentage of fine sand, sand below No. 50 and nothing above No. 20. A coarse sand mortar is not nearly so impermeable as a fine sand mortar. Crushing gravel does not add to the strength of the concrete. Crushing merely increases the voidage due to the angularity of particles. Tests in crushed gravel 1 1/2 in. to 1/4 in. showed an increase of voidage for 35 per cent. natural material to 42 per cent. for crushed.

Graded crushed stone weighs less than graded natural gravel, the specific gravity being the same. Why? More voids. The particles of crushed stone are more nearly cubical than the gravel—more surface area (more contact area)—more voids.

Crushed limestone 1 1/4-in. to 1/20-in. voids 37 per cent. weight 98 lbs. per cu. ft.

Crushed granite 1 1/4-in. to 1/20-in. voids 41 per cent. weight 95.3 lbs. per cu. ft.

Screened gravel 1 1/4-in. to 1/10-in. voids 33 per cent. weight 102.4 lbs. per cu. ft.

Crushed limestone 1-in. to 1/4-in. voids 45 per cent. weight 85 lbs. per cu. ft.

Adhesion

A roughened and pitted gravel has the same adhesion for cement as that of crushed stone. Some river gravels on account of the smoothness, particularly quartsite pebbles, which are not only smooth, but hard to wash free of slimy accumulation, are not as good as crushed stone of the same hardness. The advantage of using gravel over broken stone is that gravel concrete works smoother (flows easier) and is more dense.

The writer would suggest that in analyzing sand for concrete purposes, sieves of 4 mesh, 14 mesh and 40 mesh be used, 100 per cent. to pass No. 4, not more than 70 per cent. to pass No. 14, not more than 30 per cent. to pass No. 40; this would assure a grading having enough sizes present to give an excellent mortar.

The Mainland Engineering Company, Limited, has been incorporated with head office in Vancouver and a capital of $50,000.

Gothic Church Work in Toronto

By Walter J. Allen, R.S.A.

Among the many and varied branches of wood work practised in this country none have suffered from an ignorance of its technique as has Gothic work.

One would have thought that a craft which has been eulogized for ages by all sorts and conditions of men—antiquaries, historians, architects, philosophers, scientists, travellers, etc—would have reached, in some sense, the exalted plane it rightly occupies in all civilized countries of the world.

Our neighbors across the line have long gained the pseudonym of "globe-trotters"; but the result of this "trotting" around the ancient cathedral churches of the Continent and Britain is reflected in some of the fairly magnificent churches of the United States—notably, perhaps, in the cathedral church of St. John, New York.

There are not wanting signs that Canada is slowly awakening to the peculiar richness and beauty of the true Gothic style. This is shown by the accompanying illustration, which, though small, sufficiently conveys the idea referred to. It is known as a "reredos," and was constructed by L. Rawlinson, Limited, for St. Simon's Church, Toronto. It is in the "Decorated Style" (or 13th-14th Century work). The three subject panels are surmounted by pierced canopy work, which finishes with a cap mould, the chief member of which is pierced enrichment, and finally the cresting, also pierced, and carries the dedicatory "Sanctus."

It is often asked, "Why do you pierce the tracery?" "Do you always cut it through?" etc. The answer is: All the finest examples of medieval work are so treated; the reason being that the "hallowed twilight"

Fig. 1 Reredos, St. Simon's Church, Toronto. A beautiful example of church woodwork

prevailing in the interiors of most of the old cathedrals and churches necessitated such treatment, if the richness of line and beauty of contour were not to be lost in the sacred gloom. In any case, however, whether interiors are dim or coldly light, the beauty of the work is much enhanced by a free use of the "open work" wherever possible. This will be especially noticeable in the general effect.

Exquisite examples of this pierced, or open, work in wood and stone were to be seen in the never-to-be-forgotten cathedral churches of Louvain, Lille, Rheims, etc. There are, of course, other fine examples still extant, some of which show the advantage of this particular treatment in other directions—as, for instance, the magnificent reredos, forty-six feet high, built in front of an equally magnificent stained glass window, each lending to the other a charm more easily imagined than described. This open worked reredos is in English oak, and cost £1,600. It is in St. Alban's Cathedral, Hertford.

Fig. 2 shows one of the two "wings," or sides, to the reredos shown in Fig. 1. These connect the reredos with the north and south walls, respectively. They are necessarily less elaborate than the centre

Fig. 2.—Side view of one wing of Reredos.

piece, or reredos proper, yet are in strict harmony therewith. The angels carry forward the idea expressed in the centre panel, Gloria in Excelsis.

This and a few other examples were wholly executed in Toronto.

The Sovereign Lime Company, Limited, has been incorporated, with a capital stock of $50,000, to carry on business as manufacturers of and dealers in lime, terra-cotta, brick, cement, mortar, concrete, asphalt, marl, tiles, drain and sewer pipes, stone and artificial stone, etc The head office of the company is in Montreal.

A Mixer for the Small Contractor

The London Concrete Machinery Company, Limited, London, Ont., have brought out the "Handy Mixer" suitable for the brick contractor, the plastering contractor, or for the smaller jobs in concrete work. It is claimed that in any job requiring less than 40 cubic yards of material per day this kind of mixer will prove an economy. There is no need of hauling a large mixer around for these small jobs,

while at the same time the expensive hand mixing method is done away with. The low cost of moving and operation make this mixer a valuable part of the equipment of all small jobs. The mix turned out by this machine is claimed to be equal to that of the large-size machines and, of course, vastly superior to hand work. One man can mix as much mortar with the "Handy" mixer as four men can by hand. In addition, it is claimed that around 25 per cent. of the lime or cement is saved. The illustration herewith shows a side view. The machine is operated by a 2 h. p. gasoline engine.

The Turbine Equipment Co. recently secured a contract from the Imperial Oil Company, Limited, for their new refinery at Montreal, for ten De Laval steam turbine-driven centrifugal pumps; also a contract from the Standard Chemical, Iron and Lumber Company for a one and a half million gallon De Laval motor-driven centrifugal pump.

There are now employed a number of processes whereby wood can be so altered in character that it becomes almost fire-proof, and is no longer liable to dry-rot or any of the disintegrations that come under the head of decay.

Under what is probably the best method, the wood, after having its sap extracted by air-suction in a closed vessel, is charged with a solution of metallic salts, the entire treatment occupying about four hours. It is said that green wood thus treated neither shrinks nor warps, thus obviating the seasoning generally necessary, and that soft woods become so hardened that they can be utilized for purposes for which they were quite unsuited in their original condition, and become almost incombustible and capable of receiving a high polish.

Barn Building Catalogue

Beatty Brothers, Limited, Fergus, Ont., are distributing a very attractive catalogue, called Book No. 26, covering barn construction and equipment. The book is splendidly illustrated with barns (exterior and interior) and various equipment as installed at many points in Canada by this company, and including such well-known names as Colonel Robertson, Williamstown, Ont.; Gordon Gooderham, Clarkson, Ont.; William Innes, Headingly, Man.; C. P. R. barn, Strath-

Col. Robertson's barn at Williamstown.

more, Alta.; Ottawa Dairy Company, Ottawa, Ont.; Robert Kelly, Vancouver, B.C.; James Dunsmuir, Victoria, B.C.; and many others. The illustration shows the fine barn recently erected and equipped by Beatty Brothers for Colonel Robertson.

Montreal's Asphalt Contracts

Last year the city of Montreal had considerable trouble over its supply of asphalt; legal proceedings followed the award of contracts, and for a time the city was tied up in the matter of completing its road programme. It was expected that this year the bids would be on a higher scale, and when the tenders for about 6,000 tons were opened it was found that about $5 a ton above last year's quotations was asked. The tenders received were: Warner-Quinlan Company, $19.33 per ton; Elder Ebano, $21.98, delivered at the north end yards, $23.23 delivered at the eastern yards, and $22.43 delivered at the Grand Trunk station; United States Asphalt Refining Company, $22.73; Sicily Asphalt, $26.40 for the Trinidad grade, and $32.40 for the Bermuda grade. The Board of Control referred the bids to the engineers' and law departments, and also asked that the samples be analyzed. The Imperial Oil Company wrote the Controllers asking that the city buy only quantities needed for immediate use, as the company intended to complete in August next a large asphalt refining plant at Pointe-aux-Trembles, and would then be in a position to supply the city.

Famous Picture Ads.

Word has just come from New York, which would indicate that a decided compliment has been paid to the Dunlop Tire & Rubber Goods Co. A large agency who keep a portfolio of the world's best advertising matter gathered together from every part of the map include in that portfolio the Dunlop "Famous Picture" series which appeared in Canadian newspapers last September. The "Famous Pictures" were the first ads. of the type ever run in America, or any other part of the world so far as can be traced, and that is probably the reason why the agency in question selected the series for their portfolio, as their big endeavor is to get new treatment on any subject or, in other words, originality all along the line.

Grouting at 700 lbs. Pressure

Grouting is now an established method of stopping flows of water in shafts, adits, and drifts. A mixture of cement and water, say a bag of cement to three 12-qt. pails of water, with sometimes a little sand, is forced by a grout-machine into holes drilled in the rock, the pressure being furnished by compressed air. Pressure of 100 to 200 lb. above the hydrostatic head is used in difficult shaft problems. The Nova Scotia Steel & Coal Co., in its iron mine at Bell Island, Newfoundland, where the mine workings are several miles out under the ocean, has a grout-car run on wheels that can force grout into rock at pressures as high as 700 lb. per square inch. By use of this grout-car the workings, although under the Atlantic ocean, are kept fairly free from large flows of water.

Fireless Steam Engine

A fireless steam locomotive is used for switching cars and tie trams at an Ohio creosoting plant. The locomotive is of a type which was developed in Europe some years ago and is used around distillation plants, where cinders and live ashes would constitute a fire danger. This locomotive operates by steam, the boiler being charged about seven times every twenty-four hours at the main boiler, at 150 lb. pressure. The maintenance cost of this type of switching engine is very low, and its use is said to be very satisfactory in a treating-plant yard. Its tractive power is fully equal to that of the usual type, and although it weighs only 22 tons it has pulled as many as twelve loaded gondola cars at a time. Perhaps there are construction contracts on which a locomotive of this type would be an economy.

Hamilton Gets Another Factory

The Ontario Yarn Co., Markham, have leased a building on Stuart Street, West, Hamilton, for a branch factory to manufacture knitting and hosiery yarns. About 25 or 30 hands will be employed and the plant will run 24 hours per day. Carding, spinning and winding machinery is being installed now and they expect to start operations by the first part of April.

Mr. H. P. Borden, Member of Commission

Mr. H. P. Borden, C. E., has been appointed a member of the Government commission which has charge of the construction of the new Quebec Bridge. This appointment is to fill the vacancy left by Mr. C. C. Schneider, of Philadelphia, deceased. Mr. Borden is well-known to the engineering profession, as he has been connected with the board since its inception, the last few years as assistant to the chief engineer.

The Canadian Facts Publishing Company, 588 Huron Street, Toronto, have just issued their 1916 edition of "Five Thousand Facts About Canada," compiled by Mr. Frank Yeigh, of Toronto.

Street Railway Track Construction

Development of Modern Methods of Laying Car Tracks—Concrete Base the Only Permanent Form

By R. Keith Compton*

Importance of Construction.—One of the most difficult problems which a municipal engineer faces in street improvement of today is the premanency of the street railway track construction. On this point hinges the durability and integrity of that portion of the pavement immediately in the railway area and adjacent thereto. Even in outlying suburban sections, pavements on streets where railway tracks exist are more difficult to construct and maintain than on streets where no tracks exist. The situation is intensified when similar streets are to be improved in heavy traffic sections of busy cities.

Early History.—The speaker takes the liberty of introducing into this subject his experience in the City of Baltimore, where this matter has been given most careful attention, both by the municipal authorities and the street railway officials. In collecting data on this subject from the principal cities of this country we find that other cities have passed through similar experiences. Some fifteen years ago it was the practice of street railway companies to lay the ties directly on the original earth foundation of the street, tamping up with whatever local material was convenient. Consequently track structures had absolutely no stability other than that given by the natural earth foundation existing in the street, so that within a few months after the street was improved and opened to traffic the rails would vibrate under the movement of cars and heavy trucks, with the result that cracks would develop in the paving adjacent to and for several feet on either side of the rails, causing rapid disintegration of the paving, particularly in the case of sheet asphalt. If the pavement were of stone or vitrified block, cracks would develop and the paving blocks would soon begin to "work" and loosen up. Within twelve months the paving in the railway area would be in such condition as to seriously impair the usefulness of the street. This disintegration did not confine itself to the railway area, but would gradually encroach upon the city area.

The next development in this construction was the installation of gravel ballast. This was somewhat of an improvement over the original construction, the only difference being that the development of cracks and disintegration was somewhat postponed. Gravel, being round and smooth, would shift under the strain of passing traffic, with results most damaging to the paving.

The crushed stone ballast was then used. On suburban streets with light car and vehicular traffic this was a decided improvement, and in some instances the results obtained, both as to track construction and maintenance of paving, were most desirable. Care, however, had to be taken by the track gangs to see that most careful tamping was done. The rock ballast construction, however, in heavy traffic downtown streets, did not give the results desired, so that in the past few years many cities have been installing a concrete slab, from 6 to 8 ins. in depth, under the ties, then brought up and completely enveloping the ties in concrete, and the concrete foundation for the paving installed on top of this.

Right here it may be well to note the following list of cities which have used or are using concrete as a foundation for track construction, in whole or in part. Most municipalities do not use it exclusively, but use concrete in the heavy traffic sections, and rock ballast in the suburban sections where car and vehicular traffic is light, or where the paving of streets may not be regarded as permanent on account of the surrounding property being undeveloped. This information was obtained in 1913 and 1914 through correspondence with municipal officials in the respective cities. These cities are as follows: New Orleans, La., Chicago, Ill., Buffalo, N. Y., St. Louis, Mo., Norfolk, Va., Boston, Mass., Detroit, Mich., New York (Brooklyn), Cleveland, O., Nashville, Tenn., Memphis, Tenn., Springfield, Mo., Birmingham, Ala., Dayton, O., Cincinnati, O., Baltimore, Md.

It is a fact that traction engineers as a rule object to concrete under the ties, claiming three distinct disadvantages:

Objections of Traction Officials.—First, that concrete under the ties makes the track construction entirely too rigid, and that rock ballast gives equally good results and overcomes this rigidity in that it allows a certain amount of resiliency, and that such resiliency is necessary, otherwise undue wear will take place on the rails from passing cars, and that rigid track construction is hard on the equipment.

Second, that in case of reconstruction the railway company is put to an unnecessary expense removing the concrete so as to replace defective or disintegrated ties with new ones.

Statistics show that there is no real ground for the first objection, and even if there were, this can be overcome by keeping the concerte base an inch or so low and bedding the ties in a thin bed of loamy sand on top of the concrete slab. Care should be taken, however, to bring the concrete up on the ends of the ties so as to confine the sand and prevent its shifting.

Replacing Ties

The second objection can be overruled by the fact that in replacing worn-out or disintegrated ties, the railway company does not have to remove any more concrete than it would otherwise remove were the pavement only on a concrete foundation of the usual thickness, as will be hereafter shown by the method of construction followed by the City of Baltimore. Furthermore, statistics compiled by the Board of Supervising Engineers in the City of Chicago, who have been giving this matter most thorough study for the past eight years, show that sound yellow pine ties, thoroughly embedded in concrete, are almost indestructible.

Another and third objection made by the traction officials is that the car lines have to be diverted, either by means of laying a third and temporary track on the street to be improved, or if the street is so narrow as to prohibit this, there has to be an entire re-routing of the cars, causing by either method serious inconvenience to the public and disorganization of the car company's traffic schedule. This claim can also be overruled by a method which the speaker will outline to you later, as followed by the City of Baltimore.

The experience of all municipal engineers along this line has probably been the same.

Baltimore Work.—Owing to the flat refusal of the traction authorities to install permanent construction, many of us have had to resort to legislative bodies for relief. In the beginning of the year 1914 the situation in the City of Baltimore was thoroughly studied, both by the municipal engineers and the traction officials, with the result that the State Legislature of Maryland was appealed to by the muni-

* Chairman and Consulting Engineer, Paving Commission, Baltimore, before American Good Roads Congress, Pittsburgh.

cipality and a law was passed putting the character of foundation under the ties of the several street railway companies and steam railroads under the jurisdiction of the Paving Commission, with power to decide whether such foundation should be of plain ballast or concrete. The commission decided that in heavy traffic downtown streets concrete construction, 6 ins. thick, under and around the ties, was necessary, but that in the outlying suburban section where the traffic was light and street development more or less of an uncertainty, awaiting property development, rock ballast could be used.

The traction officials were informed that they could install the ties immediately on top of the concrete or install a cushion between the top of the concrete and the bottom of the ties. They chose the former.

It may be interesting to note here that in the downtown business section of Baltimore the streets are exceedingly narrow, not over 40 ft. in width between curbs, and there is no room for a temporary third track. Furthermore, the gauge is of odd dimension, namely 5 ft. 4½ ins., so that the track area takes up more space than in most cities. It was also impossible, owing to congestion, to divert the cars to other streets. In order, therefore, to meet this, the third objection of the traction officials, it became necessary to install the concrete without interruption to car traffic. It was at first thought that this could be done by blocking up the tracks an inch or so above the exact grade, installing the concrete, allowing it to set and lowering the tracks to the proper and exact grade. The conclusion was reached, however, that this would not only be very expensive, but hardly feasible, so that it was then determined to pursue the penetration method. This was done by bringing the tracks to the exact grade and ballasting with crushed stone from 1½ to 2½ ins. in size, free of dust and small particles, and tamping the same thoroughly as in ballasting ordinary track, care being taken to thoroughly tamp the ballast and make the same carry the strain of passing cars, then applying a thin cement grout.

In improving streets containing railway tracks the forces of the railway company and that of the paving contractor have to work in conjunction. The railway area is first graded out to the subgrade of the paving by the paving contractor. The railway company then takes charge and grades out to a point 6 ins. below the bottom of the ties. New rails and ties are then installed where necessary, together with any new special work. The ballast, of the size and depth previously noted, is then placed and thoroughly tamped under the ties and up to a point 2 ins. above the bottom of the ties, the rails brought to the proper grade and line, and when the entire construction is "tight" the penetration begins.

Grouting Mixture

The grouting mixture is composed of 1 part cement to 2 parts sand, and is about the consistency of thin cream. The operation is readily done without interruption to car traffic by the use of a small continuous mixer (known as the Coltrin mixer) placed just outside of and parallel with the railway tracks, with a flexible chute, in two sections, to convey the grout from the mixer to the ballast. Starting on the down-grade end and working up-grade, the thin grout is penetrated into the stone ballast, which, as previously noted, has already been securely tamped and made to carry the strain of the passing cars. As already noted, the chute is flexible and in two sections. When a car comes along the first section is thrown out of service and the second section is lowered to the ballast at about the ends of the ties and the mixer kept in service. After the car passes the first section is thrown back in service.

It is true that during this operation some movement occasionally occurs in the tracks, but there is a city inspector on the work at all times who hunts for and locates loose ties and they are immediately tamped up with green concrete.

The natural supposition is that sufficient movement of the ties and track would occur to injure the concrete while setting, but this is not true if the work is carefully handled and executed. On one street in Baltimore this work was successfully handled with five different lines of cars passing up and down the street with but 20 seconds headway at times during the day, while on another piece of work it was successfully installed with eleven different lines of cars passing over the special work with less than 20 seconds headway at short intervals during the day. The resultant mixture is about 1 of cement, 2 of sand and 5½ of stone, with the concrete very dense, as the ballast has been thoroughly tamped and voids reduced to a minimum.

This ends the work of the railway company, as after this section of concrete is installed, the paving contractor again takes charge, installing the concrete base for the pavement immediately on top of the railway base, and then the paving.

Bond Between Slab and Base

As a rule, there is no bond between the paving slab installed by the railway company and the paving base installed by the paving contractor, because generally the former is several blocks ahead of the latter, and in the meantime the concrete slab has set. This therefore overrules the second claim of the traction officials, and the penetration method pursued meets the third claim.

One of the principal points gained by this form of construction is that it shows up very clearly every weak place during the progress of the work. All loose or poorly tamped ties are made apparent by the bubbling or oozing up of the grout as a car passes over. Failures in finished pavement are avoided by immediately tamping such ties, which in many cases would otherwise have been overlooked. It has been found by careful cuts made in the finished work that this grout when properly applied penetrates the ballast to the subgrade, forming excellent concrete, and insures solid track construction, free from vibration, upon which the life of any pavement in the railway area depends.

From records kept and compiled by the Paving Commission it has been found that the total extra cost of this construction over plain ballast, including labor and material, is about 52 cts. per lin. ft. of single track.

In the last two years about 10 miles (single track) of such construction has been installed in the City of Baltimore by this process, in the busiest streets of the city, and car traffic interfered with to such a limited extent that you hear no complaint whatever from the traveling public during the course of the work. Included in the 10 miles of single track will be found all classes of paving within the railway area—sheet asphalt, wood block, granite block, vitrified block and scoria block.

Type of Pavement.—It has been suggested that this subject could properly include a discussion as to the type of pavement between and adjacent to the rails which has been found most satisfactory. The most satisfactory type of pavement in the railway tracks on heavy traffic streets is granite block, with a cement filler. Excellent results have been obtained in Baltimore with the recut granite. The old blocks are from 8 to 14 ins. in length. The 8-in. blocks are re-headed, while the 14-in. ones are split, making altogether, blocks smaller and much more uniform in size than the standard new block. The result is a very uniform, even surface, an excellent pavement for track areas.

On streets which may be half business and half residential, or in the retail districts, vitrified blocks should be used.

All block pavements should be laid on a cement-sand cushion.

On strictly residential streets of very light traffic sheet asphalt has been used, but the speaker rather deplores the use of this material within the track areas.

The block pavements are usually laid between the extreme outer rails, including the dummy, with two rows of liners on the outside of each outer rail. Selected granite block, on a mortar bed, is most desirable as liners on heavy traffic streets. On streets of lighter traffic and residential streets, wood block, 4½ ins. deep, thoroughly embedded in the concrete and on a mortar bed, give most excellent results as liners and an excellent finish to the street, particularly where sheet asphalt is laid from the rails to the gutters.

In order to cheapen the cost of track paving our policy the latter part of last year was to install sheet asphalt in the dummy strip, where there is very little traffic, and which will give good results if the track work is stable. We will follow this policy almost exclusively this year, as a modification of our former standard, where asphalt is used between the rails and curb.

Track Details.—The rails are usually of the Trilby type, 105 lbs. to the yard, 7 ins. deep, with a slight bevel on the outer paving edge. With this rail, and the use of steel tie plates and screw spikes, tierods may be eliminated, and by the elimination of the rods better results from a paving point of view are obtained. Tierods are a nuisance in track paving, causing a great amount of cutting if a block pavement is used, and usually have to be placed below the center of the rail in case sheet asphalt is used in order to have them in the concrete instead of in the binder.

Comparison of Mixing and Penetration Methods.—Good construction could unquestionably be obtained by the rerouting of the cars, either by means of a third track and cross-overs or by diverting the cars to other streets, thereby allowing the concrete to be placed by the ordinary mixing method and at the same time allowing time for the concrete slab to set before car traffic is again restored. While this method is a safer way, it is much more expensive than the penetration method. Unquestionably excellent results have been obtained by the latter method such as has been described, its attractiveness being that it is cheaper as to first cost, owing, principally, to the economical manner in which the materials can be handled, and it overcomes the principal objection of traction officials, namely interruption to car traffic, which is of course a serious objection.

In order to obtain good results with the penetration method, every detail must be carefully looked after by the inspectors, such as the quality and size of the stone composing the ballast, the tamping, and the mixing and placing of the grout. Frequent test holes should be cut in order to see that thorough penetration is secured, and wherever possible the penetration should be started at the down-grade end of a block and proceeded with up-grade.

Conclusions.—Under the old system of earth foundation or ballast, failures and troubles were numerous. Under the new system of concrete under the ties, installed as has been described, the percentage of trouble is infinitesimal, the principal defects being at crossings and around special work. It proves conclusively that for strictly up-to-date permanent construction, both for the street railway system and the pavement, the ties should be laid on a concrete base, from 6 to 8 ins. in thickness, and completely enveloped in the same.

The Western Canada Marble and Tile Company, Limited, Winnipeg, Man., have been incorporated.

Trade Inquiries

Names and addresses of inquirers may be obtained on application from the Department of Trade and Commerce, Ottawa.

177. **Asbestos cement building sheets and roofing shingles.**—A Glasgow firm would like to have direct quotations from manufacturers.

178. **Trinidad asphalt felt roofings.**—A firm in Glasgow is open to receive direct quotations from Canadian firms.

191. **Steel products.**—A Glasgow firm wishes to receive quotations for mild steel billets, blooms, slabs and sheet bars, mild steel round bars, etc., Siemens-Martin wire rods, Siemens-Martin soft drawn wire, bolts and nuts, rails, nails and kindred products.

203. **Mild steel.**—A Glasgow firm wishes to receive quotations c. i. f. Glasgow on mild steel butt welded tubes 1¼-inch o/d by 10 W. G. thick in lengths 13 feet, 13 feet 6 inches, and 14 feet, cut to dead lengths; also mild steel sheets from 13 to 17 W.G. to length and width which will be given, and mild steel bars 1 inch by 3-16 inch; 1 inch by ¼ inch; 1½ inch by 5-16 inch; 1½ inch by ⅜ inch; and 2 inches by ⅜ inch, also 15/16 diameter.

204. **Mild steel sheet bars or billets.**—A Glasgow firm wishes to receive quotations c. i. f. for the above 8 inches, 10 inches and 12 inches wide by 11 pounds to 50 pounds per lineal foot from 15 to 16 feet long. Are open to negotiate business to the extent of 1,000 tons weekly.

206. **Galvanized iron.**—A Scotch firm asks to receive quotations from Canadian exporters.

207. **Steel wire**—A Renfrew firm desires to hear from Canadian exporters of steel wire.

209. **Agency for iron and steel.**—A Glasgow firm formerly representing German exporting houses, wishes the agency of a Canadian iron and steel manufacturer with a view to future business. Territory: Scotland and the North of England. Best references.

Pro Patria

Lt.-Col. Stewart, senior member Stewart & Witton, Architects, Hamilton.
Col. Stewart is O. C. 86th Machine Gun Battery.

Personal

Mr. W. H. Fairchild, of Brantford, Ont., has been appointed city engineer of Galt, Ont.

Mr. S. C. Oxton has been appointed deputy minister of public works for the province of British Columbia in succession to Mr. C. H. Dancer, who has retired.

Lieut. Col. Henry E. Lordly, engineer in charge of construction of the Lachine Canal, Montreal, has been appointed as O. C. to organize a battalion of pioneers. The headquarters are at the Engineers' Armory, Point St. Charles.

Mr. J. L. Busfield on March 9 gave an interesting address before the Montreal Branch of the Canadian Society of Civil Engineers on the importance of architecture and exterior design in railway stations. Mr. Busfield was formerly assistant engineer in charge of the department of design when the Canadian Northern were preparing plans for their new terminals.

Mainly Constructional

Omer Frechette, contractor, Montreal, Que., is dead.

The Stanley Steel Co., Ltd., Hamilton, Ont., have obtained a charter.

The Frost Steel & Wire Co., Ltd., Hamilton, Ont., have obtained a charter.

The London Gas Power Company, Limited, London, Ont., have been granted a charter.

The Modern Heating & Engineering Co., Ltd. Montreal, Que., have been incorporated.

The D. B. Fegles Engineering & Construction Company, Fort William, Ont., have commenced.

Mr. Ross Thompson, a prominent builder and contractor of Simcoe, Ont., died on March 10.

The Phoenix Iron Works, Limited, has been incorporated; head office Vancouver, B. C.; capital stock $10,000.

The Security Engineering and Contracting Company, Limited, is a newly-incorporated Montreal concern with a capital stock of $25,000.

Mr. Charles H. Conery, of Guelph, Ont., who was well known all over Ontario and the West as a successful paving contractor, died on March 10th.

The Montgomery Faultless Hose Reel Company, 47 Gore Vale Avenue, Toronto, have been awarded the contract for 18 hose reels for the Royal Victoria Hospital, Montreal, Que.

A fire of unknown origin destroyed the old pier No. 2 at Halifax, N. S., on March 14, and the shipping facilities of the port will be somewhat hampered for a short time. The loss is estimated at $50,000.

The Compagnie Saint-Louis, Limitee, has been incorporated with a capital stock of $20,000 and head office in Montreal, and will carry on business as general contractors and builders. The company will also deal in engineers', builders', and contractors' supplies.

Edward Pelletier & Son, Quebec, have secured the contract for the construction of a chimney in segment blocks on Monnoyer's system, for the Monastry of the Franciscan Fathers, Quebec. The height of the chimney will be 70 feet, with a diameter of 30 inches at the top.

Plans to make Niagara Falls a city that will be in keeping with the world-famous scenic wonder already provided by nature were discussed at a recent meeting of the council of the Niagara Falls Board of Trade. Mr. Thomas Adams, the town planning expert of Ottawa, is to be consulted.

According to Richardson Builders, the contractors, the new University residence at Saskatoon, Sask., is to be completed in time for the fall term. Plasterers have been doing portions of the work for some time, but a larger force is now to be engaged so that the work may be pushed ahead.

La Compagnie Castonguay, Limitee, is the name of a newly-incorporated firm of general contractors with head office at Pointe-aux-Trembles and a capital stock of $10,000.

Satisfactory progress is being made on the new bridge spanning the Trent River at Trenton, Ont. The steel frame work is about completed and in position. It is confidently expected that the bridge will be in shape for travel when the river breaks up. It will be an up-to-date structure in every respect.

R. H. Fair, road superintendent, Frontenac County, reports an expenditure of $21,416 during 1915 on the Good Roads system. Major J. M. Sheppard, of Welland, states that that county expended last year $231,367, of which the Government grant amounted to $77,222; about 83 miles have been completed out of a total of 133, at an average cost of $5,000 a mile.

The sum of $240,000 has been voted by the Quebec Legislature for iron bridges. It was stated by the Hon. L. A. Taschereau that since the Government commenced its policy of helping municipalities, 356 bridges had been constructed at a cost of $2,200,000; 37 are in course of construction, at a cost of $500,000; and grants have been made for another 27. While the contracts are let by the municipalities, the Government usually make grants of half the cost, and in some instances these are on a higher scale.

A new bridge over the Niagara River is projected in the bill incorporating the Ontario-Niagara Connecting Bridge Company. Mr. E. R. Wood of Toronto heads the list of incorporators, which includes Robert P. Slater, merchant, of Welland; W. E. D. Mackenzie, merchant, of Chippewa; Alexander Fraser, barrister, of Niagara Falls; Edward G. Counette, president of the International Railway Company, Buffalo; F. O. Dudley, attorney, Niagara Falls, N.Y.; and A. J. Porter, president of the Shredded Wheat Company, Niagara Falls, N. Y. The bridge is not to be constructed until approved by the Canadian Government and the U. S. Congress, but the company may in the meantime acquire the lands and submit their plans to the Government.

At the 13th Annual Convention of the American Road Builders' Association held in Pittsburg recently the following resolutions were passed: That this association invites the attention of State, county and municipal authorities to the value of traffic censuses as a means of determining the relative values of various forms of pavement and road construction and would strongly recommend that systematic traffic censuses be taken from time to time on all classes of roads and pavements in order that more definite knowledge of the economic value of the different types of construction may be obtained. That this association urges that laws be passed and enforced in each state establishing reasonable limits for the weight, dimensions and speed of heavy motor vehicles.

Mr. George Bury, vice-president of the C. P. R., in the course of a short visit to Toronto recently, looked over the progress of work on the new Union Station site and the new station of the C. P. R. at North Toronto. Mr. Bury expressed himself as well satisfied with the work at both stations. He said that the contractors are expecting to commence installing the steel work about April 10, after which the remainder of the work will be rushed ahead. The station, said Mr. Bury, will be one of the finest on the North American continent.

Contracts Department

J. Durham has let the general contract for the erection of three residences to George Bailey, 79 McKay Avenue. Approximate cost, $15,000. Brick construction.

Woodrooffe, Ont.
In connection with the residence which is being built by F. Harry, the contract for electrical work has been let to P. Ackroyd, 416 Bank Street, Ottawa.

Power Plants, Electricity and Telephones

Alberta Province.
The Department of Public Works, Edmonton, have made provision in their estimates for telephone construction, estimated to cost $250,000.

Kintore, Ont.
The Village Council propose to construct a transmission line from Thamesford to Kintore. Clerk, William Crellin.

Lyndhurst, Ont.
G. E. Roddick intends to construct a transmission line from Lyndhurst to Delta, a distance of five miles, and will require transformers and No. 6 copper wire.

Mt., Forest Ont.
The Mt. Forest, Wellington and Grey Telephone Company propose to build a number of extensions to their system. Manager, J. B. Moon, Mt. Forest.

Port Dover, Ont.
The Town Council will ask the Hydro Commission for estimates on the installation of a light and power system. Clerk, James Sloan.

Toronto, Ont.
The Toronto Hydro Electric Commissioners 226 Yonge Street, will receive tenders until March 28th for the supply of Watt Hour Meters. Specifications at office of the Purchasing Agent, 15 Wilton Avenue.

The Toronto Hydro Electric System, 226 Yonge Street, propose to do a considerable amount of underground conduit work this summer. Estimated cost, $85,000.

CONTRACTS AWARDED

St. Albans, Que.
The Portneuf Hydro Electric Company have let the contract for hydro equipment for their new plant to William Hamilton, 179 Reid Street, Peterborough, Que.

Fires

Birchcliffe, Ont.
Residences of A. Partridge and Thomas Holm. Loss, $1,500 and $1,200.

Calgary, Alta.
Incinerator owned by the City. Loss, between $10,000 and $15,000.

Campbellton, N. B.
Hotel Waverley, Water Street, owned by A. J. Gorman. Totally destroyed.

College Bridge, N. B.
Residence of P. D. Vinneau, totally destroyed. Loss, $2,500. Will rebuild at once.

Cyrville, Ont.
Convent of the Sisters of Wisdom, totally destroyed. Loss, $8,000.

Forest, Ont.
Marble works owned by J. Rupp.

Fruitvale, B. C.
Hotel owned by W. R. Mellard, completely destroyed. Loss, $8,000.

Gleichen, Alta.
Business block, tenanted by Beach Saddlery, Bray's Hardware Store, Cosgrove Hardware Store, Farmers Supply Company, Masonic Rooms, Corey Law Office, Central Telephone Office. Loss, about $100,000.

Grafton, Ont.
Residence owned by the Misses Cameron totally destroyed.

Halifax, N. S.
Pier No. 2, owned by the Department of Public Works, Ottawa. Loss, about $50,000.

Hamilton, Ont.
Factory of the Diamond Glass Company. Loss, about $4,000.

Montreal, Que.
Sawmill owned by Pauze & Gohier, 1822 Cote des Nieges Road. Loss, $7,000.

Neepawa, Man.
Store owned by John Brown & Sons. Loss, about $14,000.

New Liskeard, Ont.
Hall owned by J. Grills and used as a Salvation Army Barracks, totally destroyed.

Renfrew, Ont.
Factory of the Renfrew Machinery Company totally destroyed with contents. Loss estimated at $100,000. Will rebuild immediately.

St. Andrews, Ont.
Cheese factory owned by S. G. Lawson. Loss, $5,000.

St. Catharines, Ont.
Cuthbert Pattern Works, Brewery Street. Loss, $3,000.

St. George, Ont.
Storage building owned by R. Bell & Son Company, Ltd. Loss, $10,000.

St. Remi De Tingwick, Que.
Parish church entirely destroyed. Loss, $22,000. Will rebuild at once. Curate, Rev. J. O. Melancon.

Stoney Point, Ont.
Residence of Peter Mailloux.

Stettler, Alta.
Barracks of the Royal Northwest Mounted Police entirely destroyed. Owned by the Department of Public Works, Ottawa.

Stratford, Ont.
Office, furnace room and store room at the factory of the Macdonald Thresher Company. Loss, about $5,000.

Tillsonburg, Ont.
Shoe store of H. Swartz, Weeke's barber shop and Gerow's restaurant

Miscellaneous

Elmira, Ont.
Otto Rudisluela is receiving prices on a hand-power freight elevator. Capacity, 4,000 pounds.

Galt, Ont.
The Town Council are considering the purchase of a motor fire engine. Clerk, Joseph McCartney.

London, Ont.
Fire Chief John Aiken has been authorized to purchase 1,000 feet of rubber lined hose and a number of fire alarm boxes.

Montreal, Que.
Tenders on the supply of cement, sand, concrete, stone, gravel, rails and angle bars will be received until noon, March 24th, by the Secreary to the Harbor Commissioners, David Seath, Common Street. Engineer, R. W. Cowie.

CONTRACTS AWARDED

Hamilton, Ont.
The City Council have awarded the following contracts for supplies:—vitrified brick, Metropolitan Paving Brick Company, Campden, Ohio; cement, Alfred Rogers, 28 King Street W., Toronto; asphalt, Warner Quinlan Company, 79 Wall Street, New York; creosoted wood blocks, Creosoted Block Paving Company, C. P. R. Building, Toronto; sewer pipe Hamilton & Toronto Sewer Pipe Company, Ltd., Wentworth Street .. and Sackville Hill, 52 Elgin Street.

Kingston, Ont.
The following contracts for supplies have been awarded by the City Council:—cement and lumber, Frontenac Lumber & Coal Company, Ontario Street; hardware, W. A. Mitchell, Princess Street; rubble Stone, Rody & Monk, Patrick Street; sand, Kingston Sand and Gravel Company, Raglan Road; sewer pipe, Hamilton & Toronto Sewer Pipe Company, Hamilton; one concrete and asphalt mixer, F. D. Cummer & Son Company, Cleveland, Ohio, at $6,500.

Quebec, Que.
The contract for the construction of a monnoyer ferro-concrete chimney for the Franciscan Brothers, 180 Grand Allee, has been awarded to Edouard Pelletier & Fils, 111 Colomb Street.

Vancouver, B. C.
The City Council have let the following contracts for supplies:—cement, Balfour, Guthrie & Company, 739 Hastings Street W., Evans, Coleman & Evans, Ltd., 407 Granville Street, and Winch & Company, 739 Hastings Street W.; castings, Vancouver Engineering Works, 519 Sixth Street W.

Gasoline Locomotives Safe in Tunnel Work if Properly Run

Gasoline locomotives used in mine and tunnel work may develop a quantity of carbon monoxide as great as 5¾ per cent. of the piston displacement, which makes them dangerous to health if operated in headings where a good ventilating system is lacking. This occurs, according to O. P. Hood and R. H. Kudlitch, who have just completed a careful series of experiments announced in Bulletin 74 of the U. S. Bureau of Mines, only when the locomotive is running at full load on an excess of gasoline. The maximum efficiency for the weight of gasoline consumed, and also the least amount of carbon monoxide, was reached when the locomotives tested were running at 85 per cent. of capacity on a mixture just rich enough to avoid back-firing. Consequently it appears that if locomotives of excess capacity be operated so as to obtain the greatest fuel economy, there is no danger, in using them in tunnel headings, from the highly poisonous gas, carbon monoxide. The quantity of this gas given off under these conditions amounts to one-third of 1 per cent. of the piston displacement. To reach this condition for any given load and position of throttle the operator should close the needle valve until occasional backfiring occurs and then open it just enough to prevent further backfiring. If a first-class ventilating system exists there is little danger from carbon monoxide poisoning in any case, but the locomotives should be operated in the manner outlined because of other considerations. When running as described the cylinders stay cleaner. When the cylinders become coated with carbon it interferes with the cooling system, causes trouble with the spark plugs, and induces overheating. This in turn results in disagreeable "smoke" from burning lubricating oil. In addition to fuel economy the life of the locomotive is increased by careful operation.

According to these men, American gasoline locomotives are not entirely safe in headings where gas or dust is present in sufficient quantities to form an explosive mixture with the tunnel air. American manufacturers have not yet appreciated the demand for a locomotive that is entirely proof against the emission of flames from the muffler or carbureter, and against sparking outside the cylinders. Such locomotives, having closed ignition circuits and other devices, are in use in Europe, and are considered perfectly safe under any conditions in which men are able to work.

Gasoline for locomotive use should not be stored underground in pump chambers or other places where the ventilation is poor. These experiments show, however, that where there is a good current of air the gasoline, even if spilled in quantities, will not evaporate fast enough to produce an explosive mixture.

Improvised Blow Torch Heats Concrete Inside the Mixer

An improvised kerosene blow torch with its flame directed into the mixed barrel employed for heating the concrete aggregates on New York subway work during cold weather was described by Robert Ridgway, engineer of subway construction for the Public Service Commission, in a paper read before the twelfth annual convention at Chicago of the American Concrete Institute. The paper quoted a report by Andrew Veitch, assistant division engineer of the commission, on this device.

The U. S. Realty & Improvement Company and the Rapid Transit Subway Construction Company, contractors on Seventh Avenue for routes 4 and 38, sections 5 and 6, are using, as described in this report, an attachment placed on the mixer which forces a flame or hot blast directly into the mixer, thus raising the concrete to the desired temperature while it is being made. Almost any degree of heat may be obtained by leaving the materials in the mixer different lengths of time. If the heat tends to dry out the mix, sufficient water may be added to maintain the right consistency for use.

The apparatus itself consists of the ordinary kerosene blow torch inserted in a large pipe placed at the hopper through which the heat is forced and directed into the mixer. A 30 gallon kerosene tank is placed on top of the mixer, from which the oil feeds into the burner. Here it is vaporized and burns, the flame being forced into the mixer by a blast of compressed air. This air is supplied by a direct connection to the contractors' air lines feeding the rock drills. It is evident that in using this method the contractors are able to make a considerable labor saving in eliminating rehandling of the materials to heat them. Also it is possible to save much space formerly required on the street for this purpose, as with this arrangement materials can be mixed and placed as fast as they are delivered from the docks or store yards.

Concrete Pavement Struck Crosswise at Steel Expansion Joints

In building a concrete road at Tonowanda, N. Y., a novel method was used to bring the Baker steel expansion joints at the exact level of the surface of the concrete, or slightly below it. The men operating the strike board were instructed not to work closer to the joint than 2 feet, but to be sure to leave the concrete around the joint a little high. The clamps holding the several parts of the point together were left in place for more than half an hour. The finishers were then required to wade in the unsurfaced strip of concrete next the joint, and, by the use of 3 foot straightedge, cut the concrete down to the level of the finished pavement adjoining, using the top of the steel joint as a template to support one end of the straightedge. In this way no abrupt changes in level were possible at the joints, and the concrete was made to meet exactly the top of the steel.

Submit Report on Building District and Limits for New York

The commission on building districts and restrictions appointed by the Board of Estimate of New York City to consider and report on a districting plan for the purposes of regulating the height of buildings, the area of courts and yards, and the location of trades and industries has just issued a progress statement of its plans and filed detailed maps showing the suggested districts and proposed limitations. If the report of the commission is adopted by the Board of Estimate after public hearings, it will become law.

The commission desires thorough study of the proposed plans, and urges property owneds and civic organizations to inspect the proposed district maps with reference to their particular localities, so that mistakes can be avoided and the proposed maps perfected before submitting them to the Board of Estimate. Edward M. Barrett is chairman of the commission and Robert H. Whitten is secretary. George B. Ford is consultant to the commission, which has in its membership representatives of the real estate and civic interests of the city.

Keep the Home Fires Burning

The all-important work of the British Empire to-day is a vigorous, systematic, well-organized prosecution of our war. This applies equally to Canada, as the most important colony of the Empire. Yet Lord Shaughnessy says he is not satisfied of the wisdom of raising a half-million men at the present time and by the present methods.

Now, people are apt to listen when Lord Shaughnessy talks. Some way or other we Canadians have got into the habit of believing in this big man who does things. So, when he makes a public statement (which isn't often) we have felt that it carries the weight of a tremendously wide and ripe experience backed by sound common sense. If there is any one outstanding figure in this Dominion to whom the word "can't" is a stranger, it is surely Lord Shaughnessy. He is Canada's big man—big through hard work, undoubted ability, unconquerable determination, unlimited confidence in Canada and in Canada's resources.

* * *

And now along comes Lord Shaughnessy's statement that he is not satisfied of the wisdom of raising half a million men in Canada for military service under the present system. The press is saying, and some of our politicians—mere opportunists by comparison—that Lord Shaughnessy is all wrong.

Are two soldiers poorly equipped and badly trained of more value on the fighting line than one properly equipped and sufficiently trained? If so, Lord Shaughnessy is wrong. Are two soldiers without munitions better than one with plenty? If so, Lord Shaughnessy is wrong. Is a half-million soldiers, weakly supported by a country of crippled industries, better than half that number vigorously backed by the money and the ample products of a country whose industries are healthy, vigorous, and thoroughly organized? If so, then Lord Shaughnessy is wrong.

But, we believe Lord Shaughnessy is right. Is it not possible, indeed is it not apparent, that undue pressure is being brought to bear to take our valuable men from their regular avocations before they are actually needed? We have many men ready for overseas who have not been called. Why not, at least, divide their time, meanwhile, between industrial and military work? We have actually reached the point where our wheels of commerce are beginning to slow up for lack of man-power—much of which, apparently, is going to waste right around us every day. On all hands we hear the industrial cry for more men. "We can't get sufficient men to fill our orders," they are all saying. And if this is true to-day, what will it be like in another six months or a year, if recruiting goes on under the present haphazard auspices? The answer is all too plain. Our factories will be crippled, our farms will be depleted, our industries of every kind—the backbone of our strength, whether in peace or war— will be driven to the wall.

We shall have a big, unwieldy fighting machine without any "punch."

* * *

We believe Lord Shaughnessy is right, and we believe just as strongly that present recruiting methods are wrong. It is a system that no man defends, a system that no one approves. It evidently exists simply because it existed, and because our Government is so conservative, so unbusinesslike, so evidently unwilling (whether incapable or not, we cannot say) of taking a man's grasp of a man's job. Under the present system of recruiting, the men who answer the call of duty are of course the men who recognize their duty. They are thus the men who count for most at home—the men who can least be spared—the men whose removal causes the biggest rift in our industrial life.

And our Government sits quietly by. Young men, with no ties and no responsibilities and in many cases occupying positions from which they could readily be spared, stand back and allow the ranks to be filled by our artisans, our captains of industry and our professional men. It is this the Government is defending. It is this also Lord Shaughnessy, no doubt, has in mind when he criticizes.

Of course we are going to win this war—why shouldn't we? We are immensely richer both in men and money. But are our enemies going to force us to use all our men and all our money just because we are badly organized? It begins to look that way. Will it then be a victory in which we can take pride in after years—a victory of mere weight of men and superior wealth? Will it even be a victory which we can follow up to advantage? Are we going to allow Germany to issue from this war, as she entered it, the best-organized nation in the world? Will we be ready to meet her competition? Or are we actually going to be too weak from lack of present organization to count in the commercial war that is only just beginning, and which will be fiercer and more prolonged by many times than the present war of men?

What Canada cries out for to-day is organization—for war, present and future. What business man goes on year after year, for example, without taking an inventory? Yet our Government takes no inventory, knows nothing about the stock in hand. Is this business? What Canada needs most urgently at the moment is an inventory of her man resources—the capacity, the responsibility, the experience, the fitness for this or that work, the ties—of every one of her citizens. Next we need an organization that can say to each man, "Your place is—there." What Canada needs is, if you like, moral conscription, which does not curtail the liberties of the citizen in any way, but simply points out in an authoritative way the path of duty. No one would oppose it; few would fail to answer such a call. It would mean the highest conservation of all our resources. It would mean preparedness, not only for this year and next, but for the years which follow. It would mean winning this war without the feeling that Germany, even though crushed, will laugh up her sleeve at the tremendous sacrifices she has forced us to make and at the exhausted condition she has left us in.

Lord Shaughnessy is right when he warns us against impairing our industrial strength. It is a vitally important question—scarcely less important than the war itself, because the two are so closely inter-related. Whatever the outcome of this struggle may be, if we come out of it badly organized, industrially weak, bereft of our most useful men, overcrowded with slackers and incapables, even when we reach Berlin—we've lost.

Canadian Industrial Campaign

The Export Association of Canada Limited, embracing over one hundred of the larger Canadian Manufacturers, is actively engaged in a campaign to create a favorable position in world markets for Canadian industry as a whole. The Association, which has been assisted and encouraged by the Prime Minister of Canada, the Minister of Trade and Commerce, the Canadian Manufacturers Association, the C. P. R., G. T. R., leading representatives of the Press, and many others who recognize to what extent the future welfare of the Dominion depends upon the building up of a sound and profitable export trade, has already opened offices in Montreal; London, Eng.; Auckland, New Zealand; and Melbourne, Australia. Representation is about to be established in South Africa.

Through the connections which it has made for manufacturers, the Association has placed regular shipments for Australia and New Zealand. The Association has been appointed Purchasing Agents in Canada and the United States for the Crown Agents of the Colonies. Important orders are being received from this source. The joint general manager of the Association in London is placing the Association in touch with important buying channels in France, Russia, Italy and Belgium, so that at the conclusion of the war, Canadian firms may have knowledge of the requirements of these markets. The Association is preparing for large business abroad when the scarcity and high rates of ocean tonnage have been overcome.

Cement Bricks

Windsor, Ont., March 21, 1916.

Editor, Contract Record:—

In reference to your article on "Cement Bricks," in the March 15th issue of your valued paper, which is always a welcome visitor to our office, the writer wishes to take advantage of the invitation therein and make a few remarks concerning the same. The writer has had several years experience with all kinds of building materials, especially those made of cement and burned clay, and any remarks made here are based on a knowledge of the facts as found in twenty-six years in the business.

First.—Cement blocks have come to stay; because they afford a cheaper first cost construction than brick—and there will always be those who will use and advocate cheapness regardless of any other or future consideration, or disadvantage.

Second.—Cheapness is the only advantage over a hard-burned clay brick that a cement block possesses. They are neither as dry nor as warm as a brick wall of the same thickness laid with blind headers. In fact you cannot keep iron, steel or leather goods in a cement building without keeping them well packed, unless the walls are lathed and plastered.

Cement concrete has a cold nature and condenses the moisture in the air near it.

Third.—I would think that the greater the pressure applied to a pressed cement brick the better it would be. Although not having any experience with pressed brick I have made enough cement brick for four houses with a machine that tamps them, and we tamped them to the limit to be sure they were solid. In spite of this we found they would stand very little teaming as they wore their corners and faces off. One very bad feature with a cement brick or block is the fact that the least settlement in a wall will cause the cement brick or block to crack straight down, whereas a clay brick wall upon settling will crack along the mortar joints only, making it much easier to remedy.

Fourth.—There is no advantage to the consumer or contractor in a frog brick, except that it is easier for the bricklayer when he has to get down to a tight joint. The bricklayer does not lay the frog down to save mortar. Generally the mortar is spread in such a way that it makes no difference whether the frog is up or down; but in laying the frog down it leaves a level surface on which he spreads his mortar, in that way making it easier to keep to the line. Another feature of the frog, is that the struck side or top side when it is in the mould, dries straighter than the frog side, and when the bricklayer strikes the joint he presses the bottom of the joint back from the face of the brick, in that way leaving that edge exposed to the view as to whether it is straight or not, generally the joint is more nearly straight where frog is laid down.

The frog was placed in the brick, not as most people think, to make the wall stronger, but to save clay in the making and burning less fuel in the kiln. The fact is, that it is much easier to get a frogged brick out of a wall than it is to get a plain brick out; the result being that the plain brick makes the strongest wall, although either will and have met with highest success in all walls for the general building. The clay brick will stand a great deal more heat and pressure than a cement brick.

Very truly yours,
(Signed) William Thompson,
Thompson Bros.

Pure Iron Culverts

Montreal, March 17, 1916.

Editor Contract Record:

We have read with interest the English translation of a paper prepared by Mr. Fraser of Quebec, and read at the Good Roads Congress under the title of "Culverts and Maintenance" and we wish to draw your attention to a common error in translation.

This refers to our Corrugated Pure Iron Culverts. There isn't the slightest doubt that in preparing his paper, Mr. Fraser intended to refer to Pure Iron Culverts, and in the English translation the reference is made to Corrugated Steel Culverts.

Our Company has never sold any Steel Culverts in the province of Quebec, all our product being made from pure iron Toncan Metal, which is nothing more or less than pure iron, from which all the corrosive elements have been practicall eliminated.

Trusting you will publish this correction in as early an issue as possible, we beg to remain,

Yours truly,
The Pedlar People Limited.
(Signed) W. E. Ramsay.

Committees Toronto Branch C.S.C.E.

At a recent meeting of the Executive Committee of the Toronto Branch of the Canadian Society of Civil Engineers, the following members were appointed to the several working committees named below:—

Roads and Pavements.—M. A. Stewart, Chairman; S. G. Talman, G. G. Powell, H. S. Van Scoyoc, W. Huber. Subject—Investigation of sand for concrete highway construction.

General Clauses for Specifications.—Willis Chipman, Chairman; E. W. Oliver, E. L. Cousins, Wm. Cross, D. Molitor. Subject—To consider last year's report and suggest modifications if desirable.

Steel Bridge Specifications.—A. H. Harkness, Chairman; Frank Barber, H. L. Steenbuch, David Molitor, Thos. Taylor. Subject—Steel highway bridge specifications.

Reinforced Concrete.—Peter Gillespie, Chairman; Frank Barber, A. W. Connor.

Sewage Disposal and Sanitation.—A. Macallum, Chairman; P. Gillespie, W. Chipman, F. W. Thorold, J. H. Nevitt. Subject—Report on Commercial Success of treating sewage by aeration.

New Members.—J. R. W. Ambrose, Chairman; H. E. T. Haultain, A. H. Macallum, G. A. McCarthy, J. H. Curzon.

Legislation Committee.—E. W. Oliver, Chairman; J. G. G. Kerry, H. E. T. Haultain.

Track.—E. G. Hewson, Chairman; A. F. Stewart, A. L. Hertzberg, F. B. Goedike. Chairman to choose work to be done by Committee.

Power Plants.—L. M. Arkley, Chairman; A. A. Bowman, Peter Bain, E. T. J. Brandon, F. G. Clark, A. G. Hill, Jas. Milne, A. L. Mudge. Subject—Uniform Steam Boiler Specifications for the Dominion of Canada.

Library Committee.—A. L. Mudge, Chairman; W. A. Hare, A. A. Bowman, Fraser F. Keith.

Hydraulics.—N. R. Gibson, Chairman; T. H. Hogg, H. G. Acres, E. C. H. Dowson, C. L. Fellows, D. Mol Pipe.

Parliament Buildings, Ottawa

Plans for the remodelled Parliament Buildings, Ottawa, have been completed and placed on exhibition to the Members of Parliament in the office of the Minister of Public Works by Messrs. Pearson of Toronto and Marchand of Montreal. Plans and profiles of the interior and exterior are more or less tentative, and have yet to receive the formal endorsation of Parliament.

The main features of the new plans are the preservation of the present architectural scheme of the whole front elevation as it now stands, the tearing down of the new west wing, which was undamaged by fire, but which did not preserve the original architectural harmony of the whole building; the construction of a new rear elevation following the lines of the original architectural scheme, but with a three-storey elevation corresponding to the front; the construction of chambers for the Commons and Senate at the west and east sides respectively, of the building, instead of in the centre, as was the case before the fire; a rearrangement of the office space in the interior, which will give 38 per cent. increased accommodation without sacrificing light or ventilation, and a main entrance hall and Court of Fame extending from the main entrance beneath the central tower clear through to the Library in the rear. This latter wide corridor will give a much more imposing vista on entering, and will afford opportunity for a national gallery of statesmen in oils and in marble or bronze.

The new Commons chamber will occupy practically the whole of the new west wing. It will be considerably larger than the former chamber, being 102 x 63, and providing ample space for some 320 members. The Speaker's chair, instead of being in the centre of the west side as in the old chamber, will be at the north end, and the gallery seating will be much better arranged, both in regard to acoustics and in regard to accommodation for a much larger number of spectators.

The members' lobby and post office will be along the front of the building, with a big lounging and smoking room running along the ground floor on the west side of the Commons chamber. Committee rooms and reading rooms will be situated on each side of the main entrance hall, running from the front entrance back to the Library.

On the Senate side the new chamber will be at the extreme east end, following the same line as the Commons chamber, but somewhat smaller. Fireproof construction and an adequate system of ventilation are being provided for. The plans will be gone over carefully by a committee of the House representing both sides before they are finally approved. It is expected that the work of reconstruction will be begun this spring.

Total imports for the twelve months ending January, 1916, were valued at $502,772,844. This is less than we purchased during the twelve months ending January, 1915, when the total was $603,771,358. For the year ending January, 1914, our purchases were valued at $661,272,527.

Bridge Construction in Ontario

The Evolution of Building Practices—Present Traffic Requirements—Choice of Location and Type—Inspection and Maintenance

By George Hogarth*

There are to-day sections in the south of the province that have been settled for over a hundred years; and in the north, there are vast areas where the axe of the first settler is only now being heard. Bridge construction in Ontario, therefore, varies from the primitive types of timber construction suitable for the lightest of traffic to the more enduring structures of concrete and steel, which are capable of safely sustaining the weight of a twenty-ton road roller.

Conditions in Northern Ontario

Our rivers of the north are usually broad and deep with nothing more secure than a shifting, slippery clay bank upon which to build abutments or piers. The crossing of such rivers is an expensive undertaking, since the river bottom is frequently soft and very liable to be deeply scoured if the current is in any way deflected by a pier. In Ontario a large number of bridges are required each year, and those large structures which are more expensive and serve only a small population must frequently give way to less costly smaller structures or ferries, which furnish communication till bridges are warranted. In deciding on the type of bridge to build, consideration must be given to the lumberman who is bringing sawlogs down the river, and piers must be located or omitted with a view to avoiding log jams. The safe location of the piers usually governs the length of bridge span to use, since the crowding of logs cannot always be prevented, and a heavy jam will often pull timber piers clean out of the river, piles and all. There is also the ice to contend with, and it works almost unceasingly to destroy any timber structure with which it comes in contact. Late in the fall, when the water is low in the river, the ice forms and sticks solidly to the piles or cribs for a depth of probably three to four feet. Should a sudden thaw come in February, the water lifts the ice and gives the piles a heave that throws the entire structure out of grade. For these reasons, it has been found advisable to bridge the rivers with one span wherever possible, and to place the abutments or piers out on the banks of the stream. The placing of piers in the river channel is usually an expensive piece of work, and the maintenance money that must be spent to protect them from logs and ice in the spring of the year is frequently considerable. The use of long span bridges is often therefore an economy.

Building Materials

There is very little gravel or rock to be found in some sections of Northern Ontario, and concrete abutments or floors cannot be considered. Practically everywhere, though, there is standing timber of fair size and quality which can be quickly cut into piles and roughly hewn to form portions of the piers and flooring. The design of structure has thus developed along the most economical lines, and to-day, you will see on the highways of the north steel bridges resting on timber piers and having a sawn or hewn plank floor. On the smaller creeks and rivers, the timber Queen Post bridge is still built, and is supported by pile piers or timber rock filled cribs; but where the bridge must be 60 feet or over in length, a steel span is the best and cheapest type of structure that can be built. The cost of labor in remote sections of the north is sometimes out of all proportion to the work done, and these types of construction have been developed from actual experience as being the most economical under present conditions. With such a type of bridge, the building of the pile piers requires comparatively little work, and four or five men and a team will finish the timber work, erect the steel span and lay the floor of an ordinary structure in about three weeks' time. Many such bridges are built in locations which are 25 and 30 miles from a railroad, and local men accustomed to the country must be employed, since the ordinary discouragements of life on that class of work drive the newcomer out of the business.

Bridge to Meet Traffic Conditions

The traffic on some of the newer roads of the north does not warrant an expensive bridge across a broad river, and in such a case a wire rope is stretched from bank to bank and a scow provided, by means of which travellers may ferry themselves across the stream. Such a contrivance is cheap and is of great use during the summer months of the year, but the crossing will be impassable to all ordinary travel for a week or so during the spring and fall.

The highway bridges built in the settled districts and counties of older Ontario are of a more advanced type of construction. They must be capable of carrying heavier loads and be built so as to withstand the wear and tear of greater traffic. Since good sand, gravel, and crushed stone are easily obtained and cement is cheap, it is economical to build the structures of concrete. For the longer spans where concrete is not as serviceable, the steel bridge is used, and it is customarily supported on concrete abutments and provided with a concrete floor.

Type of Bridge

For short spans, the concrete beam bridge is a very desirable structure, and for spans of medium length, where local conditions admit of its use, the concrete arch is of pleasing appearance. Such work, when well designed and properly built, is very durable, but great attention must be given to the foundations and to the surrounding conditions in order that damage to the structure may be prevented. Concrete is easily adapted to almost any foundation, but it is not in the best interests of such construction to use it in important locations where settlement of the piers is to be anticipated, or where the river channel will be cramped, due to a low bridge being required. The safety and enduring qualities of a concrete structure depend to a great extent on the stability of the foundations. The slightest movement of the footings will result in cracks opening in different parts of the structure, and while such cracks may not seriously affect the strength or safety of the bridge, they are unsightly and indicate an undesirable condition of affairs. Concrete is a splendid building material and will give good results even with very indifferent workmanship. It is particularly well adapted to certain locations and designs,

*Chief Engineer, Ontario Highways Department. Before Good Roads Congress, Montreal.

but if used indiscriminately failures are bound to occur. In the case of small concrete bridges, the placing of the footings at a sufficient depth below the ground or water surface is frequently disregarded. As a result, the rush of water during a freshet undermines the foundations and the entire structure may be lost. It is good practice to carry all footings down to a depth of at least four feet below low water level since at that depth the foundation will be safe from frost, as well as from the scouring action of the water. There are so many vital considerations entering into the design of a highway bridge that the selection of the type and nature of the bridge should be left entirely to the engineer and his decision should be final.

Heavier Riveted Construction

Within the last fifteen years there has been a gradual development and improvement in the general design and construction of steel bridges. The tendency has been toward strong and rigid riveted construction, and the light types formerly built have been abandoned. This progress is best illustrated in the cities by the use of heavy plate girders, and in the country by the building of fully riveted bridges in place of the pin-connected structures formerly erected. With riveted details, a longer life is to be expected of such bridges. There is still, however, room for further improvement in the design of typical connections, but the overcoming of prejudice against new methods along such lines is a slow process. Details that were considered good design twenty years ago, but which are now obsolete, may be used in structures built to-day, if care is not exercised in checking the plans. Our highway bridges are now designed to carry a concrete floor and a 15 or 20-ton road roller, or a live load of 100 pounds to the square foot of floor surface. The structure which is built to carry such loading is of good proportions with fairly stout members. In the past, insufficient quantities of metal were used in many bridges, and they were built so light as to be unable to sustain for many years the wear and tear to which they were subjected by the traffic and the elements.

Maximum Load

The tendency of the times indicates that a 20-ton road roller will be the maximum load for bridges for some time to come. In some localities it is proposed to limit the weight of road rollers and auto trucks allowed to pass over highways and to make the maximum permissible weight of such machines ten or twelve tons. Legislation along such lines appears to be advisable, since with an unrestricted weight of auto trucks we would soon see excessively heavy vehicles doing considerable damage to highway bridges. Some timber and concrete floors have already received severe treatment and have been partly destroyed by the heavy rear axle weight of loaded trucks, and unless steps are taken to curtail such weight the damage will greatly increase. It is advisable, therefore, to enact laws which will set a limit on these heavy loads so that the highway bridges can be built in the security of knowing the heaviest load they will be called upon to carry. Otherwise, great confusion may result, and a condition might arise where all our bridges would be too weak the moment an auto truck manufacturer increased the capacity and weight of his product. The establishing of a definite maximum load gives the auto builder and the bridge engineer a basis upon which to develop and improve all designs.

While we now build what is believed to be a fairly stout bridge, the required minimum thickness of metal of 5/16 inch causes nearly all highway bridge work to be known as tinwork in the shop where it is fabricated. If durable structures are to be constructed, no skimping or trimming out of metal should be allowed. It would appear to be a step in the right direction if no metal less than 3/8 inch thick was permitted to go into a highway bridge. Steel highway bridges are still built too light and flimsy to give a long length of life. Many steel bridges in use 25 years urgently require renewal to-day because of the serious rusting of the thin material, and if our work is to be enduring and have a fair length of life, it is absolutely essential that a sufficient quantity of metal be used in the new bridge.

Flooring

There are several types of flooring used on highway bridges built to-day, and probably the one most frequently placed and which gives good satisfaction is the reinforced concrete floor. The plank floor and the creosoted wood block floor are also used in cases where concrete materials cannot be had, or where it is desired to lighten the dead load on a long bridge. In laying a concrete floor, too much care cannot be exercised to see that all stone, sand, or gravel is clean and the best to be obtained, since otherwise the result will be a poor concrete which will soon show signs of wear and disintegration.

The office methods and specification data used in the design of bridges call for little or no comment, but many of the methods of obtaining first hand information in the field during the original survey or inspection of the site of the bridge, might be profitably revised. Inexperienced men should not be sent to measure up the location of a proposed bridge. Each crossing of a river is surrounded by widely different conditions, and an engineer well versed in building and maintaining bridges should make the original surveys and examinations.

History of Location

When a bridge is to be built, accurate information is required respecting the width of the river, the depth of the water, the height of high and low water, the navigation or log driving to be provided for, the manner in which the ice goes out in the spring, the quantity of driftwood brought down by the freshet, the nature of the banks of the river, the character of the foundations that will be required, the local material available for concrete or timber work, and the distance to the nearest railway station. This information is necessary, be the bridge small or large, and in addition the judgment of the engineer comes into play when the question is put as to what structure is best adapted to the site. Many instances could be cited where, owing to incomplete information, a bridge pier was placed in the middle of a river. The amount of money required to protect and maintain that pier, together with its first cost, would have paid for a steel bridge long enough to completely span the river. In some cases, bridges of insufficient length have been placed at crossings of wide rivers, and as a result they have been swept away on the crest of the first serious flood. The position of the banks of a river is very significant. They are standing evidence that, at one time or another, the river possessed sufficient force and power to sweep away everything between those banks, and a structure which cramps that wide waterway is putting up a losing fight with nature. The pages of our engineering journals continually record the washing away of bridges, and the lesson frequently placed before us is that the waterways provided at bridges should be of a sufficient size to pass the floods. The creek of to-day may be the roaring torrent of to-morrow, and provision should be made for that excessive rush of water. It is only natural to build bridges as small as possible, and to construct them with the least expenditure of money, but in building a bridge the first consideration should be the safety of the completed structure and the size of the waterway to be provided must govern the design.

Foundations

The nature of the foundation on which the abutment of a bridge is to be placed deserves mention. An engineer is called upon to construct bridge footings in every kind of location from one that is a bottomless bog to one that is splendid solid rock. There are between those extremes a number of different classes of material, all of which require close attention in order that a secure footing may be obtained. A solid rock foundation is ready for the concrete as soon as all the loose and decayed rock has been blasted and cleaned away. It is well to have the rock footing fairly level and yet rough enough to give the concrete a good bond to prevent any possibility of sliding. With a foundation of gravel, boulders, or hardpan, the concrete of the footing may be deposited when the excavation reaches a depth of four or five feet, since at that depth scouring of the material cannot occur and frost will have no effect.

Use of Piles

Where the foundation is sand, silt, muck, or soft clay, the bottom will require that piles be driven, and soundings should be made to ascertain the depth or length of pile required to bring up against hard material. In driving piles, good judgment and experience is required to know just when a pile is sufficiently driven. Many specifications require that driving shall be continued to refusal, and this is much to be preferred to under driving. The preparation of a pile foundation requires just as much care as any other part of the design of a bridge, since with improper or insufficient driving settlement will occur and the abutment or pier will be destroyed.

In some locations where an exceptionally soft foundation occurs, it is advisable to divert the road to a better crossing, where a more secure bottom can be obtained. With a highway bridge, however, there is a lack of vibration and impact and the loading is comparatively light, so that in almost all soft locations a good pile footing will be found to be all that is required to safely carry the abutment.

For short bridges up to, say, 40 or 45 feet in length, and where the bottom is soft, a steel beam bridge gives a very satisfactory structure. The small cost of the entire work does not justify expensive pile foundations, and a mat composed of long timbers may be laid in the bed of the river so that each timber extends under both abutments. A slight settlement is to be expected with such a structure, but no harm or damage to the bridge will occur.

Maintenance of Bridges

The maintaining of the many steel bridges now on the highways is a work requiring considerable experience and attention. A bridge is like any other structure built by man, it is not everlasting. In the case of steel structures, it has practically been a custom to neglect them and they are seldom painted. This neglect hastens the rusting and decay of the metal, and the day soon comes when another bridge is necessary. It is frequently a difficult matter to have councils appropriate money for painting bridges when they have seen indifferent and expensive work done on bridges in their own or in an adjoining municipality. There is no doubt whatever that money spent for painting is real economy, and there is no defense that can be offered for allowing a bridge to go to ruin. If a structure is painted every four years, it will take five complete paintings to protect it for 20 or 25 years, and at the end of that time it should be in a good state of preservation. It could then be removed to a highway having lighter traffic and would probably be of good service in that new location for a number of years. Experience with bridges that have been uncared for for 25 years, indicates that they are just about ready for the scrap heap, whereas a proper painting carried out at comparatively small cost would have rendered them still useful for an indefinite period.

Inspection

A competent inspector should examine all bridges at least twice a year. The inspections should be in the spring and fall, and every portion of the structure should be examined to discover any defects. The older bridges have many welded members, and experience has shown that such details are liable to fail while in service. Where there are two bars in a member and one breaks there is still sufficient strength available to carry the structure, pending immediate repairs, but no chances should be taken, and if there is any doubt as to the ability of the structure to stand up it should be closed till repairs can be completed. Notice boards calling attention to a speed limit on the bridge may be in place, but are, in all probability, illegible, due to disappearance of the paint. Such boards are still necessary. They should be painted with easily read type and placed conspicuously in order to obtain compliance with the stated request. The fact that a notice board cannot be read usually results in a lack of observance of a very necessary restriction on the speed of horses crossing a bridge.

Repairs

The practical test of observing the bridge during the passage of a heavy load may result in the discovery that the various parts appear to be loose and that the entire structure appears to be working or moving. If there are a number of adjustable members in the trusses and lower laterals, it is probable that the tightening of such while no load is on the structure will cure any apparent looseness, while if the bridge is fully riveted it is desirable that close attention be given the various joints to see that rivets are still tight. If a number of loose rivets are found, it is best to cut them out and re-drive so as to produce a tight joint.

In Ontario we have many concrete bridges, and where such structures were originally well built there are no maintenance charges and little or no inspection required. The first concrete arch bridge built by the Department of Public Works was constructed in 1907. It is founded on solid rock, and to date not one cent has been expended for maintenance.

In conclusion it may be said that the highway bridge is to-day in an important stage of development. The knowledge gained in using the various materials of construction is tending to modify and improve the design and general appearance of such structures, and a more artistic type is being aimed at. With an established system of loads for all structures, and a greater public demand for permanency in construction, a considerable improvement in the character and type of bridges is to be expected.

Concrete Foundations for Asphalt Pavements and Roads Subject to Heavy Travel

By Clifford Richardson*

The first essential in road construction of a permanent character is a dry and firm subsoil upon which to build. This being assured, another and more essential factor in the satisfactory construction of the highest type of asphalt pavement, country highways, and, in fact, for all forms of road surfaces to carry heavy traffic, is a suitable foundation. This is emphasized by the weights which our main arteries of communication are called upon to sustain owing to the advent of the motor vehicle, more especially the motor truck, the latter rapidly increasing in capacity to such an extent that means of regulating its use are being considered. Portland cement will, therefore, find an extended use as travel on our roads increases, for the purpose of affording adequate support for any type of surface. The only satisfactory substitute therefor has been found to be an old, well-compacted broken stone road which, in this country, is not often available, but of which good examples are found in England.

Foundation Supports the Load

In the case of asphalt surfaces, these, in themselves, possess no inherent strength to support heavy loads and, like all other surfaces, require an adequate support when subjected to concentrated travel. Whatever type of pavement or road surface, of a character to carry heavy travel, may be selected, it must, unquestionably, be given such support by a proper foundation, and this can be accomplished in no more satisfactory way than by a suitable Portland cement concrete. While this has been recognized for some years, in certain instances, it is plain that it must have a general acceptance in the near future, at least as applied to our main arteries of communication, while it is generally desirable as a matter of permanence, where funds are available, in view of the much longer life which any form of construction will have if placed thereon. The primary difficulty is, of course, the availability of funds for this purpose. As a well constructed Portland cement foundation needs no maintenance its cost may be met by the issue of long term bonds. Such a procedure would violate all principles of economics as applied to the surface itself, the life of which, for any type, cannot be such as to justify a bond issue for a longer period than ten years.

Thickness of Concrete

The thickness of concrete which is called for as an adequate support for a road or street is, of course, dependent upon the character of the travel it will be called upon to carry and upon the support which it receives from the sub-soil on which it is placed. In London, England, on one of the streets of the heaviest traffic, High Holborn, it has been proposed to place 11 inches as being a thickness necessary for the conditions to be met there. The usual thickness in this country for our most important thoroughfare has been six inches, but with the enormous disturbance which is continually going on for underground operations and with the increasing weight of the motor truck this will, in the near future, have to be increased in proportion.

At the same time, it is becoming recognized, at least by experts, that there must be a great improvement in the methods employed in the selection of the aggregate, especially the sand, of which concrete is made. Testing the sand is as important as testing the cement if work of the highest character is expected. It has also been demonstrated that one brand of cement will give more satisfactory results with one sand than with another, although each cement will yield the same results with standard sand. It is evident, therefore, that there is a great opportunity for improvement in the character of concrete and it is encouraging to know that the United States Office of Public Roads and Rural Engineering and several specialists on the subject are making extended investigations in this direction.

Permanent Investments

A Portland cement concrete foundation may be looked upon as a permanent investment and, to a certain extent, concrete road surfaces may be also considered in the same way, as when they become too rough with age to be used as such they will, with adequate repairs, become available as a foundation for an asphalt surface or one of some other type.

California, under the policy pursued by its State Highway Commission, is expending millions of dollars in the use of Portland cement concrete for highways, and looks upon this expenditure as an asset for many years. Upon this concrete an asphaltic surface, composed of sand and fine pea-grit, is laid for the purpose of obtaining one which is more agreeable for travel at a cost of but 8 cents per square yard. This is a temporary expedient where the travel is light and funds are not available for a more suitable form of construction. It is expected to last for three or four years and give an adequate return for the money expended. Where travel is more concentrated, an asphalt surface mixture containing fine stone is employed, costing about 50 cents per square yard, which may be looked upon as having a higher degree of durability. Probably there is no State where as satisfactory a combination of Portland cement concrete and bitumen has been used, looked at from the point of view of economics, as in California, although it may be regarded as too thin, having a thickness of only 4½ inches. This is, of course, due in part to the favorable climatic conditions which the form of construction employed there is called upon to meet.

It is worthy of note that where Portland cement concrete is protected by a bituminous or other form of surface, a much smaller proportion of the hydraulic binding material and a lean concrete is called for, than where it is exposed to travel and is, consequently, much less expensive.

Careless Mixing and Placing

Experience has shown that our present methods of mixing and placing concrete for road construction may be improved to a very large extent. Too much work of this description is carried out carelessly, without a proper study of the mineral aggregate of which the concrete is composed and without devoting sufficient time to its thorough mixture, but engineers are awakening to their shortcomings in this respect and there

* Before American Concrete Institute, Chicago.

will no doubt be a great improvement in this direction in the future.

Of course, the characteristics of the Portland cement in use in concrete foundations for road surfaces and the degree of fineness to which it is ground, form an element of great importance in the success with which concrete is employed for any purpose, although it is recognized that the product of our American industry is generally of a very high quality.

Climatic Conditions

Climatic conditions and the great extremes of temperature, at times ranging from 130 degs. F. to 40 degs. F. below zero, result in the formation of cracks in Portland cement concrete when used as monolithic foundations for asphalt surfaces, and these are often reproduced in the surfaces themselves, but the effect of such cracks usually disappears within the first few years of the life of the surface and are not subsequently manifested to any disagreeable extent. That these cracks are largely due to contraction, due to extreme temperatures, is demonstrated by the fact that they are far less apparent in such a climate as that of California where extreme temperatures do not occur. In certain instances expansion of Portland cement concrete, at joints between different day's work, have been observed, but this happens but rarely and, again, is not manifested after the expiration of a few years' time.

Progress Report on Nova Scotia Water Power Investigations—Establishment of Meteorological Stations

By K. H. Smith*

PROBABLY more small water power developments, such as saw mills, grist mills, and carding mills, have existed in Nova Scotia than in any other part of Canada. However, in common with all other countries, before the advent of long-distance electrical transmission, interest in water powers was purely local until the year 1909, when public interest in water powers was sufficiently aroused to influence legislation. Previous to 1910 no reservations had been made of the waters of the beds of rivers or lakes comprised within land grants. Moreover, by that time the greater part of the public domain had passed into private hands.

In the meantime the activities of the Hydro-Electric Power Commission of the province of Ontario, as well as those of private concerns in other parts of the country, did not go unnoticed in Nova Scotia, and in 1909 an act was passed indicating that public interest was alive at least to that particular phase of the possibilities of utilizing hydro-electric energy in Nova Scotia. A culmination of public discussion and interest in hydro-electric energy so far as Nova Scotia is concerned seems to have occurred during the 1914 session of the local House of Assembly.

Appointment of Commission

The consideration of bills passed at that session led to considerable discussion along general hydro-electric lines, and the concensus of opinion seemed to be that something should be done in Nova Scotia to determine whether or not a hydro-electric policy similar to that carried out in Ontario by the Hydro-Electric Power Commission could be inaugurated to good advantage in Nova Scotia. Accordingly an Act was passed in the latter part of the session which provided for the appointment of a Nova Scotia Power Commission to make certain investigations and recommendations.

The Commission was organized in accordance with the Act, and met on July 31, 1914. Following several conferences between officials of the Dominion Water Power Branch and representatives of the Commission, a co-operative agreement was reached. The Commission was to have the services of an engineer of the Dominion Water Power Branch, with his expenses and necessary field equipment, while the Commission was to make available the sum of $3,000 for the first year's work. The writer, K. H. Smith, as engineer of the Dominion Water Power Branch, was instructed to proceed to Halifax as resident engineer in charge of all work to be undertaken.

Conferences were held in Halifax on April 20 and 21, 1915, between Mr. J. T. Johnson, chief hydraulic engineer of the Dominion Water Power Branch, the resident engineer, and the members of the Commission. Active work was begun on May 10, 1915, when gauging stations were established on some of the rivers, and since then both field and office work has progressed without interruption.

Available Power

It is apparent that an adequate estimate of the water power possibilities of any stream depends mainly on two things; first, the head or fall available; second, the amount of water available. The amount of water available may be influenced by the possibility of storing flood flows to increase the low water flow. The first factor, that is, the head or fall, as also the question of storage in lakes or artificial basins, is constant, and may be determined absolutely by instrumental surveys. The second factor, that of the amount of water available, is variable, and depends entirely on the rainfall, the amount of water which runs off in the streams being further influenced by local conditions of temperature, wind, geological formation and vegetation. A gauge is installed at a suitable location, indicating the height of the surface of the water at its various stages. By means of an instrument, known as a current meter, registering its revolutions electrically, the velocity and depth of the water is obtained, at various stages of the stream as indicated by the gauge. Having determined the area of the cross-section of the stream and the velocity of the water, the volume of the water flowing at each of these stages can therefore be computed by a simple multiplication of these two factors and this result or "run-off" is usually indicated in cubic feet per second or as it is frequently abbreviated, "second-feet." By tabulating in a special way a relatively small number of these measurements, distributed from low water to high water, the amount of water flowing in the river may be determined for all stages, by merely reading the gauge. For this purpose, local observers are employed at small expense, who read the gauges on the various streams, usually once a day and more often at special seasons.

* Resident Engineer Dominion Water Power Branch, Halifax.

The amount of rainfall is measured in a cylindrical vessel suitably located, and requires attention from an observer at each period of rainfall.

Gauging Stations

So far as possible, gauging stations are established not only on representative streams in the district, but also on streams which are of themselves important. At most of these stations daily gauge heights are obtained with additional records at critical periods of flow. In one or two cases, records twice a day are obtained. In addition to this all the larger water power developments of the province with one or two exceptions, and including all pulp mills and all hydro-electric plans supplying various municipalities throughout the province have been personally examined. From every possible source data with respect to existing water power developments is being collected and tabulated. Considerable progress has been made in this work. A rough reconnaissance has been made of nearly every part of the province, in order that the detail work might be more intelligently distributed. A small map is appended showing approximately the locations of all precipitation and stream gauging stations.

Satisfactory Progress

It is thought that with the exception of the island of Cape Breton, representative stream flow statistics are being obtained throughout the whole province. The present system of stream flow recording stations should, however, be considered merely as a framework with many parts to be more completely filled in as time and funds permit. Several additional stream gauging stations will be established during the immediate future under arrangements with the Meterological Service, or by means of voluntary observers already available. Funds will also probably be available for one or two additional paid observers.

A report will be prepared for the Dominion Water Power Branch covering the work accomplished to the end of March 31st, 1916. This will contain complete and detailed information of stream flow available to that date. It will also include detailed reports on the power possibilities of a number of streams, which reports will be as complete and comprehensive as data available to that date will permit. It is believed that in the beginning that has been made, foundations have been laid for satisfactorily carrying the work to completion, and it is hoped that arrangements will be made whereby the present run-off and power studies will be continued until the entire province has been systematically covered and its water power resources conclusively determined.

New Union Station, Toronto

Satisfactory progress is being made on the new Union Station, Toronto. The excavations for the foundations have been completed, and the concrete caissons and piers have been entirely installed. Machine rooms, furnace rooms, boiler rooms, etc., have been excavated, and the east and west wings are ready for steel. The centre section will be completed and ready for steel in about two weeks.

The foundation work was done by Peter Lyall & Sons, the general contractors. All foundations were carried down to bedrock; there are no clay-bearing foundations in the whole plan. In excavating, water was encountered in practically all the foundations, due to the proximity of the site to the lake. These were kept dry by the use of pumps and siphons. Service tracks for superstructure erection are already laid, and some of the structural steel and the erection derricks are already on the ground. Setting the steel bedplates is expected to commence on April 1, and the erection of the structural steel about April 20.

New York a Gilded Tragedy

(Sydney Brooks in North American Review)

To come from England to Manhattan Island, from a country strung up as never before in its annals to the heroic pitch, full of the spirit of sacrifice and endurance and in daily touch with the grimmest facts of life and death—to come from such a country and to land in New York is to make a change indeed. For New York, always a feverish and pleasure-loving city, is to-day simply drunk with money. Even during the height of the steel boom of twelve or thirteen years ago, when every train from the west seemed to bring fresh carloads of brand new millionaires, the metropolis was not so openly reeling with dollars as it is at this moment, when the gayest "season" of its history is drawing to a close.

It almost appals an Englishman to find there in full swing the old rotten life that we in England have put completely behind us. And it appals him still more to reflect that a bare two years ago he was leading, if one allows for the extra intensity that New York throws into all its activities, very much the same life himself. One despairs of ever being able to convey to one's American friends how completely the war and its conditions and consequences has become not merely a part of, or a side issue to, but literally the whole British existence. They are so dominant, have so utterly swallowed up everything else, that no other form of life, least of all the trivial carelessness of peace, seems normal or even credible.

I catch myself in New York, if I enter a lighted room, instinctively reaching out to draw down the blinds lest a Zeppelin raider should note the glare; and of all the sights that crowd in upon me, that of multitudes of young men who are not in khaki strikes me as the strangest and the most repellent. It may be one more proof of our demented state, but it is the bare fact that not for anything would we in England change places with you in America or part with the waste and misery of the war to receive in return the "blessings" of such a peace as yours. Stay-at-home Americans simply cannot enter into or even conceive the atmosphere of the belligerent nations in this struggle; and conversely, so long as it lasts, a visitor from any one of the countries at war will continue to be shocked by the atmosphere of America as something unnatural to the point of being grotesque.

In New York the fact and the vastness of this chasm of sentiment assail the visitor with the sharp finality of a bayonet thrust. Louvain and Rheims are among the stricken victims of the war, but New York is its supreme and gilded tragedy, and has, I fear, neither the sense nor the soul to know it. Americans must by now have heard of the English charwoman whose husband was at the front and who was drawing her weekly separation allowance. She was asked what she thought of the war.

"What!" she replied. "A pound a week and no 'usband! Why, it's 'eaven! It's too good to last!"

There is something in New York's attitude towards the war which reminds one of this simple soul.

Ammonia in the Chlorination of Water—Effect of Color, Turbidity and Temperature

By Capt. J. Race*

In the course of some experiments on the effect of color, turbidity, and temperature on the chlorination of water, the author thought it would be interesting to determine the relative efficiencies of various hypochlorites. Nothing worthy of mention was observed until ammonium hypochlorite was used; this was prepared in solution by the double decomposition of calcium hypochlorite and ammonium oxalate, and great care was exercised to prevent the addition of an excess of oxalate, which, if present, would introduce a factor of unknown value. It was anticipated that the reaction would proceed somewhat along the lines represented by the following equation:

$$Ca(OCl)_2 + (NH_4)_2C_2O_4 = CaC_2O_4 + 2NH_4OCl$$

calcium hypochlorite, ammonium oxalate, calcium oxalate, ammonium hypochlorite

The calcium oxalate was deposited by centrifuging at a high speed and the supernatant liquid removed for experimental work.

In testing the effect of this solution on a culture of B. coli communior seeded into raw Ottawa River water, the author was very surprised to find that the germicidal value was very much in excess of the hypochlorites of calcium, sodium and potassium. The velocity of the reaction as calculated by the formula

$$K = \frac{\log \frac{N_1}{N_2}}{t_2 - t_1}$$

in which N_1 represents the number of organisms at t_1, and N_2 at t_2, showed that, with 0.3 parts per million of available chlorine in each instance, the value of K for ammonium hypochlorite was twenty to thirty times as great as that of calcium hypochlorite. This experiment was confirmed by others, which gave similar results.

In searching for an explanation of this phenomenon it occurred to the author that it was probable that ammonium hypochlorite was exceedingly unstable in dilute solution, and spontaneously decomposed into chloramine and water, as represented by the following equation:—

$$NH_4OCl = NH_2Cl + H_2O$$

ammonium hypochlorite, chloramine, water

Chloramine has been shown by Rideal (Journal of the Royal Sanitary Institute, 1910, 31, 33-45) to have a much greater germicidal action than an equivalent of chlorine. Rideal deduced this fact from experiments on the chlorination of sewage, in which he found that "the first rapid consumption of chlorine or hypochlorite was succeeded by a slow action which continued for some hours—even days— and was attended by a germicidal power after free chlorine or hypochlorite had disappeared. . . . " "It became evident that chlorine, in supplement to its oxidising action, which had been exhausted, was acting by substitution for hydrogen in ammonia and organic compounds, yielding products more or less germicidal." Rideal supported this by determining the carbolic coefficients of hypochlorite, and of hypochlorite with the addition of an equivalent of ammonia; these gave values of 2.18 and 6.36 respectively. Although Rideal seems to have made this experiment merely for the purpose of explaining an observed phenomenon, it is curious that the possibilities of its practical application to water and sewage disinfection seem to have either been entirely overlooked or discarded on account of economic considerations.

Ammonia Content

After noting the above-mentioned facts in connection with ammonium hypochlorite, the author followed up Rideal's work and produced dilute solutions of chloramine by the addition of ammonia to calcium hypochlorite solutions. These had the same germicidal power as the chloramine produced by double decomposition, and were approximately three times as efficient as an equal quantity of hypochlorite.

The next step was to determine the relative proportions of hypochlorite and ammonia that would yield the greatest efficiency. The results obtained, though not entirely conclusive as to the most efficient ratio, showed that an increase in the ammonia beyond an equivalent of the chlorine (available chlorine: ammonia as $NH_3 = 2:1$ by weight) did not produce results commensurate with the increase of ammonia. Half an equivalent of ammonia, or chlorine: ammonia $= 4:1$ gave inferior results, but the reduction in efficiency was very much smaller than the reduction in the ammonia. The relative proportions of chlorine and ammonia must also be considered from the economic standpoint, and when this process is carried out on a large scale these various considerations will demand a rather fine adjustment.

A remarkable feature of the treatment of water with a mixture of hypochlorite and ammonia is the almost entire absence of absorption. On adding bleach to the Ottawa River water, so as to produce a mixture containing 10 parts per 1,000,000 of available chlorine, about 35 per cent. is absorbed in five minutes at 60 deg. Fahr., and 60 per cent. within one hour. If an equivalent of amounts is first added to the bleach, only 1.4 per cent. of the available chlorine is absorbed in one hour and 3.2 per cent. in twenty hours. As there is practically no absorption of the germicidal agent, the longer the contact period the better will be the results obtained. For instantaneous sterilisation, the relative efficiency ratio of 3:1 for the mixture of chlorine and ammonia as compared with chlorine cannot be obtained, but with increase of contact period the efficiency ratio also increases, and after about forty minutes the ratio becomes greater 3:1. The germicidal action of the mixture continues to persist on account of non-absorption, and for a comparatively long time, and as a consequence of this, no after-growths are produced.

Cost

Basing the calculations on a ratio of one equivalent of ammonia to one equivalent of avaliable chlorine (0.5 part per 1,000,000 NH_3 to 1.0 p.p.m. available chlorine), a very conservative estimate of the most efficient ratio, this process becomes economical when the price of hypochlorite exceeds $2.00 per 100 lb.

* Canadian Army Hydrological Corps, in "Surveyor."

This statement is based on the mixture produced being three times as efficient as hypochlorite; that 33 per cent. of available chlorine can be obtained from bleach, and that ammonia can be purchased for 1s. per lb. The efficiency ratios of 3:1 can be obtained under the conditions of chlorination usually found, and no alteration in the point of application will be required. Bleach containing more than 33 per cent. of available chlorine can be obtained, but very few plants actually extract more than this amount, as there are certain losses which are unavoidable. The present price of ammonia aqua. 16 deg. B, is quoted in the U. S. A. at 2¼ to 2½ cents per lb. This solution contains 10.3 per cent. of NH_3, and the anhydrous ammonia is therefore worth 22 to 25 cents—or approximately 1s. per lb. In Ottawa, bleach can be obtained for $3.50 per 100 lb., and, by the adoption of the ammonia process, the heavy dosage of 1 part per 1,000,000 of available chlorine required to treat the Ottawa River water (color, 40 p.p.m., platinum scale) can be reduced to 0.33 p.p.m., with a saving of about $6.70 per day, or $2,400.00 per annum, if the laboratory results can be duplicated under service conditions. In the United States, where much higher prices prevail for bleach, the advantage to be gained by the substitution of the ammonia process is, of course, even greater.

Aesthetic Consideration

For some years it has been considered as at least probable that the fishy odor and taste of heavily chlorinated water was caused, not by the chlorine or hypochlorite, but by substituted nitrogenous compounds. At first sight it would appear that by the addition of the substituted nitrogenous compounds contained in the ammonia mixture this objection would be accentuated and deprive the process of its practical value. In practice no such result is obtained, and no trace of the added mixture can be detected. As the total amount of chlorine added to the water is only about one-third of the usual dosage, the total amount of chlorine compounds, nitrogenous and otherwise, is only one-third also, and complaints regarding taste and odor should be reduced, and not increased, by the adoption of the new process, unless the compounds produced are totally different in the two cases.

Since writing the above the author has applied the above process to a small plant treating 200,000 Imperial gallons per day, and has met with unexpected difficulties. When a 10 per cent solution of bleach was made and strong ammonia (0.880) added, a rapid loss of available chlorine resulted. This was reduced considerably by diluting the hypochlorite solution before adding the ammonia, but even then the results were not satisfactory. Laboratory experiments confirmed the loss produced by mixing comparatively concentrated solutions, and also that the loss could be obviated by immediate dilution with large volumes of water. The arrangements in the experimental plant are now being altered so that the ammonia and hypochlorite will only mix for a few seconds before dilution with the raw water in the intake pipe.

Although various details have yet to be worked out, these notes are published in the hope that others will take up this work and endeavor to work out a process that will give some relief from the present exorbitant price of hypochlorite.

High Level Air Lift Pump at Quebec Bridge Discharges 5,000 Gallons per Hour Against a Head of 500 ft.

THE interesting air lift plant here to be described has been installed for supplying the Transcontinental Railway yards at the Quebec Bridge. The neighborhood of the magnificent St. Lawrence would seem to be an anomalous location, but several considerations operated to determine the installation. The rise and fall of the tide, the height of the embankment and the unsuitability of the river water were important points, and besides this the use of the river water would have necessitated the construction of a pumping plant at a distance from the power house, and would have increased the cost of attendance.

Work was started in September, 1912. Forty-three feet of 8 in. wrought iron pipe was driven from the surface to the rock, and from that point a 5-in. bore hole was started. The well was drilled entirely in shale, red and gray alternating.

On September 30th a depth of 400 ft. had been reached, and a rough pumping test yielded 200 imp. gal. per hour. At 280, 520 and 700 ft., respectively, dry crevices were encountered, while at 775 feet water was struck in considerable quantity. The hole was then reamed to a diameter of 8-in., and a subsequent test yielded 3,200 imp. gal. per hour.

At a depth of 980 ft. another water crevice was opened up and at a depth of 1,012 ft. drilling was discontinued. The whole well was then reamed out to 8-in. diameter. A large plunger pump was used for a 24-hour test, and with 400 ft. of rods in the well a yield of 5,400 imp. gal. per hour was maintained. This pump was afterwards operated for eight days to clean out the well, and a sample of water was analyzed and reported satisfactory for both boiler and domestic purposes.

When the well is not being pumped water rises to the surface; when being pumped to capacity it drops, however, to a depth of 400 ft. from the surface.

A joint contract was awarded to Canadian Ingersoll-Rand Co., Limited, and Williams and Wilson, Limited, of Montreal, for furnishing and installing a suitable pumping plant. The air-lift system was adopted owing to its numerous advantages over other systems of deep-well pumping, as with this system there are no moving or wearing parts in the water, and the air-compressor may be located at any distance from the well.

In lowering the pipes and foot-piece, which were extra heavy, great care was required because of the weight; but there was no mishap of any kind.

The air-compressor is a Canadian Ingersoll-Rand tandem compound steam-driven machine, designed for a terminal pressure of 250 pounds, and the air cylinders are fitted with a new type of valve known as the circo-leaf valve, which is absolutely noiseless in operation. The frame is fully enclosed, and the moving parts work in a constant flood of oil. A combined speed and pressure governor controls the compressor.

The air-lift foot-piece was manufactured by the

* Compressed Air.

Harris Air Pump Co., of Indianapolis, whose pumps are extensively installed throughout Canada. The column of water is carried by an air-jet situated below a choker, which arrangement eliminates slippage and causes the air to be distributed through the water in small bubbles. The booster pump was also furnished by the same firm.

Water is discharged into a steel tank 24 ft. in diameter, and the total capacity, including the leg, is 61,170 imp. gal. The level of the water in feet is indicated by a marker on the outside of the tank, and by this means it is possible to accurately gauge the capacity of the plant. The tank is supported by a steel frame resting on a concrete base, in which are located the valves and connections to the service mains and to the main drain. Steam is furnished to the compressor at 110 lbs. pressure.

Owing to the depth to which the water drops in the well three air lines are used, two being tapped into the water discharge line at different depths, and the third entering the Harris foot-piece. Each of these three air lines is controlled by a gate-valve in the power-house, and the engineer operates the system without going near the well, which is 250 ft. from the power-house. A gauge over each line shows the pressure and indicates the fall of the water in the well.

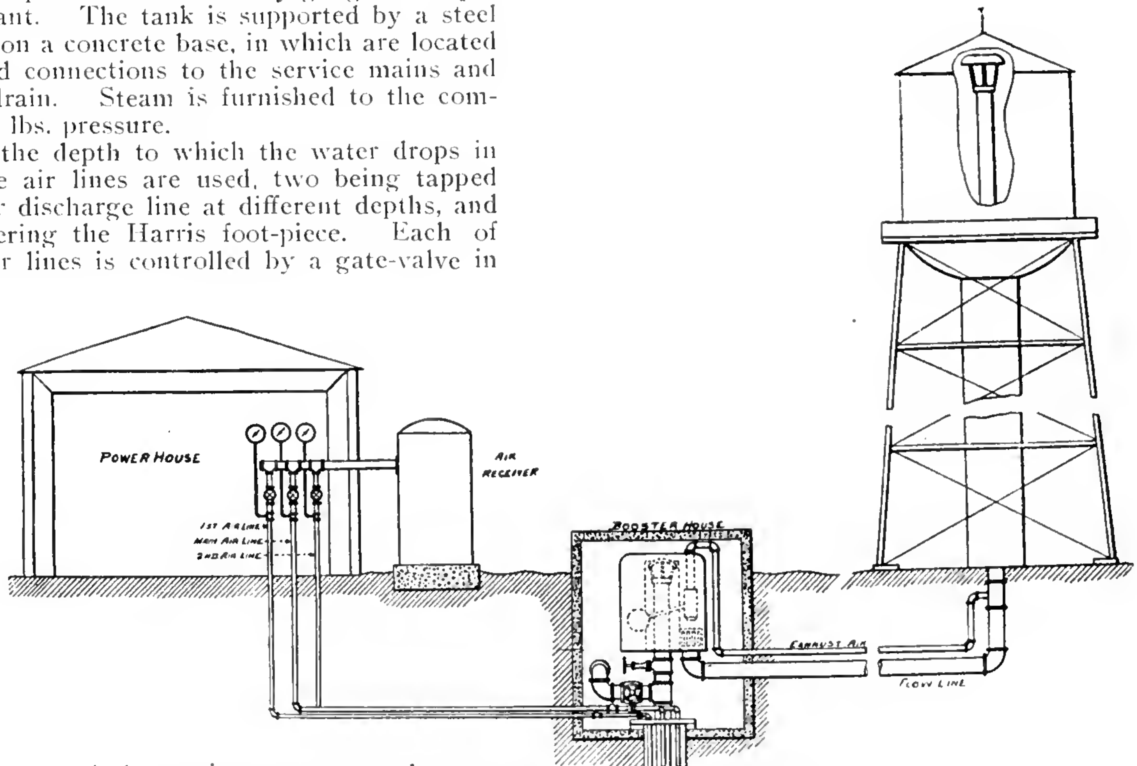
Air discharges from the compressor into a high-pressure air-receiver and from there to the well. The first air line starts the water flowing and continues to pump until the well lowers as far as this line is capable of lowering it. Then the first air line is gradually turned off until the second line begins to act. When this line has lowered the water as far as it is capable of lowering it the work is taken up by the third line and the second line is closed. The third line, which is the main pump line, then continues to furnish air as long as the system is in operation.

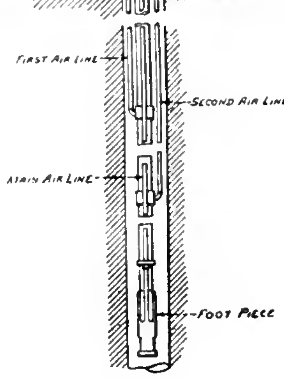
The object of the first two lines is to enable the accumulation of water in the well to be pumped away without resorting to an abnormally high air pressure. These lines are only used in starting the system.

The yield of the well is 5,400 imp. gal. per hour delivered into the tank, and under continuous operation the air pressure at the receiver is about 160 lbs. When the system is first started the yield reaches a total of about 6,000 imp. gal. per hour, this being due to the accumulation of water filling the well to the surface. The yield gradually decreases under continuous operation until the normal capacity and pumping head are reached.

At the surface the water has to be pumped horizontally a distance of 60 ft., and subsequently to a height of 90 ft. into the top of the steel tank. For this work a Harris booster operates in conjunction with the air-lift.

This booster consists of a steel tank resting on the top of the well-casing and receiving the water as it discharges from the well. The operating parts consist of a float and valve located inside the tank. The water and air are separated in this tank, the air rising to the top and maintaining sufficient pressure to force the water to the elevated tank. As the solid column of water discharges the float drops, allowing the sur-





Air-lift pump at the Quebec Bridge—pumps 5,000 gals. per hour against a head of 500 ft.

plus air to exhaust from the tank. This whole operation requires only a few seconds, as a discharge takes place every time the booster is about two-thirds full. In fact, practically a constant flow is maintained.

The surplus air may be piped back to the compressor intake or discharged into the vertical riser to lighten the column of water and reduce the operating pressure. This latter plan was followed in the case of the plant at Quebec. The booster is automatic in operation and requires no attention. It also operates without noise. This apparatus is located in a concrete sump below the ground and is reached through a door in the roof. A by-pass is connected to the main drain so that the well can be pumped directly into the sewer for cleaning purposes.

The plant was operated by the contractor for several days under the supervision of Mr. Alex. Porter, Assistant Engineer of the Transcontinental Railway, who at the completion of the test said the plant was entirely satisfactory, and the most reliable of the various railway divisional pumping units.

The high lift in this case is a noticeable feature, amounting to about 500 ft. vertical and 60 ft. horizontal. It demonstrates as far as it goes that there is practically no limit to the height to which the air lift will raise water if a fair amount of submergence is obtainable.

On a test recently the plant pumped nearly 6,000 gal. (Temp.) per hr., but this capacity was due to accumulated water near the well. The normal capacity (5,000 gal. per hr.) was developed continuously after the level dropped to 400 ft. At this point the running pressure was 160 lb. per sq. in. The highest pressure required for starting was 225 lb.

The Functions Performed by Stone in Bituminous Concrete Pavements

By R. B. Gage*

If the maximum amount of service is to be secured from any bituminous concrete pavement, it must not only be constructed by experienced men using first-class equipment, but the various ingredients composing it should be so proportioned and blended that on the one hand the benefits to be secured by the use of each will be the maximum, while on the other the injury that they may cause will be reduced to a minimum.

An examination of some of the specifications now in use describing this particular class, shows quite plainly that some of the pavements defined therein will not give as efficient service as could be secured by using the same ingredients in different proportions. These variations in grading are not the result of careful preliminary determination of the conditions to which the pavement will be subjected, with a subsequent selection of the particular grade best suited to combat these conditions. The usual object is to secure a pavement that can be constructed at a very low initial cost and yet possess all the merits of a first-class bituminous concrete pavement.

If the real value of such pavements is to be determined by the service rendered, it will be necessary to wait until their merit has been thus demonstrated before passing judgment. It is seldom that they begin to show any serious signs of failure before they are three or more years old, unless they have been laid on very inadequate foundations or were of exceedingly bad construction. During this interval a large quantity of this same grade of pavement may be laid if the firm or contractor representing the same is very aggressive. When failures begin to appear in the original pavement laid, the contractor may have gone out of business or have disappeared. Another grade is then substituted for that previously laid which may at the end of three to five years, prove to be equally as unsatisfactory as the former.

Selection of Ingredients

If errors of this kind are to be prevented, it is necessary to determine before selecting the grading just what functions are performed by the ingredients to be used. Once these have been determined it becomes possible to so proportion the ingredients that the maximum amount of benefit will be secured by their use. That this type of pavement possesses merit, when the ingredients are properly blended, has been repeatedly demonstrated and quite conclusively proven even when subjected to very adverse conditions. The numerous premature failures have also shown that if the ingredients used are not properly blended the life of these pavements will be shortened accordingly.

In the surface of a sheet asphalt pavement but three ingredients are needed, i.e., sand, filler and asphalt cement. The diameter of the largest size sand grains seldom exceeds 0.1 in. These grains have a hardness of 7 and will absorb little if any water. With a given sand the percentage of asphalt cement used is confined to fairly narrow limits. The same is also true of the filler. The life of such a surface is greatly lengthened, and its ability to resist creeping and decomposition, caused by water attack from beneath, is much reduced by laying the same on a binder course. The thickness of these surfaces varies from 1 in. to 2 ins., being generally about 1½ ins. It is not uncommon to find pavements of this type in fairly good condition after twenty years of service. Even when subjected to quite severe traffic they will last from 10 to 15 years with very little repairs, yet the original surface was not over 2 ins. thick and contained no ingredients over 0.1 in. in diameter. It is thus seen that the life or wearing properties of a bituminous pavement is not dependent upon the use of stone in the wearing surface.

Defects

If this pavement could be judged by its durability and resistance to abrasion, it would be ideal, but unfortunately it possesses certain inherent defects. It is slippery when wet and quite brittle during cold weather. On account of this brittleness a very rigid foundation is required. The grading of the aggregate calls for the use of a greater quantity and of a harder asphalt cement than is used in a bituminous concrete pavement. A greater quantity of filler is also needed. These are the most expensive ingredients used in bituminous pavements. The use of a binder course also increases the cost of construction and makes the repairing of holes more difficult than with a single course pavement.

When a certain per cent. of the aggregate of a bituminous pavement consists of broken stone larger in size than 0.1 in. in diameter, it possesses more inherent stability and density than a pavement, the aggregate of which is all smaller than 0.1 in. in diameter. The amount of inherent stability thus imparted to a pavement will vary with the size and quantity of the stone used and its thickness. On account of the added stability thus given the pavement a much softer asphalt cement can be used than in a sheet asphalt pavement and a binder couse is not necessary to prevent creeping. The percentage of voids and surface area of the

* Before the American Road Builders' Association, Pittsburgh.

aggregate can also be so reduced that about 4 per cent. less asphalt cement will be required. By using a fairly soft asphalt cement such a pavement is given sufficient elasticity and pliability during cold weather to safely allow the use of a base having a limited amount of movement. The stones contained in these pavements also prevent their surfaces from becoming as smooth and slippery as a sheet asphalt surface.

It is thus seen that the principal function of the stone are:

First, to give the pavement increased stability.

Second, to allow the use of a softer asphalt cement.

Third, to reduce the percentage of voids and surface area of the aggregate.

Fourth, to eliminate part of the slipperiness in the surface during wet and cold weather.

The first allows us to dispense with the binder course; the second admits of the use of a base that is not altogether rigid; the third reduces the quantity of asphalt below that required with a pure sand mix. All of these reduce cost.

The influence of all of these factors will naturally change with the stone content. If the maximum stability and minimum void content should be fixed between fairly definite limits. The larger sized components of the aggregate should be present in sufficient quantity to form the skeleton or framework of the pavement. The quantity required for this purpose will vary with the size, shape and grading of stone used. The greatest density is secured when the smaller sizes of the aggregate are present in sufficient quantity to just fill the voids in the larger sizes. This is best accomplished by using a fair proportion of stone whose largest dimension is about one-half the thickness of the pavement. The percentage of voids in the stone will generally be between 30 and 45 per cent., consequently the stone content of the aggregate should be from 55 to 70 per cent.

Percentage of Voids

If the fine aggregate is not present in sufficient quantity to fill the voids, the pavement is not as dense as would otherwise be the case and may not be waterproof. As the quantity of the fine aggregate is increased over that needed to fill the voids in the stone, the inherent stability is decreased and the void content in the total aggregate is correspondingly increased. If there is a considerable excess of the fine aggregate the stone simply floats in the mortar aggregate and the principal reason for its use is thus destroyed. If the use of stone did not introduce conditions injurious to the pavement, little harm would be done by its use excepting to increase the cost of the pavement. However, since a danger is thus introduced which may shorten the life of the pavement considerably, it becomes very important that the quantity of stone used should be such that the maximum benefits will be secured by its use.

The sand grains in a sheet asphalt pavement, as above stated, are practically impervious to water, have a hardness of 7 and are practically free from any definite planes of cleavage. The stone used in a bituminous concrete pavement will not meet the requirements of such a standard. Trap rock has a hardness of about 6, shows planes of cleavage and is not impervious to water. Granite, limestone and dolomite are softer yet, have more pronounced lines of cleavage and are much less impervious to water.

When in use, the thin bituminous coating is worn off the faces of the stone. The porosity of the stone is increased by being more or less shattered by the shocks of travel. When unprotected faces are thus exposed, the stones become saturated whenever the pavement surface gets wet. Moisture is thus carried into the body of the pavement and attacks the bitumen. The rapidity of decomposition of the bitumen depends first upon the porosity of the stone, and second upon the ability of the bitumen to resist hydration and oxidation. The bond between the bitumen and the stone is first destroyed and then the layers of adjacent bitumen are decomposed. When the bond between the stone and asphalt cement has been thus ruined the stones will drop out of a section of pavement when it is broken open like nuts from their shells. No trace of asphalt cement can be seen on them and their surfaces are usually bright and clean.

Quality of Stone

Certain types or grades of stone are often selected for an asphalt pavement on account of their open texture or porosity which allows the asphalt cement to penetrate into the surface of the stone to a slight extent. In this manner a better bond is supposed to be secured between the asphalt and the stone. This appears to be a step in the wrong direction, for the more porous a stone the more moisture it will absorb. A good asphalt cement will adhere to sand grains even when they are fairly smooth. No broken stone possesses any such polished surfaces. The denser, harder and tougher a stone is, the better it is adapted to fulfill the functions required of it in a bituminous concrete pavement. No trouble has ever been experienced in securing a good bond between an asphalt cement and the hardest and closest grained trap rock found in New Jersey.

In the original Topeka-Sterling specifications, if the aggregate retained on the 10-mesh sieve is designated as stone, we find that not less than 8 nor more than 32 per cent. of stone can be used. In the modified Topeka specifications recently adopted by the American Society of Municipal Improvements, the stone content may vary between 20 and 30 per cent. Each of these specifications gives a bituminous mixture in which the stones simply float in the sand aggregate. Both of these gradings give a pavement which possesses all the defects inherent in a bituminous concrete pavement and some of those peculiar to sheet asphalt, with few if any of their respective virtues. They have not the stability or density of a properly graded bituminous concrete, require a greater quantity of asphaltic cement, are more brittle and slippery, and lack the uniformity and endurance of sheet asphalt. It is claimed for these pavements that they do not infringe on certain patent rights. This certainly is not sufficient to justify their use. If their value is to be determined by the service rendered, much time and expense will be saved by selecting types of construction whose value has been definitely proven, even if the initial cost be somewhat higher. The saving in initial cost which may be made by using an improperly graded pavement is soon lost if the pavement fails prematurely. In such cases those responsible for its selection or construction are usually severely criticized and not without reason.

Exports from Canada were valued at $85,559,782 during January of this year. In January, 1915, the exports were $30,830,337, and in the same month in 1914, $29,861,359.

More Artistic Designs for Concrete Bridges

The time has arrived when we should expect our local public works to be constructed with a neater and more finished appearance, to show a degree of refinement and finish that all citizens can aspire to copy in their private undertakings. It is only too common today to see a highway bridge recently built in an extremely rough-shod and slovenly fashion.

The causes for the poor outward appearance of many of our bridges are: lack of sympathy on the part of the community for something better; failure on the

An Artistic Concrete Bridge with Simple yet Graceful Lines—A Direct Contrast to Many of our Highway Bridges.

part of the engineer to enforce specifications; lack of efficient inspection; incompetence on the part of the contractor or foreman. Some of the most prominent and flagrant defects so far as appearance are concerned are: the edges and corners not being chamfered off, they become broken and jagged; the forms are built loose and insecurely braced, and the surface of the concrete improperly spaded, the result being distorted walls, with rough, honeycombed surfaces; and the use of mortar to patch up or plaster honeycombed surfaces. These results are generally due to the use of poor materials, and poorly supported forms, which allow the concrete to settle while setting, lack of care to obtain a proper foundation, and misplacement of the steel reinforcement.

In direct contrast to these flagrant defects, the artistic possibilities of concrete are clearly set forth in the illustration, artistic in its simplicity of design. Concrete bridges can be moulded with pleasing lines at a slight increase in cost over a structure with plain, straight, ungraceful lines.

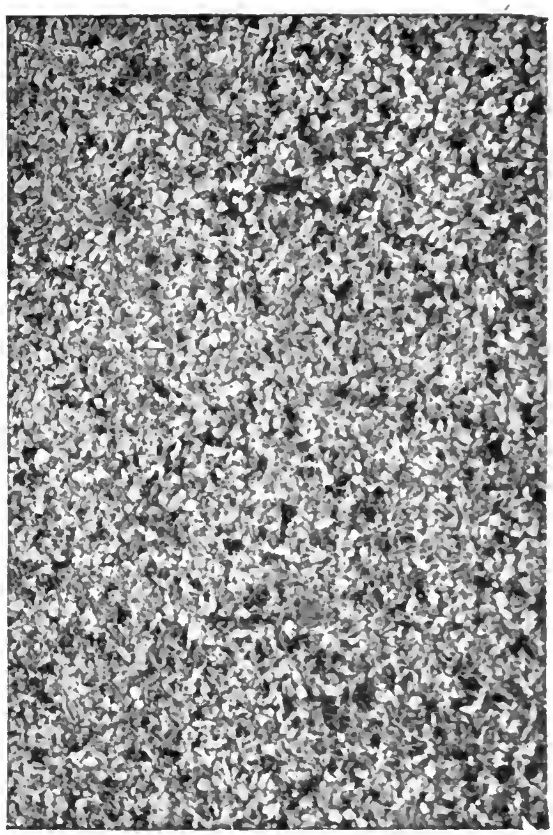
The structure shown is designed with two slightly arched girders, having a span of 54 ft. 5 ins. and a width of 14 ft. between parapets. The abutments are founded on ferro-concrete piles extending up to the under side of the girder span, where they are connected by capping, being monolithic with the decking of the bridge. The main girders are combined with the parapets, the total depth of the two being 5 ft. 7 ins., thus providing great depth and strength in the most economical manner possible. Transverse beams connect the main girders, and the structure is completed by a continuous decking slab 4 ins. thick, the whole being a monolithic connection throughout.

Water Softening by Electricity

Water softening by electricity, especially as regards boiler feed water, is attracting the close attention of American engineers. After the softening compound has been added to the water it is circulated past parallel electrodes which are placed close together in order that as much of the water as possible may be brought in contact with the surface of the plates. The ionising properties of electricity separate the compounds into their components, thereby hastening the recombination to form precipitates, which are easily removed. Ten million gallons of water per day, it is stated, may be treated with only 480 watts per million gallons.

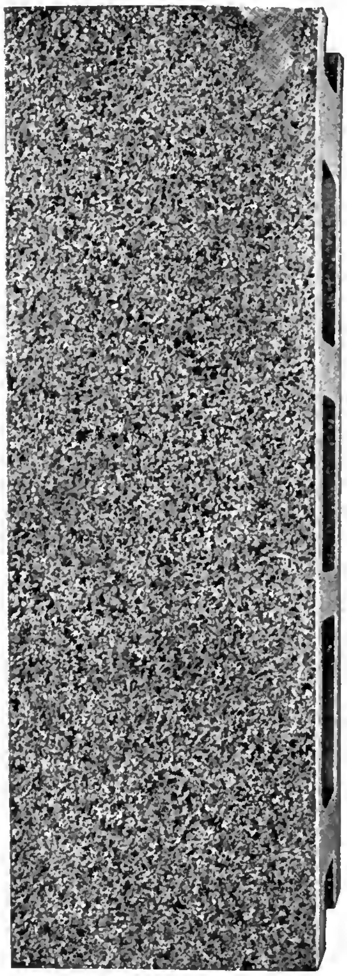
Cast Stone System of Manufacturing Cement Blocks

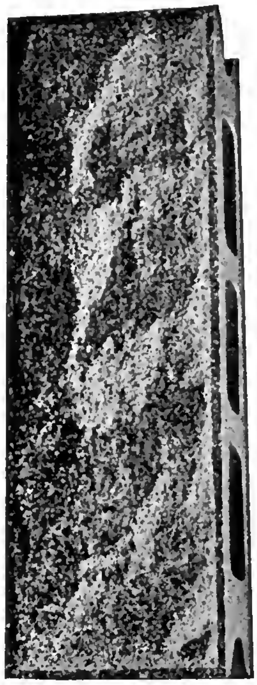
The illustrations herewith represent the products of the Cast Stone Block and Machine Company, of Windsor, Ont., who manufacture machinery for doing this work, and also operate a large cement block plant in that city. By the cast stone system you can make waterproof blocks with granite veneered facing, either rock or smooth, at less cost, it is claimed, than you can turn out an interior block by any other process. The manufacturers state that these have greater strength and durability. The appearance, as shown in the illustrations, is also very attractive. The granite-faced blocks are not an imitation product, but are cement veneered with pure granite, possessing strength and hardness equal to a solid granite block. The man-



Cast Stone Block, Veenered with Granite Crystals.

ufacturing of granite veneer is an interesting process. A face plate is first coated with thin glue, then covered with crushed granite. This company procure their granite from the quarries at Crown Point, on the Hudson River, N.Y., which is claimed to be the most beautiful and practical for this purpose of any rock or facing material known. After the glued plate is covered with granite it is turned over so that all loose particles may drop off, after which the plate is set away for a short time while the glue hardens. The moulds are then set up in the usual way, but just before they are filled the granite crystals that are now firmly held on the face plates by the hardened glue are given a coating of pure cement mixed with water to the consistency of a thin paste. This coating is applied with a brush, the purpose being to embed the crystals in a layer of pure cement. The moulds are then filled with slush concrete and the mixture left to harden. While the cement is setting the water from the wet concrete softens the glue, and the blocks when taken from the moulds are just as shown in the





Granite Rock Faced Block, Size 24 x 8 x 8 in., weight 70 lbs.

Smooth Faced Granite Block direct from mold.

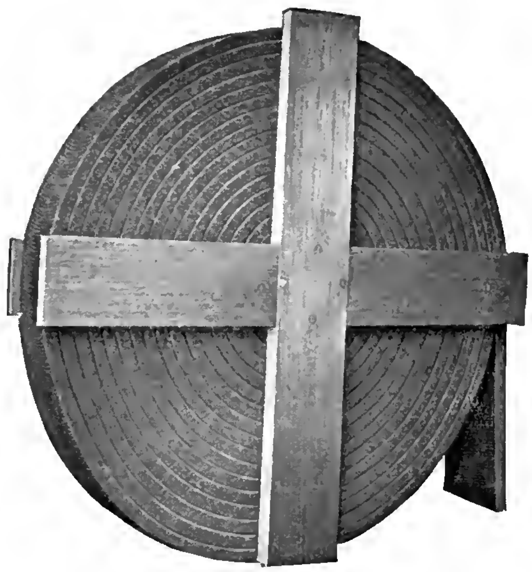
illustrations. The purpose of the glue is to hold the crystals in place and protect one side of them from cement while the block is being cast. The glue all comes away with the face plates in granular form. This method of producing building block is claimed to be a decided improvement over the dry process, in that the product is more beautiful in appearance, has greater strength, is impervious to moisture, and costs less.

Activated Sludge Defined

The best definition of the activated -sludge process of sewage treatment which he has ever seen, said T. Chalkley Hatton, chief engineer of the Milwaukee Sewerage Commission, in a paper read before the Indiana Engineers' Society on February 3, is the one given by William R. Copeland, chief chemist for the Milwaukee Sewerage Commission, and is as follows: "The sludge embodied in sewage and consisting of suspended organic solids, including those of a colloidal nature, when agitated with air for a sufficient period, assumes a flocculent appearance very similar to small pieces of sponge. Aerobic and facultative aerobic bacteria gather in these flocculi in immense numbers—from 12,000,000 to 14,000,000 per c.c.—some having been strained from the sewage and others developed by natural growth. Among the latter are species which possess the power to decompose organic matter, especially of an albuminoid or nitrogenous nature, setting the nitrogen free; and others, absorbing this nitrogen, convert it into nitrites and nitrates. These biological processes require time, air and favorable environment, such as suitable temperature, food supply and sufficient agitation to distribute them throughout all parts of the sewage." The activated -sludge process, Mr. Hatton points out, should not be confused with the kind of artificial aeration of sewage, attempted from time to time in the past, which made no use of the sludge, as an aid to oxidation. The new process, Mr. Hatton states, "preserves the aerobic bacteria by keeping the sludge, which is their natural food, in intimate contact with air at all times and keeps them supplied with fresh food from the raw sewage, throughout the whole body of which they are in intimate contact."

A New Expansion Joint

A new material for the expansion joints of concrete, brick or block pavements is now being offered by The Barrett Company. It is a mastic which comes ready to lay, in ribbon form, in a variety of widths and thicknesses. It contains no felt or paper reinforcement. A new process known as the "Fibre Weld" process gives to the bituminous mastic the requisite cohesiveness to stand handling and storage in the ribbon form, without affecting the elasticity that is necessary for expansion requirements. It seems to



Barrett's New Fibre-Weld-Process Expansion Joint.

possess all the elasticity of a poured bituminous joint with all the advantages of easy handling. The material is waterproof and weatherproof and is not injured by street acids or automobile oils. It does not become brittle with age or cold weather and does not soften or run in hot weather. Its chief advantage over the usual poured bituminous joint is the elimination of heating or pouring apparatus and a great reduction of the labor item—as it takes only a moment to unroll the joint and cut and put it in place. It will be marketed under the name of "Barrett's Expansion Joint."

London-Port Stanley Electrification

Former Steam Road Being Successfully Operated by Electricity — Description of Main Features

After several months of operation by electricity the London & Port Stanley railway system appears to be fully justifying the hopes of the promoters of this scheme and gives promise of working out so successfully from an engineering and financial standpoint that the dream of a network of hydro radials, covering the whole of the province of Ontario, may now begin, with good reason, to take definite shape. Though, as yet, a separate unit in itself and as such, it is believed, able to show a balance of profit over operating and fixed charges, there is no doubt that this road would find its greatest usefulness as the nucleus of a larger system of radiating lines, which would act as feeders and distributers throughout considerable areas in south-western Ontario. Indeed it is the expressed policy of the engineers of the Hydro-electric Power Commission of Ontario that in seeking to standardize their equipments and system of operation they had prominently in mind the conditions that would have to be met in the years to come when Hydro radials shall be as common as Hydro transmission lines are today. For this reason practice that would naturally have been followed on a 25 mile line as a separate unit has, in many cases, been departed from, and plans substituted having in view a network of possibly ten times that amount of road in the near future.

The essential difference between the London & Port Stanley electrification and that of the earlier systems in Canada which have been considered the standard up to the present time is that the operating voltage is 1,500 d.c. instead of 600. This change of course has demanded higher factors of safety at every point and the variations in design have been worked out and undertaken largely on this account. It is of particular interest to note that the increased voltage, as such, is causing no greater operating difficulties than were experienced with the lower voltages.

Though this road is spoken of in general as an electrification of a steam line, it is, in effect, a new road from the bottom up. For many years the line has been leased to various steam railway companies and when it reverted to its owners, the city of London, in 1914, and it was decided to electrify, it was found necessary to overhaul the roadway from one end of the line to the other. To this end the old 56 pound rails were replaced by 80 pound standard steel, ties were replaced by new untreated cedar and the track was reballasted throughout. Fortunately the bridges were found, for the most part, to be in good condition but a considerable amount of concrete curbing had to be built along various parts of the line.

The Rolling Stock

Up to the present time the rolling stock acquired consists of three 60 ton electric locomotives, five 61 foot steel motor cars, three 61 foot trailers and one 61 foot express car with motor equipment. This latter car is well adapted to give a rapid delivery of farm produce into St. Thomas and London. Further equipment includes five 36 foot steam road box cars, four 36 foot steam road flat cars and three 34 foot steam road cabooses.

The specifications of the various cars are also given below in detail.

The locomotives are of the type 404 G. E. and are carried on two swivel trucks, bringing all the weight on the drivers. Equipment is housed in steel box type cab extending over practically the entire length of the locomotive. Each locomotive is provided with four G. E. 251, 750/1500 volt motors, designed for 750 volts across each armature but insulated for 1,500 volts. Two motors are connected permanently in series and the two motor groups thus formed are capable of connection in series or parallel for speed control as desired.

The cab is divided into three compartments, one at each end for accommodating the operator, with an intervening compartment to house the control equipment and accessories. 1,500 v. electric radiators are used for heating.

Each of the motors has an hourly rating of 254 h.p. with 1,500 volts on the trolley. At this rating the locomotives exert a tractive effort of 21,500 pounds. Control is by double-end Type M. standard equipment, a master controller at each operating position actuating the main 1,500 volt contactors by means of a 600 volt circuit supplied from a dynamotor. Multiple-unit train operation is arranged for so that the simultaneous control of all three locomotives coupled together can be accomplished from any master controller. The equipment is designed that the locomotive may haul a train of passenger trailer cars and provide illumination for them.

Current is collected by pantograph slider trolleys having two contact pans pressing against the trolley conductor. Both ends of the locomotives are provided with pantographs. The pantographs are electro-pneumatically controlled from any operating position with 1, 2 or 3 locomotives hauling a train. The pantograph equipments on the motor-cars and express car are identical with those on the locomotives.

Express Car

Body—Length of body, 59 ft. 6 in.; length over-all, 61 ft.; width over-all, 9 ft. 2¾ in.; height from top of rail to top of trolley board, 13 ft.; truck base, 40 ft.

Truck—Type, National Steel Car Co.; wheel base, 7 ft.; diam. of wheel, 36 in.; tread of wheel, 4 11-32 in.; type of wheel, steel tread; size of journal, 5 in. by 9 in.; diam. of axle, 6 in.

Fig. 1.—Standard steel pole carrying trolley, feed and signal system wires.

Electrical equipment—Motors, type G. E., 225 B. 750 1,500 V.; motors, 4-125 h.p.; control system, Sprague, type M.; controller, hand control; gear, number of teeth, 57; pinion, solid teeth, 21; type of air compressor, G. E., C. P., 27-A.; size of air compressor, 35 ft.; size of brake cylinder, 14 in.; type of governor, M. L., Form A., G. E. Co.; type of car heater, 1,500 volt Consolidated Car Heater Co.; type of pantograph, G. E. slider trolley; type of pilot, steam locomotive type; type of snow scraper, H. E. P. Comm.; type of headlight, U. S. Incandescent; type of hand-brake, Peacock.

General—Weight of body, 32,000 lbs.; weight of trucks

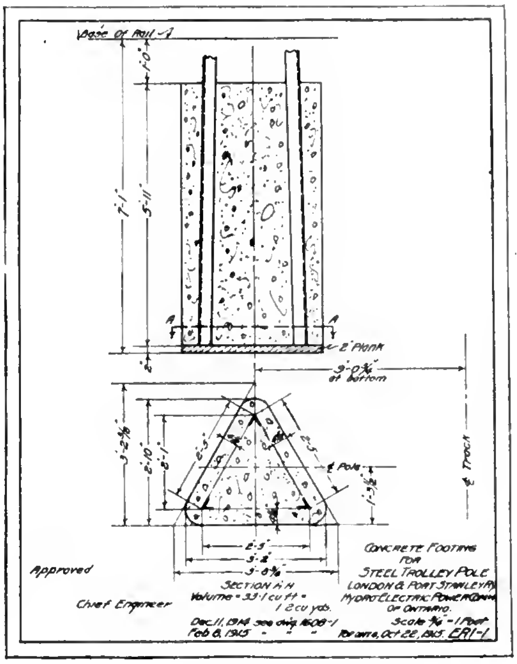


Fig. 2.—Standard steel pole footing

with wheels and axles only, 21,800 lbs.; weight of electric and air-brake equipment, 28,000 lbs.; total weight of car complete, 81,800 lbs.

Motor Cars

Body—Length of body, 59 ft. 6 in.; length over-all, 61 ft.; width over-all, 9 ft. 6 in.; height from top of rail to top of trolley board, 13 ft. 5¼ in.; seating capacity, 56; truck base, 34 ft. 4 in.

Truck—Type, Baldwin Locomotive Co., M. C. B.; wheel base, 7 ft.; diameter of wheel, 36 in.; tread of wheel, 4 11-32 in.; type of wheel, steel tread, M. C. B.; size of journal, 5 in. by 9 in.; diam. of axle, 6 in.

Electrical equipment—Motors, type G. E. 225 B, 750/1,500 V.; motors, 4-125 h.p.; Control system, Sprague, Type M.; controller, hand control; gear, number of teeth, 57; pinion, solid teeth, 21; type of air compressor, G. E., C. P., 27 A; size of air compressor, 35 ft.; size of brake cylinder, 14 in.; type of governor, M. L., Form A., G. E. Co.; type of car heater, 1,500 volt Consolidated Car Heater Co.; type of pantograph, G. E. slider trolley; type of car seats, Heywood Bro. & Wakefield Co.; type of pilot, steam locomotive; type of snow scraper, H. E. P. Comm. design; type of headlight, U. S. Incandescent; type of hand brake, Peacock.

General—Weight of body, 40,000 lbs.; weight of trucks with wheels and axles only, 24,000 lbs.; weight of electric and air brake equipment, 28,000 lbs.; total weight of car complete, 94,800 lbs.

Trailer Cars

Body—Length of body, 59 ft. 6 in.; length over-all, 61 ft.; width over-all, 9 ft. 6 in.; height from top of rail to top of trolley board, 13 ft. 5¼ in.; seating capacity, 60; truck base, 34 ft. 6 in.

Truck—Type, National Steel Car Company; wheel base, 6 ft.; diam. of wheel, 34 in.; tread of wheel, 4 11-32 in.; type of wheel, cast iron; size of journal, 5 in. by 9 in.; diam. of axle, 5⅜in.

Equipment—Control system, Sprague, type M; controller, hand control; size of brake cylinder, 14 in.; type of car seats, Preston Car & Coach Co.; type of pilot, steam locomotive; type of snow scraper, H. E. P. Comm. design; type of headlight, U. S. Incandescent; type of hand brake, Peacock.

General—Weight of body, 40,000 lbs.; weight of trucks with wheels and axles only, 20,000 lbs.; weight of electric and air-brake equipment, 2,661 lbs.; total weight of car complete, 62,661 lbs.

Locomotives

Body—Length of body, 28 ft.; length over-all, 37 ft. 4 in.; width over-all, 9 ft. 7¼ in.; height from top of rail to top of trolley board, 12 ft. 10⅛ in.; truck base, 17 ft. 6 in.

Truck—Type, G. E., M. C. B.; wheel base, 7 ft. 2 in.; diam. of wheel, 36 in.; tread of wheel, 4 11-32 in.; type of wheel, solid steel; size of journal, 5½ x 10; diam. of axle, 7 in.

Electrical equipment—Motors, type G. E. 251 R 750/1500 V.; motors h.p. 250; control system, Type M, multiple unit; controller, type C. 107 A; gear, number of teeth, 70; pinion, solid teeth, 16; type of air compressor, 2-C. P. 30; size of air compressor, 35 C. F. per M.; size of brake cylinder, 16x12; type of governor, G. K. 3; type of car heater, 1,500 v. Consolidated Car Heater Co.; type of pantograph, slider trolley; type of pilot, G. E. design; type of

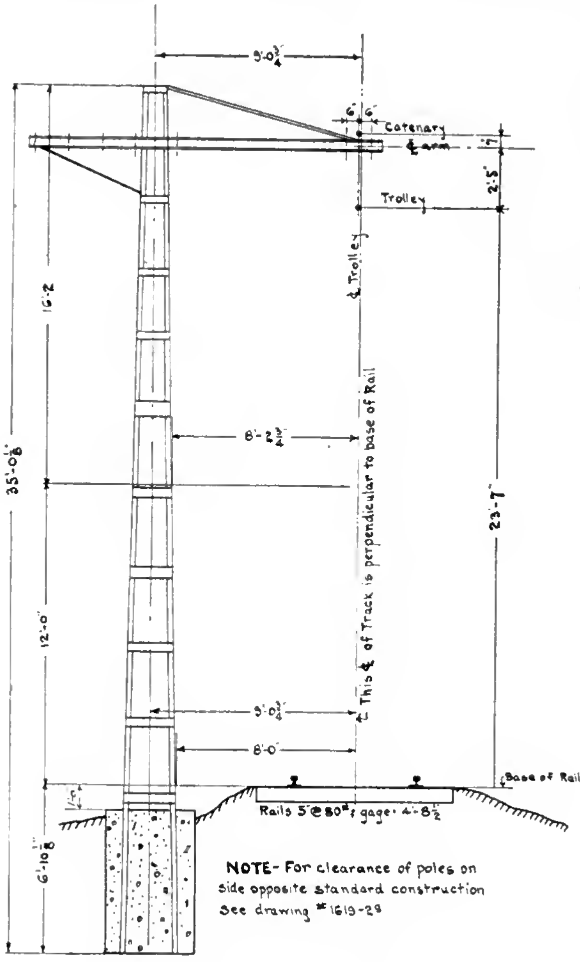

Fig. 3.—Standard steel pole.

headlight, U. S. Incandescent; type of hand brake, rachet and drop lever type.

General—Weight of electrical equipment, 38,950 lbs.; total weight of car complete, 120,000 lbs.

Car Construction

The passenger car is built of steel, with wood trim; the entire bottom is structural steel, diagonally braced; the end and vestibule framing has special provision against the destructive effects of collision; corner posts and side posts are of channel construction; side sheathing and roof, steel plate; inside trim of car is solid mahogany inlaid in quarter-cut finish; the vestibule is finished in steel with ash trim with the exception of the doors and windows, which are mahogany. Each vestibule has two drop windows, a 26-in. end door, and two 29-in. side swinging doors.

The interior finish is green, with plush seats of high-back design in the main compartment, and pantasote imitation leather, high-backed seats for the smoking compartment. Solid bronze metal trimmings are used in the main compartments. The toilet rooms are of white sheet steel with white enamel and white steel fittings. The exterior finish of the car is black.

At each end of the car is placed a steam locomotive type iron pilot, on the top of which is a steel plate snow plow controlled by levers from the operating platform.

Lighting and Heating Circuits for Cars

The voltage for the lighting and heating circuits is cut down from 1,500 to 600 volts d. c. by means of a dynamotor. The lighting arrangement consists of five three-cluster semi-indirect ceiling fixtures in the main compartment, one light in each cluster being in series with the corresponding light in the next cluster; also there is a sixth three-cluster semi-indirect ceiling light near the toilet room with its three lights in series with the two lights in the toilet rooms. The baggage room and vestibule lighting consists of two series circuits of five lights each, these circuits being controlled by two three-way switches, one in the baggage room, the other in the vestibule. All lights are controlled from a switchboard in the baggage room. All circuits are 600 volts d.c., grounded, with five lights in series.

Fig. 4.—Special design trolley wire hanger.

The car is heated by means of thirty-six electric heaters, placed on the walls, two in the vestibule, one in each toilet, twenty-eight in the main compartments, and four in the baggage room. The heaters are connected in two circuits of 18 each in series, and are supplied from the switchboard in the baggage room.

Lighting Arrangement in Passenger Cars

One of the figures shows the complete wiring diagram of the passenger cars. The lighting arrangement consists of six three-lamp semi-indirect ceiling clusters in the main compartments, five lights in the baggage room, four lights in the toilet rooms, and three lights in the vestibule. The lighting arrangement is to operate five 120-volt lamps in series on the 600-volt service. To obtain this number one lamp in each of the first five main clusters is connected in series with the corresponding lamp in the next cluster. This makes three complete circuits, but if any one of the circuits becomes dead only one lamp in each cluster goes out. The three lamps in the sixth cluster are all in series, together with two lights in the toilets. For the vestibule and baggage room lights a unique scheme has been worked out whereby the motorman may light the vestibule or the baggage room at his convenience for the accommodation of passengers entering or leaving the car. By means of two three-way switches, one in the vestibule and the other in the baggage room, the motorman can, from whichever end he happens to be operating from, turn out the lights in that end without interfering with the lights at the other end, and can, during stops, illuminate both ends.

Control System

The system of control is the non-automatic type M, two-speed multiple unit, arranged to operate the motors in series and series parallel. The two pairs of motors, with their resistances, are all in series on the first point of the controller, the resistances being varied through the first nine points on the controller and short-circuited on the tenth or running point. An electro-pneumatic operated change-over switch is used to make the transition between series and series parallel. Either pair of motors may be cut out by means of a separate handle on this switch. The control system is so arranged that at least six motor cars can be operated as a unit from either end of any car.

The Pantograph

The current collectors are the sliding pantograph type of trolley, two pantographs per motor car. These pantographs are pneumatically raised and automatically lower themselves when the pressure is released. Each pantograph can be raised or lowered from any operating position in either the motor or trailer car. Each is provided with a cut-out plug to render it inoperative without interfering with the other pantographs. The design of the pantograph is practically standard, with the exception that the legs extend downward through the common hinge. This construction permits of a greater vertical range.

The Source of Supply

The supply of electric energy is taken from the lines of the Hydro-electric Power Commission of Ontario at London and St. Thomas. At these two points arrangements were made for housing the converting equipment in sub-stations already built, so that no new sub-stations were required for the railway system. In London the equipment was installed in one of the sub-stations of the local hydro commission and in St. Thomas space was available in the high tension station of the Ontario Commission. In each of these two stations two 500 kw. rotary converters 13,200 a.c. to 1,500 d c. were installed. Feed wires are 500,000 c.m. aluminium.

The Overhead Line

The overhead work is carried on triangular steel poles which are utilized for the combined purpose of supporting the feed wires, the trolley wire and the wires of the dispatching system. A pole drawing with cross-arm and showing relative location of the various circuits is shown herewith. Specifications of poles are as follows:—Weight, 800 lbs.; material, galvanized structural steel angles; height, 35 feet; base, concrete, 7 feet in depth, one foot exposed above surface, Fig. 2, cross arms, 4 in. channel; height of cross-arm, 26 ft. above rail; distance apart of poles, 140 to 180 ft.; strain test at top of poles, 2,500 lbs. In yards wooden poles are used with span wires, the standard spacing being 90 feet.

Anchoring and Sectionalization

The details of the overhead are shown for the most part in the accompanying line drawings and photographs. The line is anchored every three-quarters of a mile by steel poles One of these is placed on the other side of the track opposite a standard pole and connected by anchored wire to the next adjoining standard pole.

The trolley and the supply system are sectionalized about every four miles; the sectionalization arrangement is as indicated in one of the illustrations herewith.

Contact System and Type of Suspension

On all main line work catenary suspension is used. The catenary wire is 300,000 c.m. copper, and the trolley is 4/0 grooved. A special design for the trolley wire suspension was developed by the Commission for this contract. A clip with a lip, see figure, fits into a groove on each side of the trolley wire, and is clamped into place and suspended by a hanger to the catenary. These suspension clips are placed every 20 ft. on the main line. In yards, where the poles are most closely spaced, direct suspension is employed as shown.

Rail Bonding

Bonds are of 4/0 copper, welded to the outer side of the rail heads. The oxy-acetylene process was used. In practice, the bonds together with a tank each of oxygen and acetylene gas were carried on a light hand car, the whole outfit being operated by one man. Both rails are bonded.

Operating records of such equipment and apparatus are

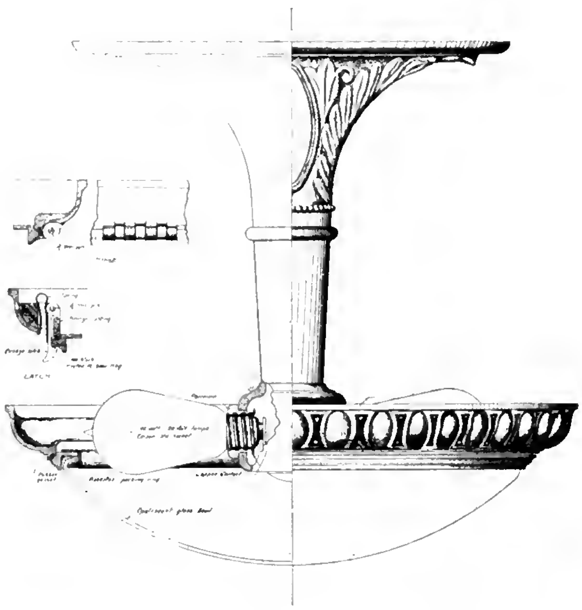

Fig. 5. Type of semi-indirect unit used on passenger cars.

interesting, and it might be pointed out that during the last five months since this road was placed in operation, interruptions to service have been negligible.

New Books

Irrigation Practice and Engineering—by B. A. Etcheverry, head of the Department of Irrigation, University of California. McGraw-Hill Book Company, Inc., New York, publishers; price $4 net. This is Volume III. of a series of text-books, of which the two latter volumes are devoted to a presentation of the fundamental principles and problems of irrigation engineering. The present volume is devoted particularly to irrigation structures and distribution systems. Illustrated by twenty plates and 186 figures; 438 pages; bound in the usual type of this publishing house; approximately 9 by 6 inches.

The Western Canada Lime Company, Limited, has been incorporated with a capital of $100,000 and head office at New Westminster, B.C.

Personal

Mr. Jules Alexander Duchastel, B.A.Sc., the new president of the Canadian and International Roads Congress, is engineer for the city of Outremont, P.Q. He took a leading part in the recent congress, reading a paper, and speaking on several subjects. Mr. Duchastel, who comes from an old French family, graduated in 1901 at Laval University. For a short time he was with the Phoenix Bridge and Iron Works, and then for five years was on the engineering staff of the C. P. R., construction of bridges and elevators de-

Mr. J. Duchastel, Mem. Can. Soc. C. E.

partment. In 1907 he was appointed engineer for the town of Outremont, then a comparatively small suburb of Montreal. Under Mr. Duchastel's supervision extensive works have been laid out, including a new sewage system, a lighting system and road programme. Last year Outremont obtained a city charter; it is one of the finest outlying districts of Montreal, with a beautiful park, wide streets, and splendid residences.

Mr. K. H. Smith, of the Nova Scotia Water Power Commission, delivered an address on "Some engineering features of the Pan-Pacific International Exposition, with particular reference to the lighting arrangements and the Canadian exhibit," before the Nova Scotia Society of Engineers at their regular monthly meeting held at the Technical College, Halifax, on March 15. The lecture was illustrated by a large number of slides specially prepared for the purpose.

Mr. Hugh Watkins, of London, England, who is the quantity surveyor for the Manitoba Parliament Buildings, and in this capacity is required in Winnipeg to arrange and prepare the quantities for the tenderers, tried recently to leave for Canada, but was forbidden to do so by the military authorities, being eligible for military service. The Hon. T. H. Johnson, however, wrote to Acting High Commissioner Perley in London, asking him to assist Mr. Watkins in getting away, and has now received word that the matter has been satisfactorily arranged. Mr. Watkins will bring with him designs for a dome drawn by S. Bylander, an English engineer.

Obituary

Mr. W. L. McGiverin, vice-president of Dartnell, Limited, builders supplies, Montreal, died suddently on March 17, at his residence, Regent Avenue, Montreal, aged 40. He was operated on a short time prior to his death for varicose veins; the operation was apparently successful, but he became suddenly ill, and died within a day or two of taking to his bed. Mr. McGiverin, who served in the Boer war, was a native of Toronto.

Mr. C. H. Conery, who carried on a cement and contracting business in Guelph for many years, died on March 10.

Mr. Charles Sellers, head of the Peerless Furniture Company, Toronto, died suddenly on March 20, at the age of 83. Mr. Sellers was born in Glasgow, Scotland, and came to Canada when about eighteen years of age.

Mainly Constructional

East and West—From Coast to Coast

Machineries, Limited, Montreal, have been incorporated.

Rochefort & Normand, plasterers, Montreal, Que., have registered.

The Deakin Construction Company, Quebec, Que., have registered.

V. Marcotte & Cie, bricklayers, Montreal, Que., have registered.

Dussault & Verrall, contractors, Montreal, Que., have registered.

Theodule Lessard & Fils, general contractors, Montreal, Que., have registered.

The Renfrew Machinery Company, Limited, Renfrew, Ont., were burned out recently; loss insured.

There are indications of considerable building activity in Amherst, N. S., during the spring and summer.

The Ottawa Board of Control at a recent meeting decided to advertise for a Commissioner of Works.

It is reported that the Bell Telephone Company will erect a new exchange building in Barrie this summer.

The Dominion Salvage & Wrecking Company, Limited, has been organized, with head office in Toronto and a capital of $25,000.

Canadian Welding Works, Limited, is the name of a newly-incorporated concern with head office at Montreal and a capital stock of $10,000.

Ice conditions at Port Arthur seem favorable to an early opening of navigation. Grain in the elevators at the head of the lakes totals approximately 35,000,000 bushels.

The Dominion Bridge Company have been awarded the contract for the steel work for the T. Eaton Company new building at Winnipeg. The cost of the steel alone is estimated at $200,000. The building will be 200 feet long by 123 feet deep and eight storeys high.

The first steps are now being taken towards rebuilding the Northern Navigation wharf at Sarnia, Ont. A steam pile driver will start at once to drive the piles which will support the structure. Owing to the great depth of water at this point, long piles are required for the work.

Leading dealers in building supplies in Saskatoon, Sask., report having been called on for more estimates in the last three months than in all the year of 1915. The demand is very considerable from the farming communities, where many good buildings will be erected this season.

Montreal will have to pay a considerably higher price for its asphalt this year. The tender of the Warner-Quinlan Asphalt Company for 6,000 tons at $19.33 per ton has been accepted by the Board of Control. This is nearly $5 per ton above that of last year, when the contract was the subject of much legislation. The bids ranged from $19.33 to $32.40 per ton.

Under the patronage of Their Royal Highnesses the Duke and Duchess of Connaught, the Ottawa Chapter of Architects, during the week beginning March 27th, will hold an exhibition of architectural drawings, paintings, sculpture, etc. Messrs. Darwin's, Limited, have placed at the disposal of the Association the shop at No. 43 Sparks Street, in the Union Bank Building. The proceeds will be devoted to patriotic purposes.

That German prisoners of war confined to Fort Henry were employed by a Kingston contractor at the rate of 75 cents a day to do work inside the walls of the fort was a matter which came up for discussion at a meeting of the Trades and Labor Council of Kingston, Ont. The contractor claimed that the men were employed because no other labor was available. The Trades Council declared that there were sufficient local men available. The members of the Council have been given assurance that these prisoners will not be employed again.

The Conley Frog and Switch Company, of Memphis, Tenn., have agreed to have complete and in operation by July 31 the plant which they started between Port Arthur and Fort William in 1913, and which they were unable to carry on because of the financial conditions created by the war. They will manufacture frogs, switches, bolts, nuts, and all railway accessories, and will employ at least fifty men. They have agreed to expend $100,000 on the works, and the city of Port Arthur is to allow them a bonus of $25,000 when the plant has been in operation for thirty days.

The full pamphlet copy of the annual report of the Bethlehem Steel Corporation for 1915—the first full year of the war—is just being issued. A summary of the chief feature of the report, made public recently, shows the total net earnings, from operations of the corporation and its subsidiary companies, after deducting expenditures for ordinary and extraordinary repairs and maintenance—"approximately $4,391,000"—amounted to $24,821,408.25, compared with $9,649,667.71 in 1914. The orders on hand on December 31, 1915, amounted to $175,432,895, against $46,513,189 on the corresponding date in 1914.

The Roman Catholic School Commissioners of Montreal, having awarded a contract to Mr. Joseph Laurier for the construction of a school at a price of $176,700, Mr. F. A. Grothe asked Mr. Justice Dugas, in the Practice Court, for an interlocutory injunction, to prevent the execution of the contract. The contention was that Mr. Grothe, being the lowest bidder, ought to have secured the contract, and that there was nothing in the plea of the Commissioners that Mr. Grothe was not a resident of the city. The Commissioners, it was stated, had given the contract to the successful bidder on condition that he executed the work at the price asked by the petitioner. The judge dismissed the petition on the ground that the Commissioners were not bound to accept the lowest tender.

The Ontario Government, in making good its pledge to develop actively the resources in Northern Ontario, has spent in the last three years close on three million dollars. Up to the end of the provincial year of 1914 the province had expended $2,076,833, while last year the expenditure totalled $689,910, of which $582,914 was spent on road construction. Commissioner Whitson reports that 597 miles of new road were cut out of the virgin forest during the year, 281 miles of new and old roads were graded and surfaced with gravel or stone, and 113 miles of old roads were partly graded or improved. In all 872 miles of road were under construction. In addition to this a dam was built 450 feet in length, across the Frederickhouse River to improve navigation on Night Hawk Lake and tributary streams.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Berlin, Ont.
The City Council will receive tenders until April 13th for the construction of about 6,000 square yards of concrete pavement. Engineer, H. Johnston.

Chatham, Ont.
Work will start as soon as weather permits on the construction of reinforced concrete pavement on King Street East and Lansdowne Avenue. Approximate total cost, $13,360. Engineer, F. P. Adams.

Collingwood, Ont.
Tenders will be received until 8 p.m., April 11th, for the following:—(1) pumping machinery, consisting of two motor-driven units, with a capacity of 1,000 Imperial gallons each; (2) pump well and connections. Engineers, Chipman & Power, Mail Building, Toronto.

East Farnham, Que.
The Secretary to the Village Council, M. Stevens, will receive tenders until noon, April 15th, for the gravelling of the main road through the Municipality.

Halifax, N.S.
The Mayor, P. F. Martin, will receive tenders until April 5th for the supply of 5,000 feet of cast iron pipe. Specifications with City Engineer.

Lethbridge, Alta.
The City Council are considering the installation of a filtration plant. Engineer, A. M. Grace.

London, Ont.
Tenders are now being received for the construction of about 60,000 square yards of asphalt pavement. Engineer, H. A. Brazier.

Moncton, N.B.
The City Engineer, J. Edington, has been instructed to prepare specifications and to obtain estimates on the following kinds of pavement:—creosoted pine block on concrete foundation; bitulithic on concrete; asphalt on concrete.

Quebec, Que.
Tenders will be received until April 4th by the Waterworks Engineer for the following supplies:—pig lead, lead pipe, cast iron pipe, iron and brass castings, cement, brick, drain pipe.

Toronto, Ont.
A by-law has been passed authorizing the construction of a foot subway under the Grand Trunk Railway at Ashdale Avenue. Commissioner of Works, R. C. Harris.

The Board of Control will receive tenders until April 11th for electrically operated driving gear for a 36-inch gate valve at the Main Pumping Station. Plans at Room 12, City Hall.

Commissioner of Works, R. C. Harris, has recommended the following works:—cement sidewalks, $1,587; rocmac macadam pavements, $22,835; asphalt pavements, $5,320.

CONTRACTS AWARDED

Wallaceburg, Ont.
The Town Council have let the contract for the supply of water service equipment to Mueller Bros. Company, Sarnia.

Railroads, Bridges and Wharves

Alberta Province
A delegation has urged the Government to complete the projected portion of the Canadian Northern Railway between Medicine Hat and Hanna.

CONTRACTS AWARDED

Edmonton, Alta.
The Edmonton, Dunvegan & British Columbia Railway have awarded contracts to McPherson & Quigly, 119 Adams Block, for the construction of a bridge over Burnt River and for the piers and abutments for the bridge to be built over Smokey River.

Public Buildings, Churches and Schools

Brampton, Ont.
The Town Council have passed a grant of $18,000 to the School Board for the erection of a four-roomed school. Secretary to the Board, John D. Gordon.

Dalroy, Alta.
Tenders on the construction of a frame school for School District No. 2690 will be received until noon, April 5th, by the Secretary, F. W. Gardner.

Harcourt Township, Ont.
The Trustees of School Section No. 1 will call for tenders about May 1st for the erection of a school. Estimated cost, $9,000.

Hespeler, Ont.
The Roman Catholic Congregation propose to build a new church as soon as possible, at an approximate cost of $10,000. Priest, Rev. Father Meyer.

Mimico, Ont.
Victoria Industrial School Board have approved plans for a school, estimated to cost $4,000. Work will be done by day labor and material purchased by Superintendent C. Ferrier. Steel and brick construction.

Montreal, Que.
The Protestant Board of School Commissioners, Belmont Street, are receiving tenders on the erection of a brick school on De Jumonville Street. Closing date, April 3rd.

North Vancouver, B.C.
The School Board propose to build an addition at the North Lonsdale School, estimated to cost $3,500.

Parry Sound, Ont.
The Board of Education have appointed Angus & Angus, of North Bay, as Architects for the proposed school.

Raleigh & Tilbury, Ont.
Charles Tompkins, Merlin P. O., will receive tenders until April 8th for the erection of a school for Union School Section No. 2. Architects, Adams & Adams, Market Chambers, Chatham. Approximate cost, $4,000.

St. Julienne, Que.
Tenders on interior work and the installation of furniture and fixtures at the Parish Church are being received by the Architect, J. O. Turgeon, 55 St. Francois Xavier Street, Montreal.

Tavistock, Ont.
The School Trustees propose to build an addition to the school, at an approximate cost of $5,000. Architect, J. S. Russell, 21 Downie Street, Stratford.

York County, Ont.
The ratepayers of School Section No. 14 are considering the erection of a school, at an approximate cost of $6,000. Secretary, F. J. Mulholland, Eglinton R. R.

CONTRACTS AWARDED

Cayuga, Ont.
The general contract for the erection of an addition to the school has been let to William Rolston. Brick construction. Approximate cost, $7,000.

Fort William, Ont.
The contract for installation of heating and plumbing at St. Luke's Church has been let to Anderson & Company, Donald Street.

Hamilton, Ont.
The Board of Education have awarded the following contracts for the erection of an addition to the Robert Land School:—masonry, G. F. Webb, Wentworth Street, $13,829; carpentry, John Poag, 685 Main Street E., $6,469; steel, Hamilton Bridge Works, Bay Street N., $4,750; roofing, M. V. McLean, 314 Hess Street; plastering, Hill Bros., 307 Emerald Street; painting, William Dodson, 121 Victoria Avenue N.; plumbing, Adam Clark, 7 Main Street W., electrical work, Electric Supply Company, 65 James Street South.

Montreal, Que.
The Cote des Nieges Roman Catholic School Commissioners have let the following contracts for the erection of a school and residence:—general, masonry, wrought iron, carpentry, plastering, painting and glazing, E. N. & U. Boileau, 312 Fabre Street; steel, Phoenix Bridge

& Iron Works, Limited, 83 Colborne Street; roofing, plumbing and electrical work, Thomas O'Connell, 183 Ottawa Street; steam heating and ventilating, T. Lessard & Sons, Limited, 191 Craig Street East.

Ottawa, Ont.
In connection with alterations to the County Jail, the contract for electrical work has been let to Stanley Lewis, Richmond Street, Westboro.

Rimouski, Que.
The contract for interior work at the Chapel has been awarded to A. M. Morin, Trois Pistoles. Architect, P. Levesque, 115 St. John Street, Quebec. Approximate cost, $5,000.

St. Julienne, Que.
The contract for plumbing at the Parish Church has been awarded to Hickey & Aubut, 93 Dominion Street, Montreal.

Woodhouse, Ont.

CONTRACTS AWARDED

Davin, Sask.
The Davin Rural Telephone Company have awarded the contract for the construction of their system to Brander & McGuay, Regina, at $8,890. Contractors require material.

Fires

Albert, N.B.
Residence of Frank Geldart totally destroyed.

Bromptonville, Que.
Factory of the Model Dress Company. Loss, $25,000.

Residence of O. Lambert entirely destroyed.

City View, Ont.
Residence of John Daoust, Raden Avenue. Loss, $3,500. May rebuild.

Residence of S. Cousineau, Raden Avenue. Loss, $4,000. May rebuild.

Glencoe, Ont.
Store owned by C. Dean, Main Street. Loss, about $10,000.

London, Ont.
Work shop at Asylum on Dundas Street, owned by Provincial Department of Health. Loss, $5,000. Will be rebuilt.

Moncton, N.B.
Store owned by Duncan Brace, Railway Avenue, totally destroyed.

Montreal, Que.
Factory of the Canadian Rubber Company. Loss, $50,000.

Quebec, Que.
Bowling alley owned by L. A. Cannon, 2 Ferland Street. Loss, $10,000.

Raymond, Alta.
Cafe and store owned by Charles MacCarty totally destroyed.

Regina, Sask.
Roundhouse of the Canadian Northern Railway, Toronto. Loss, about $15,000.

St. George, Ont.
Agricultural plant owned by B. Bell & Sons. Loss, $10,000.

St. John's, Que.
Furniture factory of D. H. Langlois & Company. Loss, $16,000. Will rebuild.

Miscellaneous

Cottam, Ont.
J. A. Jackson, contractor, is in the market for cement, weather strips, lumber, wood paint, asphalt shingles and screens.

Hurdville, Ont.
James Hardie is in the market for three saw edger and portable sawmill machinery, as well as a 40-h.p. boiler.

Kingston, Ont.
The City Engineer, R. J. McLelland, will receive tenders until 5 p.m., April 3rd, for the supply of 300 tons, more or less, of refined asphalt, f.o.b. Kingston.

Ottawa, Ont.
Tenders will be received until April 3rd by William Kearns, 110 Wellington Street, for hardware, lumber, cement and sand required by the Ottawa Improvement Commission.

Quebec, Que.
The City Engineer, W. D. Baillairge, will receive tenders until April 5th for the supply of broken and unbroken stone, sand, deals and nails.

St. Thomas, Ont.
Horton Brothers are receiving prices on brick, sheet glass, skylights and ventilators.

Westmount, Que.
Tenders will be received until noon, April 5th, by the City Secretary, A. F. Bell, on the supply of the following materials:—cement, sand, crushed stone, sewer pipe, quarried stone, farm tiles, brick. Engineer, P. E. Jarman.

CONTRACTS AWARDED

London, Ont.
The City Council have let the following contracts for supplies:—iron castings, Owl Manufacturing Company, Ltd., 351 Glebe Street; gravel and screenings, G. Alexander, 516 Piccadilly Street; cement, W. Buchanan, Bank of Toronto Building; vitrified tile, William Copp, 93 York Street.

Montreal, Que.
The City Council have awarded the contract for the supply of 6,000 tons of refined asphalt to the Warner-Quinlan Asphalt Company, 745 St. Catherine St. W., at $19.33 per ton.

Ottawa, Ont.
The City Council are having plans prepared for laying creosoted wood block and asphalt pavement on Dalhousie St. Tenders will be called early in April. Estimated cost, $12,000. Engineer, F. C. Askwith.

Late News Items

Huberdeau, Que.
The hotel owned by O. Duclos has been totally destroyed by fire. Loss, $25,000. Owner will rebuild.

Leamington, Ont.
The Town Council have let the contract for laying concrete pavements on Mill and Erie Streets to F. Smithson, care of the Town Clerk, R. M. Selkirk. Approximate cost, $15,000.

London, Ont.
A. E. Nutter, Dominion Bank Chambers, is preparing plans for two residences, estimated to cost $8,000 and $6,000 respectively.

Montreal, Que.
Alexander McKay, 498 Argyle Street, is building a block of flats on Addington Street and another on Minto Street, estimated to cost $15,000 each. Contracts will be let for marble and tiling work.

Napanee, Ont.
The Town Clerk, W. A. Grange, will receive tenders until April 3rd for supply of the following materials during the year:—pine plank, nails, stone, broken stone, rubble, gravel, cement and sewer tile.

Ottawa, Ont.
In connection with the erection of an addition to an office building for Blackburn Bros., Union Bank Building, the contract for steel work has been let to the Dominion Bridge Company, Sparks Street. Tenders on painting, heating, plumbing and electrical work will be called by the Architect, W. E. Noffke, Plaza Building, Rideau Street.

Port Colborne, Ont.
Tenders on the erection of St. James Church will be received until 6 p.m., April 15th, by the Secretary, E. P. Johnson, or the Architect, C. M. Borter, Main Street, Niagara Falls South. Approximate cost, $15,000.

Regina, Sask.
The City Council have awarded the contract for supply and installation of an electrically driven pumping plant at Bogg Creek to Fraser and Chalmers of Canada, Limited, 59 Beaver Hall Hill, Montreal. Approximate cost, $12,000.

St. Andre D'Acton, Que.
The contract for concrete work required in the construction of a bridge for the Municipal Council has been awarded to Grise & Houle, St. Christine, Que., and the steel work and flooring to the Dominion Bridge Company, 145 St. James Street, Montreal.

Three Rivers, Que.
In connection with the factory which is being built at St. Roche and St. Marqueret Streets for the City Council, the contract for heating, plumbing and electrical work has been awarded to N. Dechene, 106a Desforges Street, at $13,000.

Whitby, Ont.
Robert Hutchison, Public School Inspector, will receive tenders until April 15th, for the erection of a residence, estimated to cost $6,000. Architects, Barber & Tilley, Temple Building, Brantford.

An Agreeable Surprise

THE business men of Toronto have been agreeably surprised by the action of their city council in appointing Mr. Thomas Bradshaw as head of their finance department. The surprise is intensified by the facts that Mr. Bradshaw did not seek the position, is not a politician, was not even the subject of a largely signed electors' petition or delegation and, finally, is well suited by training, experience and ability for the work.

The salary naturally was some considerable bone of contention among certain of the aldermen but even on this point there was surprisingly little hesitation. The chances are that Mr. Bradshaw will save his salary many times over to the city each year. We have only to recall a comparatively recent sale of City of Toronto bonds where the price obtained was too small, it was charged, by somewhere between a quarter and a half a million dollars. The employment of novices in work of this sort is not true economy.

The only possible objection that the appointment of Mr. Bradshaw seems to be open to is that heads of some of the other departments will immediately begin to pull wires and get their machinery oiled for agitation to even salaries up. They will forget that Mr. Bradshaw is being paid this amount because he is worth that much to the city. They will forget, some of them, that they are already paid all, and much more than all, they are worth to the city. We hope the Toronto city council, having done a really commendable act and shown good judgment, will continue in the way of discriminating between men who are capably holding their positions and those who are just capably holding on.

The City Beautiful

SYSTEMATIC organization by municipal authorities of a spring "clean-up" campaign is being more widely extended each year. The movement has received valuable assistance by the information gathered and published by the New York State Conference of mayors and city officials in their report on Municipal Clean-Up Campaigns, extracts from which are printed in this issue. "Clean-up" week has in recent years become increasingly popular as a means of beautifying the city and in stimulating civic pride in the cleanliness and safety of the home and the development of public affairs. Upwards of three thousand cities in the United States and Canada take an active interest in a "clean-up" week, and the methods employed by the different cities are many and varied. The value of the press cannot be overestimated as a factor in the clean-up movement. By means of announcements, editorials, cartoons, advertisements, etc., it can probably interest a larger number of people than any other agency. Insurance companies and civic improvement organizations do a great deal by their co-operation in the movement for sanitary laws and conditions.

Clean-up time generally comes some time during April or early in May, and in most cities extends over a period of two weeks, with a regular programme for each day of that period. The mayor of the city or town usually appoints a clean-up week committee who adopt some plan of action and appoint sub-committees and divide the work among district organizations. Publicity is then given to the campaign through newspaper bulletins, circulars, posters, moving pictures, private advertising, etc. Motion pictures are a valuable medium of bringing before school-children and citizens the ravages of the fly and actual conditions existing from unsanitary conditions. One of the greatest factors in a clean-up campaign, to make it a success, is the co-operation of the school-children. One of the best means of reaching the adults is through the children, and the education of the children themselves along these lines will contribute materially to their sense of proper community conditions when they grow up. Lectures on home and community gardens and the benefits to be derived from a cleaner and more beautiful city, with prizes for the best-kept yard, aid very considerably in furthering the campaign.

The good effects of clean-up week have been so universally recognized that some cities have crystallized the movement into an ordinance, making it unlawful to deposit within the city limits rubbish of any description. A tour through any city after "clean-up week" would convince the most incredulous that in promoting this movement municipalities have materially lessened their fire risk and improved their sanitary conditions. Some of the good results conceded to a "clean-up" campaign are—improvement of housing conditions, reduction of fire loss, elimination of unsightly lots, stimulation of civic pride, and the development of the community spirit in a movement for improved public welfare.

Change of Name

The Regina branch of the Canadian Society of Civil Engineers, recently organized, are considering the advisability of changing their name to the "Saskatchewan Branch" so that it may be more apparent that all members of the engineering profession in that province are members of the C. S. C. E. and included in the organization. The following letter is being sent out to Society Members throughout the province by the secretary of the Regina branch and is self-explanatory:

Dear Sir:—Only a few months ago the Members of the Canadian Society of Civil Engineers residing in Regina and its vicinity followed the example of nearly all eastern cities and most of our western centres in forming a branch of our Parent Society here. During its short existence, it has proved a valuable medium of professional intercourse, giving an opportunity of meeting representatives of our profession in its many different branches of work.

While it is true that we all belong to one Society, yet the considerable distance which separates the members residing in Saskatchewan from the headquarters at Montreal prohibits a very active and personal interest being taken by them in the affairs of the Society and therefore decreases considerably the service and usefulness of our Society. In order to overcome this difficulty and to give our members living in this Province a centre for periodical meetings for the exchange of their views on various professional subjects and eventually perhaps for the formation of a small provincial Library, etc.—it is the intention to follow the example of the Branch at Winnipeg and to extend our scope, so as to include all members residing in Saskatchewan. We propose therefore with the support of a majority of those members to change our name into "Saskatchewan Branch."

The undersigned Secretary therefore would thank you to advise him as soon as possible of your views on the subject.

Sgd. J. H. deStein,
Secr.-Treasurer Regina Br.

Make Specifications Clear

Recently the Montreal Catholic School Commissioners rejected a tender for the erection of a school on the ground that the person tendering was not a citizen or ratepayer of Montreal. The Montreal Builders' Exchange has taken up this matter and in a letter addressed to the Commissioners point out that the advertisement calling for tenders contained no stipulation of any kind; consequently it was expected all tenders would be considered and adjudged on their merits. "My board, however," says Mr. D. K. Trotter, the secretary of the Exchange, "were surprised to learn that at the meeting at which tenders were opened the question was raised whether certain of the tenderers were or were not citizens and ratepayers of the city of Montreal. I have been instructed to suggest that in future advertisements calling for tenders, your board should specify clearly and definitely the class of contractors whose tenders will be accepted. Should your board, however, persist in the method I have referred to the Builders' Exchange is advised that this will tend to discourage reputable firms from tendering on future work, and thus deprive your board of some of the benefits to be derived from competitive sealed tenders. You, of course, are well aware that when any general contractor submits a tender to your board, money and time have been consumed in its preparation, and there is no apparent reason why this work should be done without an opportunity being afforded of having its merits tested alongside its competitors." The Exchange asks that in future advertisements the Commissioners should define more specifically the conditions on which tenders will be considered and accepted.

Toronto Harbor Work

It is understood that the Toronto Harbor Commission will spend $700,000 in connection with this summer's work. The work started by the Government in Ashbridge's Bay and the Humber Bay will be completed, and in addition the transformation of the old harbor and water-front will be proceeded with. An order-in-council has been passed at Ottawa establishing a permanent headline in the Toronto harbor between Bathurst Street and a point opposite Yonge Street.

The plans provide for the establishment of seventeen acres of industrial area at the foot of Bathurst Street, which will be served by 800 feet of dock and 20 feet of water. There will also be modern freight sheds and factory buildings. In connection with the extension of the pier-head and bulkhead line, the C. P. R. and G. T. R. have waived their riparian rights to water lots between Bathurst and John Streets, and will join the Commission in application to the Government for approval of the new lines.

Edmonton Branch C. S. C. E.

Through the courtesy of the National Electric Light Association of New York City, the Edmonton Branch of the Canadian Society of Civil Engineers had the opportunity of showing a series of lantern views of the Panama Pacific Exposition at their regular meeting on Friday evening, March 24th. These views showed very clearly the wonderful lighting effects secured by the Engineers in charge of the illuminations at the Exposition. The chair was occupied by Mr. G. H. V. Bulyea, Chairman of the Public Utilities Commission for Alberta. The Lecturer for the evening was Dr. J. A. Allan, of the University of Alberta, who spent Some four weeks at the Exposition.

Toronto Branch C. S. C. E.

The regular monthly meeting of the Toronto Branch of the Canadian Society of Civil Engineers will be held in the Chemistry and Mining Building of the University of Toronto on Thursday, April 13th, 1916. Professor A. P. Coleman, Ph.D., will give an illustrated address on "A Visit to the Mountains of Northern Labrador."

Shall I Build Now, or Wait? Comparative Prices Today and at Outbreak of War

Does it cost more to build to-day than it did at the outbreak of war? This is the question repeatedly and persistently asked almost daily of the contractor, the architect and the manufacturer. Is the price of materials higher? Is labor dearer? Shall I build now or wait?

This is, in reality, a more complex problem than may appear on the surface and the answer is not easily found. One of the biggest difficulties is that conditions vary greatly with different buildings. Plainly, much will depend on the type of construction. For example, a building in which brick bulks large will benefit more by the low price of that material than one to be constructed chiefly of stone or steel. The most apparent fact of the whole situation is that the variation in the prices of the things that go to make a building has not been uniform. This will probably mean a readjustment of plans in many cases. Quite often, no doubt, it will be found that certain material, which ordinarily would be specified, has increased in price correspondingly more than another material that will serve the purpose almost equally well. This might lead to a re-planning of the whole structure. It is evident then that instead of the owner planning his building to-day on the basis of a couple of years ago he will do well to consider the trend of prices in the meantime and so determine whether some other type of construction formerly more expensive may not now have become more economical.

The subject of varying prices in building materials looms up so prominently on the construction horizon to-day, and the question is raised so frequently, that it has occurred to us that possibly a more or less comprehensive review of the price situation, as it affects the different elements of the building trade, might prove of interest and value to our readers. With this in mind we have been endeavoring to collect, from many sources, during the past few weeks, comparative figures and prices now and, say, a year ago or at the outbreak of the war. These figures we are now placing at the disposal of our readers in the hope that they may prove helpful. The quantity of material collected makes it almost necessary that we should spread it out over more than one issue. This week we are dealing more particularly with what may be considered the coarser construction materials and, generally speaking, those which represent the largest percentage of the cost of building, namely: stone, brick, cement and lime and sand. In following issues it is our purpose to deal with other more or less closely associated groups.

Stone

The price of building stone and sand is practically the same as it was in 1913—if anything a little easier—and quarry owners report that unless the labor situation becomes more acute they do not look for any immediate advance in prices. The cost of imported stone has been increased by the extra war tax, which amounts to three cents per cubic foot, but this is apparently offset by the keener competition which is the result of the slowing up in building operations. It is a peculiar fact that the price of stone has remained practically the same during the last decade, no doubt due to the improved machinery and equipment for quarrying which, to a large extent, offsets the increased labor cost. Crushed stone also stands today at the same price as at August 1, 1914. Approximately a year ago lower prices, from 10 to 15 per cent., were quoted for crushed stone but it has recently been found necessary to re-establish the former prices. Rubble stone has been unchanged throughout.

Brick

Without doubt, of the larger industries, brick has been hit harder by the war than any other building industry. The manager of one of the largest brick works in Canada writes us that their "prices to-day are fully twenty-five per cent. less than prices received previous to the outbreak of the war." Another manager writes us of a case where brick is being delivered on the job about two miles from the brickyard at $7.50 per thousand. This is for a kiln run stock of brick that would have cost at least $9.50 in 1913 and from $10.50 to $12.00 in 1911. It will thus be seen that prices on common brick are away below what they have sold at for several years. The price of face brick is probably about $2.00 less than at the outbreak of war.

It must be understood that these are conditions apparently brought about by many of the works being over-stocked when war broke out and that present prices result from their determination to keep their businesses going at almost any cost. With any considerable increase in building it is believed that prices are due for an advance anywhere up to 20 per cent. As there is unmistakable evidence of much greater building activity this year than in 1915 the advice of one manufacturer to prospective buyers "buy their material at once if at all, otherwise they will be unable to take advantage of the prevailing low prices" would seem to be sound and worth heeding.

Cement

The price of cement has varied from constant to about ten cents lower. One western Ontario firm places the reduction at 15 cents a barrel since the war broke out. It is pointed out, however, that the demand has been less than half of normal and that this reduction will not likely hold as soon as the demand increases. So far as cement is concerned there are many reasons why building should go forward this year. In the use of concrete in buildings or elsewhere a large percentage of the men on the job are unskilled laboring men who, at the present time, need work and are willing to work at the same or even reduced wages. This is probably more true in the province of Quebec than elsewhere. This means that concrete construction can be carried out at a lower price than was possible during 1913, 1914 or 1915. In no case have we been quoted an increased price for cement, though it is frequently pointed out that all indications are that prices of building materials will advance owing to a possible scarcity of labor, increased demand for buildings, and the uncertainty of the price of coal.

Lime

Lime also has stood at exactly the same price for the last two years. One dealer quotes us 38 cents per hundred pounds on August 1, 1914, March 1, 1915, and March 1, 1916. Neither in bulk or in the hydrate form has there been any increase in price whatever.

It is evident, therefore, that so far as these four items are concerned building may be carried on during the present year, providing today's prices are maintained, at a cost may be 10 to 20 per cent. less than last year or the year before. The importance of the figures discussed above will of course depend on the percentage of the total cost of the building which these four items represent which, as already pointed out, will vary greatly with the type of building to be erected. There is evidently no change in price in immediate prospect, with the probability, in case of any change at all, that prices will increase.

The Engineer in Peace and War — The Increasing Value of Trained Men

At a sacred and patriotic concert, organized by the Ottawa branch of the Canadian Society of Civil Engineers, held in the Dominion Theatre, on March 26, Mr. Walter J. Francis, of Montreal, read a paper on "The Engineer and the War." After a reference to the relation of the engineer to the normal conditions of the present day life, Mr. Francis alluded to the part Sir P. Girouard played in the Soudan and South African wars. Col. H. S. Greenwood and Mr. A. F. Stewart, both of the C. N. R., also took a leading part in the Boer war. He proceeded:

"The Right Honourable David Lloyd George, the Minister of Munitions, in a speech delivered last summer is reported to have said that the present war is a terrific contest between engineers of the warring nations. The object lesson so tragically taught by Germany has aroused the other nations of the world to a keen appreciation of the result of the application of engineering energy to military purposes. While Germany was, as we all think, so misapplying a great part of her engineering talent, the other nations had been devoting their efforts to the development of the arts of peace. We have been forced to meet the exigencies of the situation, and to our military engineers and to the engineers in civil life has fallen the task of overtaking Germany's forty years of preparation not only on the fields of battle, but in the workshops at home. Two of the most eminent military engineers of the world are in foremost places—Lord Kitchener and General Joffre.

A Cold, Calculated Programme

"The war is an immense work of cold, calculated programme. Let us draw an analogy. A building contractor, let us say, determines to carry out a piece of work in a certain time. He calls his superintendent and explains what is to be done and when it is to be finished. The superintendent in turn calls his foremen and the various interests to whom he looks for co-operation and assistance. The materials are ordered. The laborers and artisans start their work—and the work is completed according to the wishes of the master mind. It is all a matter of mature forethought and cold calculation. There is nothing of accident or haphazard trust-to-luck haste. It is all carefully thought out ahead. The proceedings in the war are quite analogous, only on a stupendous scale. Nothing happens by chance. The constant care is to be in readiness at the necessary or appointed time. I would not modify my analogy but would point out that Germany stands in the position of a contractor with an organization complete and ready, while the Allies have to be likened to one who may be without any organization and have to build it up. Thank the Lord, King Albert and the Belgian engineers and the engineers of France and the British Navy were partly prepared, or we should not have the privilege of discussing the subject this evening.

Lt.-Col. Charles H. Mitchell, G.S.O.

"There was one at least of the Canadian engineers who specially prepared himself in his spare hours for the service of his country in time of need, and I hold in my hand a card received from him not long since. He is a close friend of a number before me and an acquaintance of very many not only in Canada but in Europe—I refer to Lt.-Colonel Charles H. Mitchell, General Staff Officer in charge of the Intelligence Department of the Canadian Army Corps in France. It happens to be a card of felicitation, and he starts out "All goes well at this end." Later he proceeds, "The nice feature about my work is that after all it's pretty much the same in its type as consulting engineering—in fact is the same if you substitute the Huns for the forces of nature." Colonel Mitchell's reference is, of course, thoroughly well understood to many of you, but for the uninitiated let me explain that there is a definition of engineering which describes the engineer as one who deals with the forces of power in nature. Colonel Mitchell finds that the process of handling is the same, only instead of dealing with water powers and all the rest of it his problems are with the enemy. In a letter just received he says, "It is strange and yet very fortunate what an analogy there is between this work and my own professional work at home. The general character of the work, hours, life and thought is similar, the assistants similar and one's activities are quite the same—office work, reports, analysis, correspondence, direction of investigations, deductions, maps, outside tours of inspection, constant telephone activity—all the same if you substitute the enemy for the forces of nature. There is a difference, though. It is seven days a week from 9 a.m. until 11 p.m." The Colonel goes on "Our headquarters are in the Hotel de Ville of this little city (about 12,000 people normally) and it is really quiet and peaceful if one gets used to the passing to and fro of thousands of men and hundreds of motor lorries, motor cars, wagons, and so on, in the day, and the recent aeroplane activity by the enemy, in which he has been dropping bombs on various parts of the town, railway station, flying aerodrome locality, and not forgetting the cemetery. I had the misfortune last Sunday to lose one of my best draughtsmen, killed on the street on his way to a noonday meal." All this is a specific up-to-the-minute statement from an intimate friend at the front, who went to the front at the start, won the Distinguished Conduct Medal at Langemarck and has since been decorated with the Legion of Honour of France.

Railway and Forestry Corps

"Canada is to be congratulated on the special services required of her soldiers. Like Sir Percival Girouard, Colonel Ramsay of the C. P. R., has been called to the front with a corps of railway constructors, every man a specialist in a particular branch of railway construction. He has since been followed by a second corps, and now other engineering parties are being called for to render special services at the front. One of the most unique of these parties is one armed with broad-axes and recently inspected by His Royal Highness in this city. In Flanders we can see them performing their task fearlessly and faithfully. Under the fire of the enemy they unflinchingly construct their bridges and prepare their highways. With tireless energy they minister to the needs and convenience of the men in the trenches. Anywhere, everywhere, their services are required and the special skill stands them in good stead, for it must be remembered that in these bodies of men are artisans of all classes. Let me quote you some of the classes required by the engineer corps now being recruited by Captain Charlebois: bricklayers, carpenters, draughtsmen, mechanics, masons, wheelrights, shoemakers, clerks, drivers, chauffeurs, saddlers, plumbers and tailors. In this connection you will doubtless have noted the similarity between these organizations and the work of the engineer in private life. To every engineer there are many assistants all the way through the various grades to ordinary labor.

"The Canadian Society of Civil Engineers, of which the Ottawa branch is such an important part, has nearly five hundred of its members on the field of honor, and some have made the supreme sacrifice. We all congratulate the Ottawa branch on the fact that it is taking a systematic military engineering course.

The Struggle at Home

"This reference naturally leads me to the fact that the whole of the struggle is not on the battle fields nor indeed in Europe. Soldiers must not be without ammunition. At the outbreak of the war nobody in Canada knew how to make ammunition on a commercial scale. Metal manufacturing industries were paralyzed by the interruption of normal conditions. The Allies needed shells. The Canadian manufacturers in a body rose to the occasion and transformed the shops of the Dominion into shell factories. The speed with which this transformation was accomplished probably stands without a parallel in the history of manufacturing. The Government appointed as the head of a commission an engineer whose knowledge of the machine shops of Canada had been gained from a lifetime in the work following his father and in a few months the shops of Canada had learned their lesson and were exporting shells to the Allies. In recognition of his services Alexander Bertram was knighted by His Majesty King George at the New Year.

"The celerity with which new methods, new processes and accurate measurements were put into practice is a standing monument to the skill of Canadian manufacturing engineers. Let me by a few figures illustrate the transformation which has taken place in one shop alone. Prior to the war this engineering firm employed about twelve hundred men and had a daily output valued at about $30,000. To-day the employees number five thousand men and the value of the daily output is $200,000. It is a significant fact that the President of the Canadian Society of Civil Engineers, as well as two of the immediate Past-Presidents, are all directly or indirectly engaged in the manufacture of ammunition.

The Future

"Naturally from the present conditions in Canada we pass to the thought of the future. When the war is over and when German militarism will have been crushed, what of Canada? Already a new word has been coined in the United States, 'preparedness.' President Wilson recently said 'there may come a time when I cannot preserve both the honor and the peace of the United States,' and the outcome of this movement has been the appointment of a consulting board of specially chosen engineers, composed principally of the representatives from the five foremost engineering institutions of the United States, the American Society of Civil Engineers, the American Society of Mechanical Engineers, American Institute of Electrical Engineers, American Institute of Mining Engineers, and the American Chemical Society. Its immediate work will be to make an inventory of the facts necessary to be known to the army and navy relating to the resources of the nation for the supply of munitions of war in case of need. The French Republic has organized a similar civilian board and has raised it to the dignity of a ministry, 'Le Ministere des Inventions.' Great Britain has also enlisted the services of civilian scientists and technologists with a view to the development of the utmost of the nations' industries for the prosecution of the war.

"Meanwhile the world struggle is becoming fiercer. The engineers in civil life must attend to the production and the transportation. The mines must be kept producing the raw materials, and the factories the finished products. The railways and the steamships and the motor cars must take them to the front, where the military engineers amidst the inferno of shell and machine gun fire are doing their part under the old motto of the Royal Engineers? 'Ubique,' 'Everywhere,' and continuing the fight led by the stirring war cry, 'Quo fas et gloria ducunt,' 'Where right and glory lead.'"

The Toronto and York Highway Commission's Specifications for Road Tars

The specifications given herewith are those used by the Toronto and York Highway Commission, and have been prepared by Mr. E. A. James, of James, Loudon & Hertzberg, chief engineer of the Commission.

For a number of years tar products have been used by the York Highway Commission, and these specifications represent what is considered by Mr. James the products best suited for urban and suburban road work.

The light tars may be used as dust preventives where there is a predominance of iron tired traffic.

The medium tars are well suited for blanket covering of water-bound macadam roads where there is heavy rubber tired traffic.

The heavy tars are suitable for bituminous-bound macadam roads by either the penetration or the mixed method.

Specifications for Coal Tar Cement for Road Purposes

The following specifications cover the requirements of the Toronto & York Highway Commission for 1916 delivery.

The tar products required by the York Highway Commission will fall into three general grades:—

(I.) Light Tars.
(II.) Medium Tars.
(III.) Heavy Tars.

Material

(1) The tar cement shall be a residue of the distillation of coal tars only, and shall be refined for the special purpose of making a paving cement.

(2) No mixture of hard pitch with the lighter oils of coal tar will be permitted.

(3) It shall be uniform in its grade as to its physical characteristics and chemical composition.

(4) It shall not contain over 0.5 per cent. of water soluble materials.

(5) The product shall be free from water as determined by distillation.

(6) The product shall show complete ignition in more than 0.5 per cent. of inorganic matter.

I. Light Tars

The specific gravity shall not be less than 1.10 nor more than 1.20 at 60 degs. F. The viscosity tested by the standard Engler viscosimeter shall not be more than 250 sec. or less than 100 sec. for 100 c.c. at 104 degs. F. On distilling 100 grams of the material to 337 degs. F. not more than 10 per cent. shall distill over. On containing the distillation to 600 degs. F. the residue shall not be less than 65 grams. This residue shall be a soft pitch at 60 degs. F. If the residue appears hard it shall be tested for melting point and the melting point shall not exceed 140 degs. F. by the ½ inch cube method in water. The specific gravity of the entire distillate shall be not less than 1.01 at 60 degs. F. The free carbon shall be not less than 4 per cent. nor more than 12 per cent.

II. Medium Tars

The specific gravity shall be not less than 1.18 or more than 1.28 at 60 degs. F. The viscosity tested by the standard Engler viscosimeter shall be not less than 125 sec nor more than 200 sec. for 100 c.c. at 212 degs. F. On distilling 100 grams of the material, no distillate shall come over below 328 degs. F. On continuing the distillation to 600 degs. F. not more than 25 per cent. of distillate shall come over. The specific gravity of the entire distillate shall not be less than 1.03 at 60 degs. F. The residue from the foregoing distillation shall have a melting point not greater than 165 degs. F. The free carbon shall be not less than 12 per cent. nor more than 24 per cent.

III. Heavy Tars

The specific gravity shall not be less than 1.22 or more than 1.30 at 60 degs. F. The material shall have a melting point, determined by the ½ inch cube method in water of not less than 100 degs. F. nor more than 110 degs. F. On distilling 100 grams of the material, no distillate shall come over below 338 degs. F. On continuing the distillation to 600 degs. F. not more than 15 per cent. of distillate shall come over and the specific gravity of the entire distillate shall be not less than 1.03 at 60 degs. F. The residue from the foregoing distillation shall have a melting point not greater than 165 degs. F. The free carbon shall be not less than 12 per cent. nor more than 25 per cent.

Delivery

The material will be delivered by the manufacturer, freight prepaid at any siding in York County at a price per Imperial gallon (railway weights not accepted). Measurement to be made when tar has a temperature of 77 degs. F.

Payment

Eighty per cent., thirty days after delivery. The balance sixty days after delivery upon the estimate of the engineer. In all cases payment will be withheld until a certificate has been presented showing the grade of the material and that it is according to specifications. If the material is according to said specifications said certificate will be supplied within the payment dates.

The Deterioration of Creosoted Wood Block Pavements

The following article is based on a paper presented before the American Society of Municipal Improvements at a recent convention in Dayton, Ohio. The paper contains a collection of data gathered from an extensive investigation of existing wood block pavements.

Heretofore, discussion of wood-paving block specifications have been largely theoretical. These discussions have dealt with the relative advantages or disadvantages of straight coal-tar creosote, additions of refined coal tar to creosote, water-gas tars, etc.—theories unsupported by experience and clouded by a general lack of knowledge as to what the various terms meant; even at the Dayton convention there was a difference of opinion as to just how to define commercial creosote.

Actual Experience With Creosote Preservatives

A study of European specifications for wood-preserving oils has likewise shown wide variation in requirements, but at the same time uniformly satisfactory results. All these specifications, however, distinctly require that the oil shall be a coal-tar creosote derived from strictly pure coal tar. European experience has further shown that any good creosote derived from pure coal tar injected in proper quantities into sound seasoned timber protects the timber from decay for 25 or more years. The particular percentage of naphthalene, tar acids, etc., appears to have very little to do with results.

The results of examinations clearly show that in the majority of cases—practically universally—failures and defects in streets paved with creosoted yellow-pine blocks could be attributed to improper laying, poor foundations, omission of expansion joints, want of proper drainage, etc. Failures caused by decay of the blocks were far less numerous, and such failures were usually in comparatively old pavements.

Very thorough examinations were made of two wood-paved streets in St. Louis, Mo. In addition to removing many of the decayed blocks a careful examination was made of the sound blocks in the immediate vicinity of those decayed. Oil was extracted from the sound blocks and analyses made, which were compared with the analyses of the oils originally used. On both streets what are usually known as extremely light oils were used; one showed evidences of petroleum adulteration.

The causes of failure in these blocks are laid to one or more of the following: (1) Insufficient amount of oil; (2) poor penetration, particularly of the sapwood; (3) use of oil containing petroleum compounds instead of one of strictly coal-tar origin; (4) insufficient absorption due to high water content in the sapwood; (5) use of a very light naphthalene-containing oil, a large percentage of which had evaporated from the blocks.

None of the blocks treated with a straight coal-tar oil showed decay in any of the sapwood which still contained the preservative, which could not be said of the blocks treated with the oil containing petroleum.

Similar examinations were made of streets in Toledo, Ohio, which served to indicate even more strongly than those in St. Louis that the two factors—poor quality of oil (that containing petroleum additions) and insufficient penetration—had in all probability caused the failures. The failure of blocks in a pavement in Charleston, S. C., was traced to the use of a straight water-gas oil and very poorly penetrated blocks. Efficient penetration depends on the condition of the timber—its water content and soundness; on the character of the wood treated; on the volume of oil injected; to a slight degree on the character of the oil used—that is, the percentage of insoluble matter; and on the temperature employed during the treating process.

In treating paving blocks the absorption and penetration are determined by two factors—(1) The individual characteristic of the piece of wood to be treated, that is, the natural density and the percentage of water contained in the individual stick, and (2) the volume of the oil injected.

The densest piece absorbs the least quantity of oil, the most porous piece the highest quantity, when both are treated in the same charge under the same conditions. Pieces with high water content absorb less oil than those with low water content. A charge into which an average of 20 lb. per cu. ft. of creosote is injected shows better penetration than one in which only 10 lb. per cu. ft. is injected.

In order to determine the law of penetration for paving blocks, a number of experiments were made, using both a solution of coal tar and creosote oil and a straight creosote oil. Five different tests were conducted, each at a different treating plant. In each case 100 paving blocks, picked at random, were carefully weighed individually before treatment. Each block was carefully numbered for identification.

These 100 blocks were treated in a regular charge, and immediately after the treatment the blocks were weighed again, to determine the amount of oil absorbed. The results of these five tests were plotted on diagrams. There were two diagrams for each test, one set showing the variation in absorption in the 100 blocks, without relation to the weight of the individual blocks before treatment. At the bottom of the diagram two scales were given, the lower one showing the number of ounces absorbed, the upper showing the number of pounds per cubic foot. Individual crosses were used to show the number of paving blocks which absorbed the quantity of oil indicated by the figures at top and bottom.

A study of these charts shows that no matter what kind of oil was used, no matter at what plant the blocks were treated and irrespective of the condition of the timber at the time of treatment, there was a small number of blocks in each case which absorbed a comparatively small quantity of oil. Similarly a small number of blocks absorbed a comparatively large quantity of oil, and between these two there were various degrees of absorption; but the largest number of blocks invariably fell near the point which gives the intended average absorption.

The other set of charts shows the relation between the weight of individual blocks and the amount of oil absorbed per cubic foot in those blocks. These charts also show that irrespective of the kind of oil used or the kind of timber, there is a definite relationship between the weight before treatment and the amount of oil absorbed. The denser and heavier the block the smaller is the quantity of oil which it absorbs. That there is an important relation between the amount of oil absorbed per block and the penetration is of course obvious. Blocks which absorbed only 2 oz. of oil showed a far different penetration from those which absorbed 30 oz.

Conclusions from Accumulated Data

The conclusions drawn from all these experiments and the examinations of actual conditions in the street are that a thorough penetration of every block is impossible, but that a thorough penetration of the sapwood is absolutely essential for the preservation of the block. This can be easily obtained, provided sufficient quantities of oil are used and provided that the process of injection is properly conducted, irrespective of whether a straight creosote distillate oil or a solution of a reasonable amount of coal tar and creosote is used for preservative.

As to bleeding of newly laid wood-block pavements, both the straight creosote and the coal-tar solution stand on identically the same basis, provided the method of treatment is faulty. The criterion to be used in specifying the preservative ought to be only availability and cost. Both creosote oil and creosote oil mixed with coal tar are available and should be used. A reasonable addition of coal tar to creosote is held to be good practice, but a straight coal-tar product free from the admixture of other substances should be specified.

Municipal "Clean-Up" Campaigns

Various Methods and Plans as Employed by U.S. Cities — Organization — Programmes — Benefits Derived

The season of "clean-up" is about due. Systematic spring campaigns have of late become more and more popular and are receiving recognition in all parts of the world. Not only among towns and villages has the idea taken hold, but in some of our largest cities extensive work is undertaken each spring to beautify the streets and parks. Clean-up week is generally set for some time in April or early in May.

In this connection we are just in receipt of a report, "Municipal Clean-up" by the State Bureau of Municipal Information of the New York State Conference of mayors and other city officials. This report describes various methods and plans adopted by U. S. cities for municipal "clean-up" campaigns, their organization, literature used, programmes, etc. As indicating the wide-spread interest among our neighbors to the south in city cleanliness we print the following extracts from this report. Many Canadian towns would, we believe, do well to become more conversant with this subject.

In 1914 more than 2,500 cities and towns in the United States took an active interest in "clean-up week." As many cities use practically the same plans, the Bureau has attempted in this report to give only a resume of the various methods and plans adopted.

That clean-up week does not mean simply clearing the streets and vacant lots of rubbish and waste is shown by the extensive programmes carried out in most of the larger cities: Committees on fly extermination, mosquito extermination, vacant lots, school grounds, parks, back yards, front yards, fences, grass seed, flower seed, plants, railroad yards, manufacturing districts, business districts, alleys, public dumps, garbage, inspection of unsanitary conditions, fire prevention, etc., all enter into the clean-up element. Unsightly abandoned buildings, old houses and factories must be inspected and razed; combustible materials, wooden boxes, paper, furniture, etc., to be collected; chicken yards, stables, and railroad yards with their litter of scrap iron must all come in for their share of attention if the clean-up campaign is to be a success.

Propaganda

At the head of propaganda as well as publicity stand the insurance companies. They reach the individual citizen and endeavor to get his co-operation in the movement for more sanitary laws and conditions. Unlike the press they reach the foreigner, and the class of people who do not read the newspapers, or at best only the Sunday editions. One insurance company, which maintains an extensive welfare department, has ten millions of industrial policyholders in the United States and Canada. A collector,makes a weekly visit to every one of these homes, and at the same time distributes leaflets and circulars disseminating sound ideas in regard to public and private health.

It is not possible to over-rate the value of the press as a factor in the clean-up movement. Its work does not stop with the spreading of information both before and during the campaign, but in some instances has taken part in the activities. Its columns have been open to everything of a news nature that would materially assist—news stories, special articles, editorials, daily programmes, cartoons, advertisements, etc.

While the removal of rubbish is essentially a municipal affair, it would appear that it has been left, in most instances, to civic organizations, chambers of commerce, women's clubs and school clubs to stir up the agitation in regard to the collection of it.

Regular Programmes

Some cities have a regular programme for each day, such as paint day, fire prevention day, front yard, back yard, vacant lot, dandelion day, lawn-making, etc. Although clean-up programmes vary in length from two days to a month, two weeks is the usual length of time, and the following is the two weeks' programme:

Monday and Tuesday (fire prevention days): Induce all merchants, manufacturers and property owners to give special attention to cleaning up accumulations of rubbish out of attics, cellars, hallways, basements and barns. Make a special effort to get rid of all material that will cause fire.

Wednesday and Thursday (repair days): These days should be devoted to repairing porches, porch furniture, lawn swings, sidewalks, fences, screens and screen doors.

Friday and Saturday (paint-up days): These days are set apart for painting porches and porch furniture, doors, windows, screens, etc.

Second Week

Monday and Tuesday (front yard days): Give special attention to beautifying lots. Rake off all rubbish and clean sidewalks and gutters, plant flowers and make concerted effort to get rid of dandelions.

Wednesday and Thursday (back yard days): Clean yards, sow grass and flower seeds, plant trees, general clean-up.

Friday (vacant lot day): This is the day when people living in each neighborhood should help clean up vacant lots.

Saturday (inspection day): This ends the campaign and should be given over to public celebration, parades, inspection, etc. Usually a parade of school children headed by a band, motors carrying the mayor, superintendent of schools and other persons having charge of the campaign.

(The report here deals with the organization of committees by the mayor and the adoption of a plan of action or procedure to be followed by any particular city.)

Publicity

In the Philadelphia campaign the total space devoted to newspaper publicity amounted to 14,225 lines, or 88 full length columns of printed matter, or one column a day for eleven days in each of the daily papers. For the benefit of the foreign born the same information was printed in every foreign newspaper published in that city. Cartoonists depicted "clean-up week" as a family affair and showed it to be a real pleasure as well as a necessity. The editorial writers in a more serious vein urged the necessity of co-operation and pointed the way to communal benefits to follow.

Cincinnati reports that no other factor contributed to much to the success of the campaign as the newspaper. By giving daily reports of the progress of the work during clean-up week the newspapers create a rivalry among the various wards.

(The report publishes here a number of sample bulletins and posters as employed by different cities to excite public interest in their campaigns.)

Circular Letters

Over the signature of the director of the department of public works letters were sent to all advertisers, and every concern known to manufacture, advertise or sell any kind of an article used for cleaning purposes; business men's associations, women's clubs, civic organizations, theatre managers and real estate agents. The purpose of these letters was to request co-operation and secure local publicity. Neighborhood meetings, prize competitions for boys and girls, window displays and local newspaper advertising, were ideas suggested.

Circulars

Four million circulars printed in five languages, five municipal departments co-operating, in the municipal house cleaning in New York City. One official circular reads as follows:

"To every owner, occupant, representative of any building, apartment, room, yard or vacant lot: You are hereby notified to prepare and place within the stoop line for removal all rubbish and waste material, from lots, lofts, fire escapes, cellars, yards, alleys, air shafts, rooms and apartments. Old bedding, rugs, paper, furniture, broken-up boxes and barrels; glassware should be placed in barrels, boxes and bundles. It is against the law to throw materials in the streets. Neglect to comply with this notice will result in prosecution. The wagons will call at 8 A. M. Wednesday, May 20, 1914."

Placards

Placards bearing the silhouette figure of William Penn majestically swinging a broom over the city from his dizzy perch on top of the city hall appeared in every one of Philadelphia's 3,200 trolley cars. These were placed in the front and rear entrances in such a way that only the figure was visible from the outside. The appearance of the black and white sketch minus title or descriptive matter of any kind was perplexing to the passengers on entering the car and they would immediately look at the reverse side for an explanation. They got it in the form of an announcement for the annual "clean-up week," with just enough information and advice to be profitable, and most effective. This same figure was also distributed among the schools, libraries, railroad stations and other prominent places.

300,000 badges and blotters bearing sketches and jingles applicable to Clean-Up week were distributed among the schools.

School children dressed as little White Wings carried banners with the following inscription, in Toledo: Brighten up.

200,000 14 x 16-inch show cards, featuring the figure of William Penn, and below, the four words, "Soap, Water, Paint, Polish."

A large poster, 20 x 30 inches, along the same lines as the show card, was given space by the posting companies in more than 500 places throughout the city.

Street cars, elevated trains and platforms are utilized in an effort to attract the attention of citizens to their duty of cleaning their premises:

1. **Remember the time—April 25.**
2. **Help us clean up Philadelphia.**
3. **Soap—Water—Paint—Polish.**

Small leaflets, with applicable inscriptions, distributed by retail stores on packages.

Motion pictures and lantern slides showing the ravages of the fly, actual conditions existing from dirt, etc., have been a large factor in bringing the necessity for cleanliness before citizens and school children.

Rochester, one of the pioneer cities in the organization of the clean-up movement, arranged its publicity for 1914 thus:

1. The co-operation of the daily press.
2. The exhibition of slides in motion picture houses.
3. Sending letters to all lodges and orders asking for co-operation.
4. Printing by the local railways and light companies on the backs of their bills a fire warning. The same company also displayed similar information on their electric signs.
5. Use of the Boy Scouts to distribute dodgers to householders.
6. The co-operation of the clergy in preaching proper sermons.
7. Co-operation of the real estate exchange in cleaning up and keeping clean all buildings which the exchange have charge of.
8. Inducing manufacturing concerns to print suitable copy on pay envelopes.
9. Sending the fire warning in printed form to cigar stores.
10. Arranged that all caps for milk bottles during clean-up week be printed with a fire warning.
11. Secured the co-operation of all concerns selling fire-proof materials, such as cement, asbestos, fire-proof paint and roofing to advertise heavily during the clean-up week.

Commissioners of public works consented to allow posters put on the back of the rubbish wagons and the commissioner of public safety offered the use of the big fire engines for the same purpose.

Private Advertising

In all the large cities there is much private advertising during the clean-up campaigns: In Philadelphia the regular advertising pages of the newspapers for weeks ran individual advertisements of department stores, calling attention to the reduced prices of articles used for cleaning purposes. The more enterprising managers tried to outrival each other in the amount of space covered.

Special two-page sections contained nothing but advertisements on "clean-up week."

2,648 square inches of space were paid for by private advertisers, counting only single appearances. The majority of the advertisements, however, appeared at least three times, and in many cases daily for a week or longer.

The Metropolitan Insurance Company distributed 150,000 circulars to their policyholders through their agents, who in making their weekly premium calls went into the homes of thousands of foreigners and told them in their own tongue what "clean-up week" meant and why it was necessary for them to do what they were asked to do. This work is handled through the district agents in each city.

Miscellaneous Activities

It is impossible to include in a condensed report of this kind a full record of the help received from every source—by means of personal and telephone communications. No record is kept of such communications. Individuals and organizations all over the country have accomplished great results which have not come to the notice of the public through the newspapers. It is only possible to give here a partial list of the workers and organizations taking important part in these campaigns: The Press, Mothers' Clubs, Women's Clubs, Federation of Women's Clubs, Y. M. C. A., Advertising Clubs, Federation of Churches, Rotary Club, Civic Clubs, City Improvement Associations, Public Schools, Chambers of Commerce, Parochial Schools. All have done their utmost to make their cities more livable. Even the City Officials themselves have not been backward about taking part in the actual work. In the case of one Mayor it was said that anyone calling him on the telephone in the morning during clean-up week would be told that he was out shoveling.

1. The names of 600 owners of unimproved property which required cleaning up were obtained and to each one was sent a written request to remedy conditions. Approximately the entire number replied saying they intended to clean up, and they did so.

2. The city repainted its hydrants and the gas company repainted its street lamp posts.

3. The City Commissioners of Muskogee, Okla., planned to sow Bermuda grass on all vacant lots, and the committee appointed was to canvass all owners of vacant lots, urge them to sow grass and keep it closely cropped.

4. 4,500 tons or 6,136 cubic yards of miscellaneous waste were deposited at the dump during clean-up week in Washington. Not only city dump wagons, but contractors and private teamsters were pressed into service to haul it away.

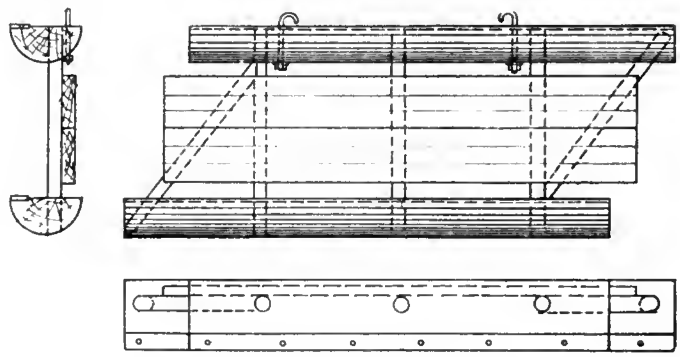
5. Brooklyn, divided into 40 districts, cleaned eight sections a day; local organizations distributed 150,000 pamphlets printed in three languages; the Housewives' League posted 22,000 clean store placards through the city; lectures were given by members of the City Departments which were illustrated by moving pictures and lantern slides.

6. An agitation has been started in Chicago to clean the roofs of the downtown district, as it is claimed that most of the dirt filling the air and streets is blown from the roofs which had not been cleaned since they were put up. The Street Cleaning Bureau is considering the complaint.

An Inexpensive Split Log Drag for Maintaining Country Roads

Any road construction is without permanent value unless a proper system of maintenance is established. An earth road, unless well cared for, is sure to rut and spread because of its soft surface in wet weather. This is especially true in the spring of the year, when the frost is leaving the ground. The surface of the road ruts easily, and unless repaired while still in a soft condition presents added difficulties later on. A systematic use of the split log drag at the proper season is one of the best and easiest methods of efficient maintenance.

The split log drag is easily and quickly made, and should be included in every township's road machinery. A light log from 5 to 7 ft. long, preferably of cedar, pine, or basswood, such as can easily be handled by a team, is split or sawn in halves. Place the halves parallel to one another, somewhat offset, edges down, with the flat face to the front, secure them firmly in this position with three 2-in. oak or elm crossbars, wedged into 2-in. holes bored in each half. These holes should be made somewhat above the centre line to allow the earth being dragged by the rear half to pass under the crossbars. Place two planks about the same length as the log on the crossbars; this enables the operator to stand on the planks and regulate the draft at either end, simply by moving to that end—for instance, if he desires to drag some material out of the ditch and place it in the centre of the road, by moving to the ditch end the draft is increased there, and the other end of the drag sufficiently elevated to allow the earth to pass under. To fill a low spot or a mud-hole, step quickly to the opposite end.



Details of a simple split log drag.

Road maintenance with a steel drag.

The length of the draw-chain also changes the line of draft; lengthening the chain is equivalent to putting a weight on the drag. If the drag is too heavy, shorten the chain; to remove more earth, lengthen the chain. Use some sort of catch clevis so that the drag may be drawn at any desired angle.

The drag may be either built with square ends or with the rear half offset, so that when the drag is drawn at an angle the ends of both halves are parallel with the axis of the road. There are arguments in favor of each design. If the road is soft and the latter type is used the front half takes all the draft, whereas if the halves were square and drawn at an angle each half would take a share of the material being moved.

The use of a strip of steel along the cutting edge not only gives the drag a better cutting edge, but also preserves the face. Fasten a strip of steel 2 x 4 ins. wide and ⅜ in. thick along the lower edge of the drag, and secure with stove bolts or heavy screw nails properly countersunk. Handles on the drag are often a decided advantage.

By dragging this implement up one side of the road and down the other the edges of the log plane off the ridges and rough places, drawing the material sideways and forward, filling in the ruts and hollows, and crowning it at the centre of the road. Use the drag when the road is very wet and slushy, or when very dry. There is an intermediate stage when the earth sticks and rolls up in lumps. If a clay road is dragged in a wet state a tough, rubber-like surface is produced. By means of this drag, together with a plow and harrow, much can be done to create a new road and keep old ones in good repair.

The steel drag is also very extensively used in some parts of the country, and while it may be more efficient for certain types of roads, it is often too heavy for a team of horses, and is not so cheap or easily handled as the split log drag.

Progress Report, Imperial Oil Building, Church Street, Toronto

Exceptionally rapid progress is being made on the new Imperial Oil building, located at the corner of Court and Church Streets, Toronto. Work on the new building commenced on December 8, 1915, when excavations were begun, the foundations being carried down 22 feet below street grade. Steel erection, including all riveting and painting was completed on

Imperial Oil Building, Church and Court Streets, Toronto.

March 31. The contract for the steel was placed on December 10, 1915, and steel was on the site ready for erection in two months' time. The arches were commenced on March 13, and are all in as far as the third floor at the present time. The exterior stone work started on March 25, and will be completed on or about May 10. Plumbers, electricians, and steam fitters are already on the job, and the work is well ahead of schedule.

The building occupies a frontage of 76 feet on Church Street, and extends back 115 feet on Court Street. It is of fireproof construction, steel framework with limestone exterior walls, and is seven storeys high, including the basement. The building was designed by Clinton & Russell, architects, and the contract was let to the Thompson-Starrett Company, of New York.

The exterior of the building will be Bedford limestone, in the Italian Renaissance style. The main entrance is on Court Street, which opens into a large hall leading to the three elevators and tower staircase. The ground floor will be given over for a banking room and stores, and will not at present be partitioned off. All the upper floors will be occupied by the Imperial Oil Company and its subsidiary companies. The rear of the building, adjacent to a 23-ft. driveway on the west side, will be taken up by storage room and display rooms for the products of the company. In the base-

Steel erection, March 21, 1916.

ment provision is made for a gymnasium, a court, shower baths, and locker rooms for the convenience of the occupants of the building.

The interior trim will be most elaborate, the building being finished in marble with marble mosaic floors and steel doors and trim. The board room of the Imperial Oil Company will be finished in panelled mahogany with ornamental plaster ceiling. Contractors are as follows: structural steel, Dominion Bridge Company; masonry and fireproofing, Witchall & Sons; steel casings and trim, A. B. Ormsby; plumbing and heating, W. J. McGuire, Limited; ornamental iron works and bronze, Architectural Bronze and Iron Works; electric wiring, L. K. Comstock Company; hardware, American Hardware Company; elevators, Otis-Fensom Elevator Company; plastering, A. Petrie; marble, Missisquoi Marble Company; vaults, J. & J. Taylor.

Modern Methods of Garbage Collection by Wagons and Motors

FOR collecting garbage in the larger cities of the United States many types of vehicles are used. Most cities are at present using a steel tank wagon, with either a bottom or a rear dump, depending upon the house treatment of garbage and whether the system is combined or separate. To be clean and sanitary any garbage vehicle should be metallic, fitted with covers, easily cleaned and disinfected, and as large as is convenient with the grades and conditions of the route traversed. Particular attention should be paid to the loading height, which should be at a convenient distance from the ground so that the collector can easily dump the garbage.

Type of Cover

The type of cover is also important. The most satisfactory type is the light, ribbed roof, arched over the top of the wagon at sufficient height to give a free space above the whole of the garbage, and to allow trap doors in the side of the wagon for emptying cans. The use of wooden or iron doors is impracticable, because they do not allow for expansion of the load. Wooden covers warp, do not fit tightly, need repairs often, and are in the way during collection. Iron covers are almost universally condemned on account of their weight and noisiness. Most cities use canvas covers.

Whatever the type of vehicle, the dumping arrangement should be quick and simple. The bottom dumping wagons give good results, but they cannot be used for town garbage unless wrapped. Many cities successfully use a rear dump wagon which is tilted by a hand-turning gear at the front.

Motor Truck vs. Wagon

The use of the motor truck for garbage collection has not always excited favorable comment in cities. There are several motor trucks in service in U. S. cities, but practically all of them are used for hauling from transfer stations over long distances to the place of disposal. The general concensus of opinion is that for distances less than a mile horse-drawn vehicles are best, while above that a motor truck is most economical, and that the electrically-driven motors are cheaper to operate than the gasolene-driven where the haul is short and many stops have to be made.

St. Louis recently made computations comparing the existing cost of hauling garbage from the longer haul distances with mule teams and by tractors. The distance was seven miles, and the saving in adopting the motor truck system was $3,500 a year. The Worcester Commission reports that for heavy long hauls under conditions where the truck can be kept moving the motor truck is the more economical. The city of Seattle hauls its garbage by motors from bunkers to place of final disposal and claim that they save from one-fifth to one-quarter of the time consumed by horse-drawn vehicles.

New York's Gas-Electric Trucks

The New York City Department of Street Cleaning recently made a test on motor trucks and proved their efficiency over the present system, giving a possible 18 per cent. for time lost in hauling, loading, and returning light, as against 43 per cent. under the existing system.

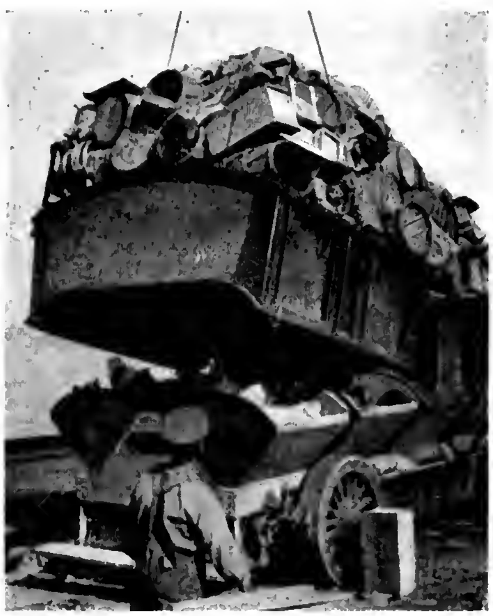
New York garbage collection—One of the 12 gas-electric trucks with trailer.

The twelve motor tractor-and-trailer units now employed in the model street-cleaning district of New York city, under the supervision of Commissioner Fetherston, are designed to do all the work in that district, including the collection of garbage, ashes and paper refuse in the day, the sweeping and flushing of the streets at night, and the cleaning off of snow in winter. Aside from the multifarious work which they are designed to do and the elimination of all horse-drawn vehicles in the area in which they work, the tractors are featured by the use of gas-electric drive and by the fact that they haul huge 20-ton detachable trailers.

Cheapness and Simplicity

The selection of the gas-electric type of drive on the tractors was made for cheapness and operating simplicity. While the electric tractor was highly desirable from the standpoint of ease of operation, the fact that each unit has to work 16 out of the 24 hours every day made its use impossible except by the employment of two sets of batteries, because of the mileage limitations imposed upon it by the storage battery equipment. On the other hand, the gasoline tractor with gear transmission, clutch and spark and throttle controls was impracticable because of the great number of stops in collection work, averaging from 60 to 100 per hour, and the subsequent slow acceleration between stops, the comparatively large consumption of gasoline during these periods, and the resulting necessity for drivers of a higher class.

The gas-electric type of drive, comprising a gasoline motor directly connected to an electric generator whose output is used in motors driving the rear wheels, combines the desirable qualities of both the purely gasoline and the purely electric tractor. The mileage



Unloading at docks by electric hoist.

limitation of the latter is overcome through the generation of the current by means of a gasoline motor instead of being taken from a storage battery. The simplicity of the electric is retained through the elimination of the gearset and the conventional controls of the gasoline tractor, while the comparatively large gasoline consumption of the latter, when the motor is run at normal speed during the many short stops, is eliminated by the use of a special device which automatically cuts the speed of the motor in half when there is no load on the generator.

Governor Device

The governor device consists of a solenoid of the plunger type, which is connected in the throttle lever of the gasoline motor by linkage. It is wired in multiple across the generator terminal through a contractor on the driver's controller shaft, which in turn is so arranged that a slight movement of the controller handle from neutral position in either direction will close the circuit, automatically speeding up the gasoline engine before the driving motors at the rear wheels begin to draw current. Conversely, throwing the controller to neutral automatically reduces the gasoline motor speed to half that when there is a load on the generator.

The solenoid device is locked to be tamper-proof. From the moment the gasoline motor is started at the beginning of the day's work, it is kept running without any attention on the part of the driver, its speed being regulated by the solenoid apparatus. All the driver has to do is to steer the vehicle and operate the controller, which gives five speeds forward and two reverse.

Trailers

Perhaps of equal importance with the design of the tractors is that of the trailers for the collection of garbage, ashes and paper refuse at the same time. The trailers make use of eight double-decked steel buckets, as shown in the accompanying illustration depicting the electric crane at the river-front dump lifting off the upper deck. The lower buckets are arranged in two longitudinal rows of four each, set into the trailer frame. On top of these are two other buckets with V-shaped bottoms and side doors. The latter are opened to permit the men to dump the cans of garbage or ashes into the eight buckets on the lower deck, the paper and other refuse collected being thrown directly into the upper buckets from the sidewalk.

In unloading at the disposal pier, the upper buckets are lifted off first, dumped into scows and then set down on the pier floor. Then each of the lower buckets is hoisted out and dumped in a similar manner. They are then loaded back onto the trailer in the reverse manner, when the unit is ready to return to its next point of collection.

Snow Removal

The sweeping and flushing of the streets and the plowing of snow in the winter is to be done by special trailers, but the city authorities have not yet appropriated the money for the purchase of these. The tractors were used to plow snow during the recent storms, however, by uncoupling the trailers and applying the conventional front-end plows.

Spring

With the fine weather of the last week contractors are putting their machinery in shape preparatory to the active commencement of construction work. The next five or six weeks will see more excavations completed than in the balance of the year. On the foundations depends very largely the life of a building. They should be broad and deep, going down sufficiently far to reach a good bearing surface, and in any case should be below the frost-line. Concrete for footings and foundations should receive special attention, should be well mixed, and carefully tamped in the trench to insure the maximum density. Buildings built on such foundations will never settle.

The Metals Coating Company of Canada are operating a demonstrating Laboratory at 90 St. James Street, Montreal, for the purpose of showing the highly efficient method by which metals of all kinds may be deposited on any surface. This is of particular interest to the shell manufacturers for building up short weight shells or covering iron shell clips with copper or zinc.

Road Construction and Maintenance

The Different Methods of Construction and Repair of Highway Pavements—The Necessity of a Good Organization

By W. H. Connell*

A GOOD organization is essential particularly in so far as maintenance is concerned, as it is practically impossible to continuously and systematically maintain pavements and roads in first class condition, in an economical manner, without a good working organization built up along the lines best adapted to cope with the conditions involved in this important branch of work coming under the jurisdiction of a highway department. By this it is not intended to give the impression that the maintenance organization should be separated from the construction, as separate organizations are apt to result in an overlapping of jurisdiction and a tendency to shift responsibility, and open up a field for unlimited excuses as to whether the construction or maintenance division is responsible for any unsatisfactory conditions that may arise relative to the pavements. Furthermore, it is obvious that the logical organization to maintain the pavements is the one that saw them laid and is familiar with every detail of the construction, as very often a knowledge of apparently trivial conditions in connection with the construction bears an important part in the future maintenance.

Knowledge of Details

It is the intimate knowledge of the details of both construction and maintenance, not considered separately but in their relation to one another, that is so desirable as a future guide in highway engineering; consequently the combination of the two organizations in one will accomplish far better results than they would working more or less independently of one another, each with a limited responsibility. Highway engineering may be considered a specialty, but further specializing in construction and maintenance is not logical as the two are dove-tailed and cannot be considered separately. Every engineer engaged in highway work appreciates the fact that there is no such thing as a permanent pavement for either city streets or country roads, consequently, in addition to the cost of construction, the maintenance repair charges during its life must be included in the final cost and is a most important factor in the selection of a pavement.

The main and most perplexing problem of a highway department, no matter whether the department be a State, Municipal, County or Town Department, is, or eventually will be, that of maintenance. If a large percentage of the roads or pavements are constructed, which is usually the case, then the maintenance predominates, and in fact it is only in localities where there are practically no roads or pavements, that the maintenance is subordinated to the construction.

The activities coming under the jurisdiction of the Municipal and State Highway Departments are not similar in every respect, but the principal functions do not differ sufficiently to affect the problem in the main.

A large Municipal Department embracing street cleaning, collection and disposal of ashes, garbage and rubbish, and snow removal, together with the general problems such as construction and maintenance of pavements, etc., embraces a greater variety of work than does a State Department, but principally of a nature that is essentially maintenance work. Likewise in a large State Department, with an active organization controlling a large area of improved highways, the maintenance problem is more involved and complicated than in a County or State Department with a less mileage of pavements or roads under its care, so that the perplexity of the problem increases not only with the number and variety of activities, but with the area of the territory and the mileage of roads and pavements coming under the jurisdiction of the department. It is, of course, a much simpler matter to cope with this problem where the work involved is such that it can be controlled from a central office, without delegating the responsibility to divisions and sub-divisions of the organization. This is especially true in maintenance work, as there is always a tendency among engineers to be lax in attention to details of an apparently simple and routine nature. They are apt to overlook the fact that it is no trick to construct a pavement, as in supervising this work they are simply following more or less standard and well defined principles, where, in maintenance work, there is no set specification to follow, the success depending upon attention, to a certain degree, to daily routine and principally to petty details that present themselves in the actual physical work, and in this there is an unlimited field for initiative. Personal experience in observations of the wear and peculiarities of the different types of pavements and road surfaces is invaluable as a guide in research work, as there is not a pavement today that cannot and should not be improved upon. The difficulty of impressing upon the supervising force the importance of this close personal attention to detail in connection with the care of the pavements is probably the most important single factor in the operation of a large highway department, and must be reckoned with and especially in these times when the public are becoming more and more exacting and virtually demanding that the roads and pavements be kept continuously in good repair. This should be obvious to all engineers in charge of highway organizations.

Classification of Maintenance

For convenience the different branches of maintenance work will be grouped under the following classifications:

1. Routine Maintenance.
2. General Maintenance.
3. Emergency Maintenance.

Routine maintenance includes such work as the regular street cleaning in municipalities, and the cleaning of country roads and gutters, and any other work of this character that is more or less routine and should be performed under a definite schedule. The streets in the thickly populated sections of the city should be cleaned every day; in less thickly populated sections, every other day; every third, and so on until we come to the country roads which should be cleaned once a week, once every two weeks, and some only

*Chief, Bureau of Highways and Street Cleaning, Philadelphia, before Third Canadian and International Good Roads Congress.

once a month, depending upon the amount and character of the traffic which largely governs the frequency with which the cleaning should be done. The amount and schedule of work and the force necessary to perform it can be determined upon in advance and carried on in a systematic manner under a regular organization, more or less military.

General Maintenance

General maintenance includes repairs to streets and roads, and involves different characters of work, each requiring special knowledge on the part of those engaged in the actual performance of the physical work for which special gangs have to be organized. Stone block, wood block, and brick repairs, for example, require skilled laborers who have made a specialty of this work and are employed under the title of pavers and rammers; while repairs to asphalt and bituminous pavements must be performed by men specially trained in this line of work, in addition to the necessary force engaged at the mixing plants. Macadam road repairs, the care of earth roads, and bituminous surface treatments, also require men specially trained, and while it is desirable to train the gangs for each particular branch of this work, such, for example, as bituminous macadam built by the penetration method, waterbound macadam, bituminous surface treatments, and the care of earth roads, the three classifications below are the three branches into which the organization is usually divided. Further sub-divisions can be handled by those directly in charge of the different classes of work coming under these divisions by training the laborers for the particular character of work to which they are assigned.

1. Block pavement repairs,
2. Bituminous pavement repairs (mixing method), sheet asphalt, bituminous concrete, etc.,
3. Country roads, macadam, gravel, etc., bituminous surface treatments, and earth road repairs.

This illustrates the difficulty of handling the work coming under the heading of general maintenance, which not only requires separate organizations made up of men specially trained in the different branches of the work, but the character and amount of the work itself is of such an indefinite quantity that it is very hard to control, and, furthermore, can only be performed in seasons of the year when weather conditions are suitable, all of which tends to make it difficult to maintain a good working organization, as is always the case when men are not regularly employed all year round.

The principal element leading to success in this work is the application of the theory that "a stitch in time saves nine." This not only applies to the patching of different characters of pavements, but to bituminous surface treatments, particularly when the treatment only consists of a paint-coat lightly covered with washed gravel or chips, which is only intended to last for a year or two. Very often when a treatment is required on a road and the performance of the work is postponed for a couple of weeks, the road will deteriorate and require resurfacing, so that it not only necessitates a more or less flexible organization for the actual performance of the work, but a very thorough study of the probable amount of material required, which should be purchased sufficiently in advance to avoid any delay in furnishing the material. This requires in addition to an efficient overhead organization composed of engineers well versed in the art of carrying on the work, a thoroughly systematized procedure suited to bring about the best results under the conditions to be met.

Emergency Maintenance

The third classification, or emergency maintenance, consists of such work as snow removal and taking care of extensive washouts, both of which require an emergency force, as work of this character must be performed at once and necessitates putting on an indefinite number of men, depending upon the volume of work, usually for only a short period of time. This makes it necessary for the organization to keep in touch with all available sources where men can be employed on short notice.

These are some of the reasons why the maintenance problem is the most difficult one in a highway department. Construction work, in the first place, is usually carried on under contract and all the cares and troubles relative to the labor situation are up to the contractor, the department requires the contractor to perform a specific piece of work under definite conditions and is only charged with the inspection, and the responsibility of seeing that it is performed in accordance with the requirements of the specifications. While, in the maintenance work the burden of the responsibility is up to the officials of the department not only in so far as the character of the work is concerned, but for the control of the organizations engaged in its performance.

The details of the different characters of repair work including the methods and materials used are, of course, very important, but nothing like as important as the length of time that elapses between the origination of the necessity for the repairs and the performance of the work. Repairs should be made as soon as the defects, no matter how slight, present themselves, and not weeks afterward. The secret of success in highway work is continuous and systematic maintenance. The up-keep is the real problem. The highways should be patrolled every week and oftener if necessary, and all defects reported and repairs made at once.

Patrol and Gang Methods

The general methods employed to maintain a system of highways in good condition are the patrol method and the gang method. The patrol method usually consists in having a man with a team and the repair equipment patrol and be responsible for making repairs to a certain, definite length of highway. The gang method consists in sufficient gangs being employed, equipped with all the materials to make repairs where ordered, the difference between the two methods being that in the first method the man who makes the repairs also patrols the highways, while the gang method is dependent upon the reporting of defects being made by special patrolmen, who may be inspectors, engineers, etc. There is some difference of opinion as to the better method, but it would seem that the reporting of the necessity for repairs by a special patrol inspector and the making of these repairs by a specially trained gang would be the better method. A detailed description of the methods of making repairs to the various types of roads and pavements would constitute quite a voluminous document. Consequently, it will only be possible to discuss the fundamental principles.

Dirt roads should be well crowned and drained. The shoulders should be kept clear, and the drainage ditches open. Road drags and road scrapers must also be used from time to time in order to keep dirt roads in good condition. An application of about a 20 Beaume gravity road oil once a year will not only lay the dust, but will help to compact the road surface under travel and form a sort of crust.

Gravel and waterbound macadam roads should be well crowned, well drained, and the shoulders and drainage ditches kept clear. The most effective method of maintaining gravel and macadam roads is through the use of bituminous surface treatments. The method and type of treatment used, however, will depend upon whether it is to be used for a gravel or macadam road and the character of gravel and stone used in the construction of the respective types of roads. On other classes of roads and pavements, such as bituminous pavements by the mixing and penetration methods, cement concrete, brick and stone block pavement, it is also important to keep the roads well drained, the shoulders clear, and the drains and ditches open. The methods of bituminous surface treatments used on the City of Philadelphia suburban and country macadam and dirt roads are as follows:

Suburban and Country Roads

The suburban and country streets and roads receive bituminous surface treatments of the character best suited to the respective roads, which are selected only after making a study of the type of construction, the traffic and social and local conditions in each instance. Generally speaking, two methods of treatment are used on the roads. For convenience they are divided, first, into bituminous surface treatments, intended to eliminate the dust nuisance and preserve the roads, and secondly, a cheaper method of bituminous surface treatment, used simply for the purpose of laying the dust on macadam, cinder and dirt roads, and not intended to preserve the road to any great extent.

The first method of treatment is used only on macadam roads that have been put in good condition, as it is a waste of money to put a high class bituminous surface treatment on a road that is full of ruts and pot holes and not properly shaped up.

The bituminous materials used in the City of Philadelphia consist of coal tar treatment, hot application, known as Tarvia A, coal tar treatment, cold application, known as Tarvia B, water gas tar treatment, hot application, known as Ugite No. 2, water gas tar treatment, cold application, known as Ugite No. 1, and asphalt cut-back treatments which consist of a mixture of 60 per cent. to 65 per cent. of 80 to 100 penetration asphalt, conforming to specifications adopted by the Association for Standardizing Paving Specifications at Pittsburgh in 1913, and 35 to 40 per cent. of 53 to 60 commercial naphtha. All of these materials are applied in quantities just sufficient to paint the road and to avoid possibilities of building up a pad. In other words, the purpose is simply to have a film coat of bituminous material on the surface of the road and to re-treat the road as often as is necessary to maintain the film coat, and in this way eliminate the pushing and rolling under traffic, which occurs with bituminous pads.

Method of Application

The method of applying these bituminous materials, when the road is in proper condition to receive such a treatment and the material to be used on the respective roads has been selected, is as follows: The roads are first lightly sprinkled with water and then swept with a horse-drawn broom. They are then swept with hand brooms until the surfaces of the stone are free from dust. This sweeping, however, should not be done in such a manner that the stone dust or binder will be removed from between the stones. The bituminous material is then applied with a pressure distributor at a certain rate per gallon which varies on different roads, depending upon their condition, and also whether it be a first, second or third treatment. The bituminous material is then allowed to remain on the road for about twelve hours or over night, after which fine washed gravel—

Passing ½ inch screen 100 per cent.
Passing No. 4 screen 50 to 60 per cent.
Passing No. 6 screen 20 to 30 per cent.
Passing No. 10 screen not over 10 per cent.

is spread over the road at the rate of 13 to 18 pounds to the square yard, depending upon the amount of bituminous material applied. In some cases clean trap rock chips passing a ⅝-inch ring and maintained on a ⅜-inch ring are used.

The theory of using fine washed gravel in place of stone chips is two-fold; first, to use a covering that will grind up and pulverize before the bituminous material has set up, and thus incorporate with it and build up a pad, such as is the case with the stone chips as they pulverize very quickly under any appreciable amount of traffic; second, it only contains 10 per cent. of the fine sand and the pebbles constituting the rest of the material are so hard that they do not grind up and pulverize for from three weeks to two months, depending upon the traffic. The process of pulverizing is so slow that the fine material is washed off the road after each rain, thus doing away with the necessity of sweeping the road to eliminate the dust, which is necessary where stone chips are used.

These treatments last for a year and have proved to be not only the most economical method of preserving roads of this character, but the cost is less than the cost of sprinkling with water provided the roads are sprinkled three times a day and this, by the way, is not sufficient to lay the dust, and, of course, it must also be understood that the sprinkling with water will not preserve the roads under automobile traffic.

Use of Asphaltic Oil

The second class of treatment generally used consists of asphaltic road oil from 18 degrees to 23 degrees Beaume gravity. This material is applied to all of the macadam roads that are not in fit condition for the first-class bituminous surface treatment and to all dirt roads, and is applied at the rate of 2/10 to ¼ gallon to the square yard. On some roads, depending upon the amount of traffic and whether or not the road is shaded, it is necessary to treat the road in May and treat it again in September. Such roads, however, are the exception. In most cases this method of treatment will last for one season. The roads as a rule are not swept before the application, nor is any covering put over this bituminous material, as it is applied in such small quantities that there is scarcely any necessity for covering. The purpose in putting on this small quantity is to insure its disappearing from the road before the winter sets in, in order to avoid the mushy condition that prevails when there is too much oil on the road in this season of the year.

The paint coat method of tar bituminous surface treatments on first-class macadam roads has been a success for seven or eight years in this country, and it has also been used to a very great extent for a number of years in England.

The asphalt cut-back paint coat treatments are somewhat new, and have been largely developed in Philadelphia during the last four years. The successful results in Philadelphia have led to its use in other localities in the east this year, notably by the Highway Department of the State of Pennsylvania, where a large mileage of roads have been treated using this method.

The asphalt cut-back bituminous surface treatment, was evolved through research work carried on with a view to finding some way to utilize an asphalt in the paint coat method of treatment which had been so successful with the tars. In order to do this, it was necessary to use a comparatively stiff asphalt so that it would set up quickly on the road. This necessitated cutting back an asphalt of about 100 per cent. penetration with from 35 per cent. to 40 per cent. of naphtha. The purpose of the naphtha is to make the material of such a consistency that it can be applied to the road when it is moderately warm. In other words, the naphtha simply acts as a carrying agent and after it has done its work, it evaporates and leaves the paint coat of asphalt on the road.

This material has proved to be a success under a four year test, re-treating, of course, every year or two, or as often as is necessary, as is also the case with the tars.

The methods of bituminous treatments described, however, are not applicable to all conditions. The roads treated must be built of comparatively hard stone, and the traffic conditions must be taken into consideration.

Range of Application

The method of bituminous surface treatment described for macadam roads built of hard stone and in good condition can also be used on gravel roads constructed of materials similar to what is commonly called Poughkeepsie gravel, which consists of large and small sized stones with fine gravel for a binder. Where the gravel is composed of any appreciable amount of clay, this method of treatment would not give very satisfactory results. The dust layer referred to, however, would benefit such roads to a considerable extent. In discussing these bituminous surface treatments it will be noted that great stress has been laid on a paint coat or film coat to be renewed each year or so, or as often as necessary. The object of this paint coat or film coat is to avoid the formation of a pad, but where the road is built of soft stone that would naturally be affected more by traffic than would the hard stone, this paint coat or film coat would not be satisfactory. In such cases, it would be necessary to use a larger amount of material and build up a ⅜ to ½-inch pad. It is practically impossible to give any general description for bituminous surface treatment work that will apply to all conditions, but there is no road that cannot be benefited by the application of bituminous surface treatments. It is, however, very important that all the details of the cleaning, etc., previously described should be given very careful attention, and the roads should be re-treated before they have gone into a condition of bad repair. After these re-treatments have been applied, that does not mean that they will not require any attention until the following year. Some roads, of course, will not require any attention until the time for the re-treatment, but a great many of the roads where the traffic is heavy will require patching all through the winter. The methods used in patching these bituminous surface treated roads in Philadelphia are as follows: Where the surface treatment has worn off in spots and there is likelihood of a pot-hole forming, the road is painted with tar used for cold treatments or asphalt cut-back, depending upon the character of material the road was originality treated with, and chips or gravel spread over the area of the surface, that has been painted. Where pot holes have formed, a mixture of ¾-inch stone and a heavy tar somewhat similar to Tarvia A or an asphalt of about 100 penetration is placed in the hole and tamped, and dry gravel or chips spread over the surface. This can be done by heating the tar or asphalt on the road and mixing it with the stone. But a more effective and better way to handle this kind of patching is to make up a mixture of the tar and stone and the asphalt and stone and place it at different locations along the line of the system of highways. By the use of a suitable mixture of asphalt or tar cut back with naphtha, it is possible to prepare large quantities of patching material which will not set up so that it cannot be re-handled and used for repair work during the winter, without the necessity of re-heating. This is known as the cold mixing method of patching bituminous macadam and bituminous surface treated roads. Such materials as Amiesite and Bicomac are also adopted for winter patching and have given very satisfactory results. The main point that should be, and has been, brought out in connection with repairs to roads and pavements of all descriptions is to make the repairs promptly when there is the slightest indication of the necessity for repairs, and thus avoid pot holes in the country roads and necessity for making extensive repairs to roads and pavements of all descriptions.

Now that you are building a large mileage of highways in Canada, it will not be long before your maintenance problem will predominate as it will be looming up larger each year, and you have a splendid opportunity to avail yourself of the experience gained by the failures in other localities where there has been a great deal of highway construction. In conclusion, it will not be an unfair statement to say that the failures in highway construction have been very much exaggerated. The trouble has been principally, however, the failure to maintain the roads and pavements after their having been constructed.

Trade Inquiries

Names and address may be had on application to the Department of Trade & Commerce, Ottawa.

260. **Reinforcing rods for concrete construction**—A New York firm of exporters desires to be placed in touch with Canadian manufacturers of reinforcing rods for concrete construction for shipment to Great Britain and Indian ports.

271. **Wire.**—In 22½, 23 and 24 gauge. Quotations for ten tons c. i. f. Glasgow.

273. **Boiler tubes.**—Either lap-welded or solid drawn. A Glasgow firm is prepared to receive quotations for the above.

277. **Scrap-iron.**—A Glasgow firm wishes to import heavy wrought-iron scrap, used iron or steel railway axles, shipyard steel scrap.

278. **Steel wire, nuts and bolts.**—A large Glasgow concern, at present importing from the United States, will be pleased to receive quotations for bright, mild steel wire, bright hexagon and square nuts, small bolts, etc. Would prefer to give Canada preference.

The Use of Vitrified Clay Segment Blocks in Sewer Construction

By J. M. Egan, Jr., C.E.*

At the present time, there are on the market two vitrified sewer blocks of different design, one being a single-ring block and the other a two-ring block. The single block has a ship-lap joint on the ends and a tongue and groove joint on the sides, while in the double block, the laps and joints are made in the construction of the sewer and the blocks are placed one on top of the other as in a two-ring brick sewer. The blocks are hollow longitudinally with web braces. They are made for sewers varying in size from 30 to 108 inches in diameter, and according to size, weigh from 40 up to 120 pounds, are 18 and 24 inches long, are from 9 to 15 inches wide, and are from 5 to 10 inches thick. Short lengths are also made for convenience in construction and for use on sharp curves. Special blocks are also made for connections and junctions and consequently this type of sewer is as flexible as any pipe, brick, or concrete sewer. The blocks are also made for use in egg-shaped sewers, in which case, an extra heavy base block is furnished.

Excavations

In constructing the sewer with the blocks, the method of excavating the trench does not vary from methods used in constructing sewers of other types. If the soil excavated is stiff enough to permit, the bottom of the trench should be shaped to conform to the outside of the sewer, thus forming a good foundation and eliminating excessive tamping. A template may be used to procure this shape as well as a means of guidance for laying the blocks. The first block is laid in the centre of the trench to line and grade and the blocks comprising the invert are laid to it. As the blocks of the invert are laid up, care in back-filling behind the blocks must be practised. The joints, both end and side, must be mortared about ¼ in. thick, and the blocks must be laid broken or staggered. The joints of the invert may be pointed up as they are laid. Careful tamping on each side of the spring line behind the blocks will give much added strength to the sewer and this tamping should continue to the second course above the spring line. Wooden forms are used for the arch and are usually placed a little bit higher than the required diameter in order to allow a little wider space for the key block. The blocks are then laid up on either side of the form, the key block finally inserted, the form immediately removed, and the arch will then settle into place and form the correct diameter. Back-filling can then be started at once. In laying these blocks, experienced bricklayers are not needed, as the ordinary pipe layer can soon pick up the art of laying the blocks. If wet and quick sandy conditions prevail in the trench and sheeting is necessary, it must be driven low and cut off and left in the trench below the spring line. In cases where steel sheeting would be used, very careful backfilling must be resorted to and as the sheeting is slowly pulled, water flushing must be carried on as it is very necessary that a good bearing be given the invert. In cases where the soil conditions in the trench bottom are very bad, planks may be laid under the first block or a cradle may be used for holding the first few blocks. However, there are no disadvantages in using the block in bad trench work not encountered in using other materials and it is claimed by some of the engineers that have used them in bad trench conditions, that they are to be preferred to any other type of material.

Cost

The cost of laying the blocks, of course, varies with the efficiency of the contractor and his organization, and with the varying labor conditions. It should not exceed 1 cent per inch in diameter of the sewer per lineal foot; this to include labor of laying, cost of mortar, and backfilling up to the spring line. The cost of the block is moderate and has the advantage over the large sewer pipe in that it takes a smaller freight rate, the breakage in transit is exceedingly small, and the cost of handling from cars to trench and in the trench is low as it is easily a one-man job. The cost of the block sewer complete is undoubtedly lower than the cost of either the brick or reinforced concrete sewer, and on account of its lower coefficient of friction, smaller sewers may be used with as good results as larger sizes of the other two materials with a consequent lowering of cost. There is only 7 per cent. of surface exposed to the jointing material in the block sewer as against 28 per cent. in the brick sewer, and the highly glazed impervious block is certainly superior to the ordinary sewer brick. Good speed in construction can be made and it is not necessary to have much trench open ahead of the block laying and, as mentioned before, backfilling can be done as soon as forms are lowered and the work cleaned up generally as it progresses. All of these points tend to lower the cost of this type of sewer with the advantage of giving a more efficient structure.

Good connections can be made between segment block sewers of different size as well as between segment block sewers and pipe lines. The segment block sewer can also be adjusted to fit sharp curves with very little loss of efficiency. Special blocks are made for the small connections with the pipe molded to the block and in the large sizes, four or six adjacent blocks are so molded in the manufacture to permit of the entrance of the large pipe and thus saves any cutting or chipping of the block on the construction work.

Adaptability of Segment Blocks

These blocks, while being particularly adapted for use in constructing storm and sanitary sewers, are also coming into use as outlet drains for large farm drainage projects instead of small open ditches. They can also be used for service tunnels as well as for highway culverts. Sewers of vitrified clay segment blocks have been constructed during the past few years in many large cities.

Both internal hydrostatic pressure and loading tests have been carried on in connection with this type of sewer and the results of these tests may be obtained from the manufacturers and testing laboratories, it being enough to state here that the strength of the blocks have proven ample and sufficient for the use for which they are made. Examinations of segment block sewers have been made after they have been in use for some time and the reports are that they are in good shape.

* Before Illinois Society of Engineers and Surveyors.

New Steel Bridge, Trenton

Substantial progress is being made on the new steel bridge over the Trent River at Trenton, Ont. This structure will replace an old covered-in wooden causeway with a light steel swing span, and is being built on the same site as the old bridge.

The substructure was commenced early in October, 1915, and, favored with mild weather, excellent progress was made, considering the obstacles to be overcome in placing the concrete piers in 16 to 18 ft. of water. Due to the fact that this bridge offers the

The Old Bridge at Trenton, Ont.

only means of communication between the eastern residential section and the western business section, the erection of the superstructure was held up, due to mild weather in January, until traffic could be maintained over the ice. Steel erection commenced on January 15, and was completed in forty days, including lost time.

The total length of the bridge between abutments is 560 ft., which includes three fixed spans 119 ft. centre to centre of pins, and one swing span 200 ft. centre to centre. There is a 24-ft. roadway between trusses, and two 5-ft. sidewalks. The floors on the fixed spans are concrete, while a double wood floor is placed on the swing span. The capacity of the bridge is given as twenty tons on two axles with 10-ft. centres. The swing span is operated either by hand or by electricity. The general contract for the entire structure was awarded to the Ontario Bridge Company, Limited. A more detailed description will be furnished on completion of the work.

Regent Theatre, Montreal

The Regent Theatre is the latest addition to the suburban moving picture houses in Montreal. It is situated on Park Avenue, in the north end of the city, and is by far the best equipped of any similar place of amusement in Montreal's outlying districts. The dimensions are—frontage 50 feet; depth 104 feet; and height 60 feet. The building is of reinforced concrete on the Kahn system; the roof is of 48 in. steel girders, while the span of 50 feet is without intermediate support, thus giving an uninterrupted view of the stage. The front portion of the theatre is faced with terra cotta, with just sufficient ornamental detail to emphasize the lines and proportions.

On entering the foyer, which is lined with marble and has a vaulted roof, there are two marble stairways on the right and left landing to the gallery which gives accommodation for about 500 people. Two wide stairways, with stone steps, provide entranceways to the seats. The front section of the gallery constitutes the family circle, fitted with easy chairs and separated by brass rails from the position. Between the main floor and the gallery is a mezzanine floor, above the entrance, on which is situated the board room and secretary's office. The auditorium has three aisles, and has accommodation for nearly 700 spectators. Under the overhang of the gallery is a vaulted dome, with concealed lighting in the ceiling. Two small flights of stairs give access to the boxes on either side at the stage end. The internal plaster details were designed by Mr. Hubert Tompkins of Montreal. The walls and ceilings are panelled and decorated in green, cerise, and old gold, with the glare of the lighting softened with green and amber leaded glass shades.

The main heating and ventilation equipment is situated in the basement, the system being designed by Mr. Fred Hoadley, of Montreal. The blast system of ventilating is used with an exhaust fan on the roof. Heat is provided by two low pressure steam boilers.

The building is made as fireproof as is practicable; there is very little lumber used, all the floors being either of concrete or terrazzo, and the stairways of marble or stone.

The architect was Mr. D. J. Crighton, of Montreal, who designed the theatre for the Independent Amusement Company.

The general contractors were the Nicholson Constructions, Limited, Montreal, and the sub-contractors: structural steel, Structural Steel Company, Montreal; roofing, Douglas Bros.; heating and ventilation, T. H. Higginson, Limited, Montreal; plumbing, John A. Gordon, Montreal; plastering, Geo. H. Knott and Company, Montreal; painting, Castle and Son, Montreal; ornamental iron work, Union Architectural Iron Works, Montreal; lighting fixtures and marble and tile work, the Robert Mitchell Company, Montreal; wiring, Philip Lahee and Company.

New Steel Bridge completed March 9th.

List of Manufacturers for Russia

The Russo-British Trade Exchange, Limited, 16 Regent Street, London, England, recently published in book form a list of English manufacturers, which has been distributed throughout Russia. This Exchange now announces that a similar book covering Canadian manufacturers is in course of preparation, and that information may be obtained from the McCann Advertising Agency, Toronto.

Paid Visit to Battle Front

Mr. E. A. Dunlop, M.L.A., of Pembroke, was the guest of the Canadian Society of Civil Engineers at a luncheon in the Russell house, after which he gave a very interesting address on his recent trip to the western battle front.

Mr. Dunlop while at the front was the guest of the Canadian Army Headquarters staff and thus had special opportunities of observing the organization and condition of the British Army, and more particularly the Canadian troops. The speaker graphically described his trip across the English channel in a torpedo boat destroyer and the organization the British navy has for protecting the channel. In describing the very efficient measures taken at the front to look after the welfare of the men in the trenches the speaker paid a very high tribute to the efficiency of the engineering service.

Work of Canadian C. E.

The work of Col. Mitchell, a member of the Canadian Society of Civil Engineers, and head of the Canadian Intelligence Department, was specially mentioned. Mr. Dunlop had the unique experience of entering front line trenches during daylight, and on Hill 63 he had an opportunity of seeing the German trenches as well as portions of the ground held by them. Mr. Dunlop contrasted the view taken by the people of France with the people of England and Canada. In France the old men and boys and the women are doing all the work keeping the roads repaired, etc. In Paris places of amusement are all closed, hotels, etc., are turned into hospitals and all privately owned automobiles are given over for war purposes.

The Need for Economy

In conclusion Mr. Dunlop particularly pointed out the absolute necessity for every one in this country to economize and give up all unnecessary luxuries in order, not only that the cost thereof may be saved, but that the labor used in the production of same may be utilized for the production of munitions and other defensive purposes.

The meeting was presided over by Mr. John Murphy, chairman of the branch. A very hearty vote of thanks was moved by Mr. C. R. Coutlee and seconded by Col. Anderson, after which Sir Mackenzie Bowell, the veteran Canadian statesman, made a short address in which he impressed upon the members the necessity of everyone contributing his share to the defence of the Empire.

The Town of Mount Forest, Ont., have just awarded a contract to the Turbine Equipment Company, Toronto, for one million Imperial gallons a day De Laval centrifugal pump, to be operated by a 50 h. p. Canadian Westinghouse motor. This equipment will be installed in the Mount Forest Waterworks pumping station.

Mr. Ernest McCullough, for many years a well known consulting engineer who has specialized largely on reinforced concrete design and construction, has recently become identified with the Portland Cement Association, 111 West Washington Street, Chicago. Mr. McCullough will be known officially in his new connection as Chief Engineer, Fireproof Construction Bureau.

Hudson Bay Railway Progress

The total expenditure on the Hudson Bay Railway and terminals to December 31st, 1915, was $15,465,304, according to a statement by Hon. Dr. Reid, made up as follows:—

General expenses, engineering, etc.		$ 721,974
Le Pas bridge and terminals		388,172
Le Pas Thicket Portage:		
On contract account	$3,229,994	
Rails, bridges, etc.	2,680,896	
		5,910,890
Thicket Portage to Split Lake Junction		1,661,291
Split Lake Junction to Port Nelson		1,815,869
Port Nelson terminus		4,977,208

The length of the line from Le Pas to Port Nelson is 424 miles, and the road has been graded to mile 378. Steel has been laid, including sidings, to mile 242, at which point erection is proceeding with the Manitou Rapids bridge over the Nelson River. This work, it is expected, will be completed in April when track work will be resumed. The track is surfaced to mile 225. The telegraph line keeps pace with the steel and has now been laid to mile 242.

The work is divided into three sections, and all three contracts are held by J. D. McArthur and Company. On section 1 $3.229,994 has been expended to date, on section No. 2 $1,602,300, and on section No. 3 $1,865,795, a total of $6,698,089. The total value of the work under contract is estimated at $9,629,605. During the coming summer the track will be carried forward to the second crossing of the Nelson River at Kettle Rapids at mile 332. Here there is a large bridge to construct and it is not expected that track work can proceed beyond this point until the spring of 1917.

Mr. D. H. McDougall

Mr. D. H. McDougall, the newly-appointed general manager of the Dominion Steel Corporation, has achieved his present position by dint of unremitting labor, by tactfulness and courtesy under the most trying circumstances, and by a most characteristic modesty.

Mr. McDougall was born in Glace Bay, Nova Scotia, and has been connected with the Dominion Coal Company and the Dominion Iron and Steel Company since a boy. The new general manager entered the survey staff of the Coal Company, afterwards joining the engineering staff of the Steel Company. He spent several years in the employ of the New York Central as an assistant engineer, coming back to the Steel Company to become field engineer. Mr. McDougall was then appointed as superintendent of mines and quarries in charge of the Steel Company's ore and limestone mines, and the general provision of raw materials. In the beginning of 1910 Mr. McDougall was appointed as assistant general manager of the Dominion Coal Company, Mr. M. J. Butler being at that time general manager of the Dominion Steel Corporation. On Mr. Butler's retirement from this position, Mr. McDougall was appointed general manager of the Coal Company, having throughout also retained his position as superintendent of mines and quarries of the Steel Company.

Mr. McDougall's position now involves direction of the coal mines at Glace Bay, and at Springhill, of the Steel Company's operations in Sydney, of the ore mines at Wabana, the limestone quarries at Marble Mountain and Georges River, C. B., at Port-au-Port, Newfoundland; of extensive lumbering operations and saw mills around Springhill and in New Brunswick; of two railways, namely the Sydney & Louisburg Railway and the Cumberland Railroad.

Mr. McDougall is president of the Mining Society of Nova Scotia, a vice-president of the Canadian Mining Institute, a member of the Institution of Mining Engineers (England), and a member of the Canadian Society of Civil Engineers.

Mr. A. W. Wheatley

Mr. A. W. Wheatley, president of the Lima Locomotive Corporation, Lima, Ohio, was born October 12, 1870, at Ashford, Kent County, England. He is a son of William Wheatley and of Agnes (Holly) Wheatley, both of English birth and ancestry. At the age of fifteen years he began as a rivet boy in the shops of the South Eastern Railroad, and in 1887, apprenticed himself as a machinist, attending night school. In 1892, he came to America and entered the employ of the Northern Pacific Railroad at Brainerd, Minn., as machinist; in 1893 was transferred to Staples, Minn., in the same position. In 1895 he was made foreman, occupying that position until 1900; transferred to Livingston, Mont., as general foreman in December, 1902, and later was made master mechanic of Yellowstone Division, headquarters at Glendive, Mont. In June, 1903, was appointed shop superintendent at Brainerd, Minn., and in April, 1904, was appointed general master mechanic of the entire system of the Northern Pacific Railway. In February, 1905, he accepted a position on Rock Island Railway as shop superintendent at Moline, Ill.; March 1906, accepted position as assistant superintendent of motive power of Union

Mr. A. W. Wheatley.

Pacific Railway with headquarters at Omaha. June, 1907, entered the employ of the American Locomotive Company at Schenectady as general inspector. December, 1907, was transferred to Montreal, Canada, as manager of American Locomotive Company's plant in that city. November, 1910, was transferred to Dunkirk, N. Y., in charge of that plant. June, 1911, accepted an offer from the Canadian Locomotive Company at Kingston, Ont., and was chosen as vice-president and general manager of that company, which position he resigned March 1st of this year to accept the presidency of the Lima Locomotive Corporation.

Pro Patria

Lieut. Hugh Heaton prior to the war was a student in the School of Practical Science in the 1916 class and he was serving his apprenticeship in the office of Mr. F. S. Baker. In May, 1914, he went to England to join Martin Baldwin, of the office of Sproatt & Rolph and the two spent the early summer on a bicycle trip throughout England, sketching and studying architecture. On the day war broke out they were both in London and immediately enlisted as privates in the King Edward Horse. Early in 1915 Heaton obtained his commission in the 8th Battalion King's Own Royal

Lieut. Hugh Heaton.

Lancaster Regiment and Martin Baldwin obtained his commission in the 9th Lancashire Regiment. Early in September Lieut. Heaton went over to France and since then he has been stationed near Ypres. News has just been received giving particulars of his wounding at the Ypres Salient. His Battalion, after a long stay in the international trench had been relieved and during their absence the relieving Battalion lost the trenches. On their return the King's Own proceeded to retake the trenches and it was during these operations that Lieut. Heaton was wounded. He was in command of a machine gun section. A memorandum has been received from a Tommy who saw him fall. He says that he was on the edge of a dyke and fell, badly wounded, into water, which was knee deep. He offered to help him, but Heaton refused to allow him to remain and sent him on fearing that the gun section was being cut off. He reported the incident and Lieut. Heaton was taken to the Relieving Station at Abeele. He was badly wounded by several bullets across the stomach, in the buttocks and in the left arm. For his conduct in these operations he has been awarded the Military Cross. For ten days he was reported by the War Office to be in a dangerous condition, but latest reports from the Red Cross Hospital at Le Touquet state that he is "wonderfully better and daily improving."

Mr. A. G. Hillberg, hydraulic engineer, New York City, is distributing reprints from the Engineering Record covering his papers on the design of intakes, scroll cases, and turbine draft tubes for single-runner turbines.

In the Public Eye

A budget of comment presented in the interest of public welfare, independent of party politics and with malice toward no one.

My friends have been wondering what has become of me recently, and enquiring about my silence. I have not been asleep. I have been very much awake, watching with wide open eyes the course of events at Ottawa. I have seen the storm clouds gathering for an outbreak that is likely to end at an early date in a political cyclone. But what was the use of continually hammering away and telling about crooked letting of contracts for shells and shell boxes? I just got sick and tired of the job, but I could see the chickens poking their heads over the horizon on their way home to roost. So I settled down to wait until they began to flutter into the government coop and start something. A good many of the flock have reached home already and others are on the way.

"I told you so"—that is the way I feel about it all just now. When I began saying things about profiteering and crooked contracts generally in connection with supplying war materials, perhaps some readers thought I was going it pretty strong. I only wish I could have gone it a good deal stronger. However, this paper takes a good deal of pride in the fact that at a time when the public knew very little about the real state of affairs it was the first paper in Canada that had courage enough to come out clearly and draw public attention to what the Shell Committee was doing. From that day to this, every single day has been adding to the justification of our course.

* * *

Today we are told on the responsibility of a member of parliament that things appear to be even more rotten than we had thought. The latest charges are briefly as follows:—

That while Canadian firms were unable to get contracts for the production of time fuses, two United States companies, which were simply middlemen, received fuse orders amounting to $23,000,000 and were given cash advances amounting to $3,252,900 as an inducement to take the contracts;

That one of these companies was the American Ammunition Company, a mushroom company, with capital of $1,000, having no plant, which received orders for about $12,000,000 worth of fuses and an advance of $1,565,400 in cash;

That the other company was the National Arms and Fuse Company which got a contract for $11,250,000 worth of fuses and an advance of $1,687,500, being also a mushroom company, with capital of $3,000, and no plant;

That one E. B. Caldwell, president of the International Arms and Fuse Company; one B. F. Yoakum, New York, and one E. N. Bassick, Bridgeport, Conn., entered into a written agreement to divide $1,000,000 for getting contracts from the shell committee, before such contracts were in writing;

That Col. J. Wesley Allison was in an agreement with Yoakum and one Eugene Lignanti, an orchestra leader of Montreal, to secure contracts, and that Lignanti disposed of his one-tenth interest for $50,000;

And lastly, that General Hughes gave his formal approval of Allison's transactions.

Are not the indications pretty strong that the government we have in Canada to-day is about the rottenest we ever had, and that it is led by about the weakest leader imaginable? Such is the general opinion on the street to-day. While we in Canada have been straining every nerve and every muscle to do our share as a part of the Empire, to lead cleaner lives, and to help along the great task of defending the Empire against her foes, some of our trusted representatives in Parliament appear to have been bending all their energies and using every favorable opportunity for private profiteering.

* * *

There are many other things besides these war contract matters that the country wants to learn about. Many of us would like to know, for instance, about those Canadian officers now in England, some 1,500 I am told, who are doing nothing, so far as we can learn, but draw their pay just the same—living at the expense of the country.

* * *

Now that possibly the most strenuous period of the war is over, the Government seems to be willing to make something in the way of a bluff at protecting the Canadian people, by appearing to prohibit the export of nickel to our enemies. Just what this bluff is based upon we may not know, but it is said that the government's nickel policy is really controlled by two ministers, one at Ottawa and one at Toronto. I do not know about this, but would like someone to ask the government about it.

* * *

It must not be lost sight of that a strong Liberal vote—the silent vote—placed the Borden party in power.

This vote is not going to be satisfied with anything but the fullest investigation of the Shell Committee. Sir Robert Borden may think that by throwing dust in the eyes of the country he will save the party, but the "silent" vote waits round the corner.

Sir Sam Hughes as the "goat" will not satisfy. It is difficult to imagine Hughes so openly grafting (?) as claimed. The egotism of the Minister of Militia—appears an ass to the public—is equally distasteful to all of us, but there are many works and deeds to his credit.

* * *

It is folly for Borden and his cabinet to claim ignorance of what is going on. Did Hughes carry on these tremendous transactions unknown to the Cabinet? Did he draw those enormous sums of money unknown to Sir Thomas White, drop the Customs barrier unknown to Hon. J. D. Reid? Surely Hon. A. E. Kemp, under obligation to Sir Sam and the Shell Committee for many large orders, must have known.

Sam Hughes may come back and deny the charges. He has nerve enough to face any old charge, but will he stand being made the "goat." I don't believe he will and I don't believe the government dare make a goat of him.

No man should be in the Cabinet who is interested in contracts.

SEARCHLIGHT.

Personal

Mr. R. C. D. Tempest, resident engineer of the sewer section, Toronto, has resigned on account of ill health.

Mr. H. G. Girvin, chief chemist of the Steel Company of Canada, delivered an interesting address on Iron and Steel before a large and appreciative audience at the Technical School, Hamilton, on March 27.

Mr. Tom Moore, of Niagara Falls, Ont., organizer for the Carpenters' Union, says that members of this trade are enlisting in large numbers. He estimates that 12 per cent. of the organized carpenters have enlisted already. There are about 8,000 carpenters in the Union at present.

Obituary

Mr. John Flook, of Chatham, Ont., one of the best-known marine contractors in western Ontario, died suddenly on March 26. He had been a contractor on pier and breakwater construction for nearly half a century. He constructed the Tecumseh Park breakwater at Chatham and the first piers at Erieau, as well as many other works.

Mainly Constructional

East and West—From Coast to Coast

The Canadian Welding Works, Limited, Montreal, Que., have registered.

The Union Cement Company, Owen Sound, Ont., have commenced work for the season. They have a contract to supply 100,000 barrels of cement to the city of Toronto.

The work of rebuilding the Princess Theatre at Toronto, which was burned to the ground a year ago, is to be begun immediately. It is planned to open it on September 15.

Work on the Bloor Street Viaduct, Toronto, was stopped by the unusually heavy flood on the Don River last week. There was no loss around the viaduct, however, all the low-lying concrete having been finished.

According to figures compiled from tests made a year ago at the new waterworks plant at Sarnia, Ont., the city at the present time is losing close on $25,000 a year from water wastage.

Preparations are being made by the Canadian Stewart Company to proceed with the Harbor Improvement work at Toronto. The ice in the bay is expected to break up shortly, and construction work will proceed as soon as the tugs can get out.

It is stated that the Empire Hippodrome Company has taken out a charter for $1,000,000, and as soon as plans are perfected will erect a mammoth theatre at the corner of College and Teraulay Streets, having a seating capacity of from 4,000 to 5,000.

The Economy Foundry Company, of Portage la Prairie, Man., have received a contract to furnish all the ornamental iron work required in the new building for the T. Eaton Company at Winnipeg. The contract is worth about $25,000, and work on it is to begin immediately.

Some thirty-five members of the Calgary Branch of the Canadian Society of Civil Engineers attended the fourth dinner of the season, held on March 16, and after the repast enjoyed an address by Mr. G. N. Houston, of Denver, on the legislative control of civil engineering.

The Bloor Street Bridge over the Humber River, Toronto, has been swept away by the ice carried downstream by the swollen and swiftly-flowing current as the result of the spring thaws. The bridge had a span of 100 feet. It will probably be replaced by a new steel bridge.

At a recent meeting of the Toronto Bricklayers' Union, No. 2, of the International Union, the members decided each to give a day's pay for the purpose of keeping in good standing those of their number who are fighting the Empire's battles. Twenty-five per cent. of the members have enlisted

Trail, B. C., will be the scene of considerable activity in the building line this spring. Projected plans include a new fire hall, a school building costing about $15,000, and a building for the Trail Mercantile Company at a cost of from $8,000 to $10,000, in addition to a number of residences

The Laberge Lumber Company, Limited, of Sudbury, Ont., have secured from the Canadian Copper Company, of Copper Cliff, contracts for the building of twenty-one lodging houses and a store at Mileage 17 on the Algoma Eastern A start has been made with three gangs, and the work is being rushed to completion.

The town of Mount Forest, Ont., have just awarded a contract to the Turbine Equipment Company, Toronto, for one million Imperial gallons a day De Laval centrifugal pump, to be operated by a 50 h.p. Canadian Westinghouse motor. This equipment will be installed in the Mount Forest waterworks pumping station.

The Ottawa Board of Control have recommended to the City Council that the building by-law, limiting the height of buildings to 110 feet, be amended to make the maximum height 130 feet. There is some opposition to this, on the grounds that the Board of Control are violating their agreement with the Town Planning Commission.

The Builders' Exchange of Stratford and Perth County, Ont., which meets each week, reports the organization to be in a very flourishing condition. A membership of over thirty has been secured already, and this will reach the forty mark in time for the annual meeting, which will be held shortly. All branches of the building trade are represented.

A defective flue was the cause of a fire which partly destroyed the oldest building in Truro, N. S., "The Cottage," the residence of the late Sir Adams Archibald. The building was of quaint architecture, in the old English style, and was erected nearly one hundred years ago by the Rev. John Burnyeat, an Anglican missionary in Truro from 1820 to 1835.

An asphalt road is planned to be built between the city of Quebec and the concentration camp at Valcartier. The cost will be around $3,000 a mile, or a total of some $125,000, the larger part of which will be borne by the Provincial Roads Department. Work is to be started as soon as the snow melts, and alien enemies will be employed principally.

The Municipal Building of Walkerton, Ont., which was built in 1897, is showing many defects as the result of the sinking of the foundations. The council have condemned the hall for use, and the architect was asked to report on it. He recommends the building of two buttresses each on the west and north sides, which work will be carried out at a cost of $1,500.

It is reported in Calgary that the cement plant at Dauntless, south of Medicine Hat, Alta., which has remained in an unfinished state since the collapse of the building trades business some few years ago, is now to be completed. This plant was started by Mr. Leigh Hunt, of Kansas City, who is well known in Canadian circles, and who was employed by Sir Max Aitken interests.

St. John, N. B., is preparing to enter the housing business for the benefit of the city workmen. The first step was taken at a recent meeting of the common council, when a bill giving the city power to expropriate required lands, to erect houses suitable for homes of working men, and to issue bonds to cover the cost of purchase and erection, was forwarded to the Legislature.

Mr. Jackson Booth, of Ottawa, has a large building programme for this spring. He intends to raise his new Rideau Street Building to ten storeys, and to make a six-storey structure out of the building on Sparks Street occupied by the Standard Bank, removing the present two storeys over the bank and substituting five modern storeys. Mr. Booth also intends to build on vacant property at the corner of Bank and Slater Streets

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Barrie, Ont.
It is probable that the Town's pumping plant will have to be replaced in the near future with electrically driven equipment and a standpipe constructed at the head of Bayfield Street. Engineer, J. S. Lang.

Leamington, Ont.
The Town Council propose to lay watermains on a number of streets. Clerk, R. M. Selkirk.

Ottawa, Ont.
The City Council are considering the laying of asphalt and stone block pavement on Somerset Street, at an approximate cost of $11,440. Engineer, F. C. Askwith.

Quebec, Que.
The Provincial Roads Department will commence the construction of an asphalt road between the City and Valcartier Camp as soon as weather permits. Estimated cost, $3,000 per mile. Work by day labor.

Sault Ste. Marie, Ont.
The City Council are considering the construction of a waterworks system, estimated to cost $300,000. Clerk, R. G. Campbell.

St. Cesaire, Que.
The Municipality propose to spend $3,500 on macadam roads this season. Secretary, P. Dussault.

Toronto, Ont.
The Board of Control will receive tenders until April 11th on the construction of sewers on various streets. Plans at Room 8, City Hall.

Railroads, Bridges and Wharves

Dalhousie, N. B.
The Sydney Lumber Company propose to construct a wharf and piers this sum. Manager, F. McEvoy, Dalhousie.

Saskatoon, Sask.
The City Council have had plans prepared for asphalt paving on a new concrete bridge. Engineer, J. H. Archibald.

St. Boniface, Man.
It is understood that the Municipality of St. Boniface and the City of Winnipeg have agreed as to the apportionment of the cost of the proposed Provencher Avenue bridge, and that work may proceed shortly. Approximate cost, $264,000. Engineer, W. P. Blair.

York County, Ont.
The old wooden bridge over the Humber River at Bloor Street has been destroyed, and will be replaced by a steel bridge, estimated to cost $30,000. County Clerk, W. R. Phillips, 57 Adelaide Street E., Toronto.

CONTRACTS AWARDED

Arthur, Ont.
The Township Council have let a contract for the erection of a concrete arch truss bridge to J. Kilker, Harriston, Ont.

Ottawa, Ont.
The Ottawa Electric Railway Company have awarded the contract for extensions to their tracks on Rideau Street to the United States Steel Products Company, Bank of Ottawa Building, Montreal.

Port Hope, Ont.
In connection with the construction of a bridge on Peter Street for the Town Council, the contract for cement work has been awarded to Thomas Garnett & Sons, Port Hope, and the steel work to the Petrolia Bridge Company, Petrolia.

Public Buildings, Churches and Schools

Amabel Township, Ont.
The Trustees of School Section No. 7 will receive tenders until April 29th for remodelling the school. Work will include bricking of building, erection of porch and interior alterations. Secretary, H. W. Robinson, Hepworth.

Avon, Ont.
W. Murray, Dominion Savings Building, London, is preparing plans of a school for the School Board. Estimated cost, $6,000. Red pressed brick construction.

Calgary, Alta.
Central Methodist Church, which was recently destroyed by fire, will be rebuilt. Pastor, Rev. R. Fallis.

Dauphin, Man.
Plans of a Court House, estimated to cost $80,000, have been prepared for the Provincial Department of Public Works by J. H. Bossoms, Dauphin. Tenders will be called shortly. Brick and cut stone construction.

Hull, Que.
Charles Brodeur, 63 City Hall Street, is preparing plans of a convent for the Grey Nuns of the Cross, Ottawa, Ont. Pressed brick veneer construction with limestone trimmings. Estimated cost, $18,000. Tenders may be called in about one month.

Kinburn, Ont.
Tenders on the erection of a school will be received until April 6th by the Secretary to the Public School Board. Estimated cost, $10,000. Architect, J. P. MacLaren, 104 Sparks Street, Ottawa.

Middlesex, Ont.
A. E. Nutter, Dominion Bank Chambers, London, is preparing plans of a school, estimated to cost $4,000.

Orillia, Ont.
A by-law has been carried authorizing the raising of $35,000 for the erection of a Municipal Building. Architects, Burke, Horwood & White, Ryrie Building, Toronto.

Port Arthur, Ont.
E. J. Blaquier, 200 Arthur Street, is about to start work on the erection of a school at Jumbo Gardens.

Renfrew, Ont.
The by-law to authorize the erection of a Collegiate Institute has been defeated.

Sacre Coeur, Que.
Tenders are being received for repairs to the Roman Catholic Church. Curate, Rev. L. d'Anteuil.

Simcoe, Ont.
The Board of Education will select sites and have competitive plans prepared for two schools, estimated to cost $20,000 each. Secretary, F. E. Curtis.

Smith's Falls, Ont.
The Public School Board have purchased a site for a new school to replace that recently destroyed by fire. Estimated cost of building, $30,000. Secretary, C. T. McBride.

St. Cesaire, Que.
The Village School Board propose to build a model school, at an approximate cost of $8,000, and the Parish School Board are also considering the construction of two schools, estimated to cost $3,000. Secretary, P. Dusseault.

Toronto, Ont.
The Congregation of North Parkdale Methodist Church are raising funds for the erection of a Sunday School. Work is not likely to start this year. Pastor, Rev. J. S. Speer, 112 Sorauren Avenue.

Westboro, Ont.
Tenders on the erection of a school are being received by the Secretary to the School Board. Estimated cost, $25,000. Architects, Richards & Abra, Booth Building, Ottawa. Closing date, April 10th.

Winnipeg, Man.

Reason for selling, death of owner. Apply Mrs. Anna Mae McDougall, Box 9, Wallaceburg, Ont. 14-15

Motor Squeegee Street Washer Removes Impacted Filth

A motor driven street washer that is said to clean a street as a rubber squeegee cleans a window, and which, it is claimed, will remove impacted dirt and filth in a manner impossible by ordinary methods has been put on the market by the Sterling Motor Truck Company, of West Allis, Milwaukee, Wis., under the name of the Sterling-Kindling motor squeegee street washer.

The machine consists of a special Sterling worm-driven chassis upon which is mounted a 1,000-gallon steel tank. Immediately in front of the front fenders are two flusher nozzles controlled by the driver by means of a lever. The nozzles by sprinkling the surface of the street prevent the agitation of dust, and also dampen the attached matter so that the squeegee roller can force it loose from the pavement, and wash the surface clean. Supplementing the function of the nozzles in loosening the attached matter, and to prevent the squeegee from being compelled to handle too large a mass of material, a pair of heavy pavement sweeping brooms are fitted behind the front nozzles, the purpose of which are to force aside the large refuse so that it will be suspended in the water, leaving the squeegee to wash up the tightly adhered material by frictional action. Mounted near the centre of the chassis frame, and underneath it, is a squeegee 19 inches in diameter, and 8 feet long. Each rubber spiral is easily detachable, and is mounted in a special kiln-dried wood holder of large wearing surface. The squeegee attachment is flexibly mounted and counterbalanced in such a way that when adjusted to a certain pressure, it is impossible for the roller to work loose, and the pressure against the surface of the street is uniform, the rubber strips being 6 inches deep and affording large wearing surface. A toggle joint linkage terminating in a lever in the driver's cab, enables him to easily and quickly place the squeegee attachment in and out of engagement with the street and, when returning from washing a section of street, to lift the roller out of contact with the pavement.

The tank is fitted with a water meter which indicates the amount of water flowing through it. It contains four valves near the front end for distributing water to the front and to the side nozzles near the squeegee roller.

Business Buildings and Industrial Plants

(Continued from page 45)

The Village Council are considering the installation of an electric lighting system. Clerk, Dugald McIntyre.

Boston Creek, Ont.
The R. A. P. Syndicate, Boston Creek, propose to instal a 100-h.p. motor when the power line from Cobalt is built. Manager, John Papassimakes.

Cobalt, Ont.
The Northern Ontario Power Company, Cobalt, will shortly call for tenders on the construction of a transmission line to Kirkland Lake, a distance of sixty miles. Transformers and other equipment will be required.

Easthope Township, Ont.
The installation of a hydro system is

(Continued on page 50

Power Plants, Electricity and Telephones

(Continued from page 48)

being considered by the Township Council. Clerk, J. D. Fisher, Stratford.

Galt, Ont.
A by-law to authorize the installation of an electric fire signal system at an approximate cost of $16,000 will be submitted on April 28th. Town Clerk, Joseph McCartney.

Glencoe, Ont.
The Town Council propose to obtain estimates on the installation of a hydro system. Clerk, George Wilson.

Kirkland Lake, Ont.
Tenders on the supply and installation of motors for running a day mill and compressor will be called shortly by the Buffalo Mines, Cobalt.

Vernon, B. C.
Fire Chief Moffat has recommended the installation of a fire alarm system, estimated to cost $6,000. City Clerk D. J. Tate.

Winnipeg, Man.
The Board of Control will receive tenders until 10 a.m., April 17th, for the supply of material for overhead and indoor construction, watt hour meters and three transformers for the City Light & Power Department.

CONTRACTS AWARDED

Emerson, Man.
The Town Council have awarded the contract for the installation of an electric lighting system to the Dodge County Power Company, Hayfield, Minn.

Fires

Aylmer, Ont.
Nairn Block, owned by J. J. Nairn, damaged.

Berlin, Ont.
Pavillion in Victoria Park, owned by the City Council. Loss, $6,000.

Blenheim, Ont.
Garage owned by the Springsteen Company. Loss, $16,000.

Bryson, Que.
Mining mill and store owned by the Calumet Zinc and Metals Company, totally destroyed. Will rebuild.

Dauphin, Man.
Town Hall. Loss, about $5,000.

Elmira, Ont.
Sash and door factory owned by Bauman & Letson. Loss, $10,000.

Fassett, Que.
Factory of the Standard Chemical Iron & Lumber Company. Loss, $75,000. Will rebuild.

Granby, Que.
Residence of J. Brodeur destroyed.

Halifax, N. S.
Factory owned by James Roue, 121 Lower Water Street. Loss, about $14,000.

McKay's Corner, N. S.
Residence of Hugh McPhee totally destroyed.

Montreal, Que.
Three flats belonging to Mrs. Lepailleur, 1338 St. Denis Street. Loss, [illegible]000.

Ottawa, Ont.
Residence of Edward Pieche, Rockliffe Annex. Loss, $3,000.

Port Burwell, Ont.
Livery barn owned by George Riddell. Loss, $5,000. Rebuilding is contemplated.

A. R. Wright & Sons' warehouses. Loss, about $6,000.

South Bay, N. B.
Residence of John E. Moore. Loss, about $3,000.

St. Clothilde, Que.
Sawmill owned by Omer Bergeron. Loss, $7,000. Will rebuild.

Toronto, Ont.
Office and warehouse at 77 Bay Street tenanted by Brown & Stainton, Stationers, Joss Ltd., Furriers, and L. Babayan, Rug Merchant. Loss, about $60,000.

Trenton, Ont.
King George Hotel, owned by H. Cook. Loss, $25,000.

Welland, Ont.
Residence of Fred Guido. Loss, $3,500. May rebuild.

Whonnock, B.C.
Store owned by J. H. Methot completely destroyed.

Miscellaneous

Arnprior, Ont.
Maurice Sullivan, Contractor, Harriett Street, desires to receive prices and other information with regard to all kinds of building material.

Blenheim, Ont.
The Union Natural Gas Company propose to lay an 8-inch main on Talbot and South Hall Streets. Manager, T. E. Bassett, Charles Street.

Galt, Ont.
The Town Council will submit a by-law on April 28th to authorize the purchase of a motor fire engine, at an approximate cost of $12,000. Clerk, Joseph McCartney.

Halifax, N. S.
The Halifax Electric Tramway Company, Lower Water Street, are receiving tenders on elevating and conveying machinery for their new gas plant. Engineer, H. R. Barrett, c/o the Company.

Montreal, Que.
The Miner Lumber Company, Ltd., Coristine Building, are in the market for wood-working lathes.

Ottawa, Ont.
The Works Department will purchase several tank cars of tarvia for use this spring. Engineer, F. C. Askwith.

CONTRACTS AWARDED

Ottawa, Ont.
The City Council have awarded the contract for the supply of asphalt to the Barber Asphalt Company, Philadelphia, and for brick to the Ottawa Brick Company, Castle Building.

Late News Items

Dartmouth, N.S.
Tenders on the completion of a foundry for the Williston Steel Foundry Company are being received by the Engineer, C. Hedley Williston, 504 - Robie Street, Halifax. Approximate cost, $16,000.

Dover Township, Ont.
Tenders will be received until April 11th for the erection of a church for the Presbyterian Congregation. Architect, S. G. Kinsey, 14 Fifth Street, Chatham.

Kinburn, Ont.
Tenders on the erection of a school will be received until April 12th by F. Stackhouse, Secretary to the Public School Board. Estimated cost, $10,000. Architect, J. P. MacLaren, 104 Sparks Street, Ottawa.

London, Ont.
The Board of Control have awarded the contract for laying 52,000 square yards of asphalt pavement to the Standard Paving Company, Central Chambers, Ottawa, at $104,000.

Nassagaweya Township, Ont.
S. B. Coon & Son, Ryrie Building, Toronto, will receive tenders until April 8th for the erection of a school, estimated to cost $5,000.

Niagara Falls, Ont.
The general contract for the erection of an addition to the Bank of Hamilton, Queen Street and Erie Avenue, has been let to John Blair, Morrison Street, the painting to J. Smith & Sons, 168 Ontario Avenue, and the plumbing and electrical work to the Niagara Electric Company, Niagara Falls South. Approximate cost, $15,000.

Quebec, Que.
Tenders will be received until 4 p.m., April 11th, by the Secretary to the City Council for the supply of between 2,000 and 4,000 feet of fire hose, battery zincs, sulphate of copper and waterproof wire. Specifications at office of the Fire Department.

Sault Ste. Marie, Ont.
Tenders on the erection of a power and pumping station will be received until 5 p.m., April 10th, by the City Clerk. Estimated cost, $15,000. Engineer, A. E. Pickering.

Toronto, Ont.
The general contract for the erection of a machine shop for Whitfield & Company, 33 Sherbourne Street, has been awarded to Davidson & Company, 188 Duke Street, and work has been started. Approximate cost, $12,000.

A. R. Clarke & Company, 633 Eastern Avenue, are receiving tenders on the erection of a workshop, estimated to cost $30,000. Concrete, steel and brick construction.

The Board of Education will receive tenders until April 11th on the supply of four motors for the Technical School, Lippincott Street. Plans and specifications at Principal's Office.

Tenders on the supply of field paint for the Bloor Street Viaduct will be received until April 11th by the Board of Control. Specifications at Room 12, City Hall.

Tenders will be received until April 11th by the Board of Control for quantities of asphalt, brick and bitulithic pavement and concrete curbs and sidewalks. Specifications at office of the Works Department, City Hall.

Chicago Issues New Rules for Sewer Trenching

Utilities in the space to be occupied by sewers in Chicago are subject to new rules recently put out in standard specifications by the board of local improvements of that city. The principal features of interest to contractors relate to trenches dug by excavating machines and are as follows:

Utilities in the way of trench machines of the steam-shovel type used to excavate for a sewer 3 feet in diameter, or larger, must be removed and replaced without expense to the contractor. This diameter is reduced to 24 inches when machines of the endless-belt type are used. Below 24 inches the utility must be left in place and maintained at the expense of the contractor. Utility companies must take care of their lines when rock is to be blasted, provided five days' notice is given.

Where sewer trenches are excavated without the use of excavating machinery, except in rock, all utilities will be left in place and maintained at the expense of the contractor.

In paved streets utility companies must replaçe disturbed pavement areas outside the limit of the sewer trench.

Service lines, except water services, to buildings, must be removed without expense to the contractor on 48 hours' notice, when excavating machines are used, also all interfering aerial equipment must be removed or altered. The latter, however, will not be removed to accommodate backfilling machinery, except at the expense of the contractor. Somewhat similar rules are in effect with reference to water mains.

Bad Management of Toronto-Hamilton Highway

THE Board of Control of the city of Toronto have taken the only possible course in agreeing to recommend the payment of an extra hundred thousand dollars to complete the Toronto-Hamilton highway. It would be exceedingly unwise to hold this work up at the present time when it is two-thirds completed and equally unwise to revise the original plans to the extent of saving money by constructing an inferior roadway. The whole scheme has apparently been badly managed, conceived in ignorance and carried forward in a way that these same men would never dream of handling their own private affairs. The management of this work, by the commission entrusted with it, is open to the gravest censure and road building in Ontario has been discredited to such an extent that it will take years to recover. The only ray of sunshine in the whole matter is that the province has learned its lesson and will know in future where not to look for highway commissioners. However, when we get in a hole there is nothing to do but get out of it as best we can and we are entirely in accord with the idea that this roadway should be completed as early as possible and that it should be built as permanently as the best engineering practice teaches us how to build it.

In censuring the mis-management of this commission, however, we must not overlook the fact that when the roadway is completed, expensive though it may be, we shall have fair value for money expended. It will be a good road, located where a good road is needed. That will always be some satisfaction to the people who paid for it, although they would not have built it, just now anyway, if they had been given full information in the first place. We hope the province will be able to live down the impression that has generally (and naturally) gone abroad that the cost of good roads is a gamble. Nothing could be farther from the facts. There is no doubt that if proper engineering advice had been sought the cost could have been determined beforehand to within a few hundred dollars. That this was not done probably merely indicated the unbusinesslike attitude of the commissioners.

Whether the lack of proper information was deliberate or simply due to a credulity born of enthusiasm we trust the province has paid a sufficient price for their experience, so that in our road work of the future we shall obtain definite advice on two points before committing ourselves to large expenditures, (1) the cost of the work shall be carefully figured by engineers of ample experience and facilities for learning all the conditions and, (2), the men who have been responsible for the mismanagement of the present work shall never again have a chance to get us into such a mess.

Should We Stop Recruiting in Ontario?

To the Britisher, to the Canadian, there is something repulsive about the word "conscription." Voluntary service has been so long recognized throughout the British Empire as the ideal form of military law that we do not take kindly to the thought of being compelled to shoulder arms. But in the face of what is happening in Canada, if we look right at the facts we cannot but feel that there is much to be said in favor of conscription.

What is the situation in Ontario? Recruiting has been carried on to such an extent and in such a haphazard manner that our industries are crippled, production is at low ebb, labor for the factory is unobtainable, and contracts which rightly belong to us are going to the United States. Ontario is suffering as the result of her activity in recruiting, a statement which cannot be made of certain other provinces of the Dominion. Conscription would remedy this inequality.

This war is a business and should be conducted in a businesslike way. Have we not recruited beyond the requirements? If we have not, why are battalions which were in camp at Niagara last year preparing to return there this summer? The time necessary to train a soldier is surely not a satisfactory answer—and all the time our industries crying for men.

Sir Robert Borden offered to send 500,000 men if required, but it would seem that the Minister of Militia's call for the second 250,000 has not yet been justified.

If we are recruiting more men than are required, it means a loss to the country and to the Empire. Every man's time should, in this crisis, be employed where it will be most effective.

The scarcity of labor is serious. The suggestion has been made that women take the place of men in the banks and offices and other business places, and that the men thus replaced who do not join the colors go to the farms. Yet in the face of this situation we find the Government appropriating $100,000 for a campaign in the daily newspapers to encourage increased production and thrift on the farm, where the supply of labor is already totally inadequate. There are grave economic problems before us. Can they be satisfactorily worked out under the present system of recruiting? What are the opinions of our readers?

The Brick Industry

What's the matter with the brick industry? This question has been raised very frequently of late, yet no one manufacturer seems prepared to say just what the reason is for the slump in the demand for brick as a building material, but each is willing to say what has happened in his own locality.

Brick today are fully 25 per cent. less than before the outbreak of war, while many other building materials have advanced, or remained constant in price. Lack of organization among brick manufacturers may be cited as the real difficulty in the brick industry—"United we stand; divided we fall" seems to be apt and timely.

Mr. W. B. Wreford, in a paper before the National Brick Manufacturers' Association, published in this issue unreservedly tells the brick manufacturers to pull together—advertise, create a demand for brick, and the price will very shortly adjust itself. He advocates a National Building-Brick Bureau to encourage advertising on the part of the brick manufacturer, to assist in preparing advertising material and in directing the lines of exploitation work, and to collect and furnish specific data for its members that would be of value in the promotion of brick as a building material against all competitors.

Speaking on the organization of the cement and lumber industry, Mr. Wreford quotes figures to show the annual expenditure in publicity campaigns spent each year by these industries. As a result the field of cement and lumber is world-wide, while that of the brick industry is usually confined to local communities where brick is manufactured. The cement industry has a department whose function it is to furnish such data as architects may require for their consideration of reinforced concrete, and to lend such aid as may be desired in preparing designs in which the reinforcing is very detailed. Such information is given free.

This seems to be the solution to the question—be alive, get together, create a demand, make people talk brick then they will buy and use it.

Toronto Branch C.S.C.E. to hold Luncheon

The Secretary of the Toronto branch of the Canadian Society of Civil Engineers, Mr. L. M. Arkley, has mailed the following notice to members:

The regular monthly meeting of the Toronto Branch of the Canadian Society of Civil Engineers will be held in the Chemistry and Mining Building of the University of Toronto on Thursday, April 13th, 1916. Professor A. P. Coleman, Ph.D., will give an illustrated address on "A Visit to the Mountains of Northern Labrador." Come and hear this very interesting address.

The executive of the Toronto Branch propose holding a luncheon at the St. Charles Hotel on Thursday, April 27th, inst., at 1 p. m., if we are assured of a sufficient attendance to justify our getting a good speaker for the occasion. Please state on the accompanying card if you will be able to attend, and return to the Secretary at an early date.

We have been asked by the Secretary of the Canadian Society of Civil Engineers, Prof. C. H. McLeod, to ascertain the names and standing of as many prospective members as possible in the vicinity of our Branch. Each member is therefore requested to return a list of such names to the secretary of the branch as soon as possible. Your prompt and hearty co-operation in these matters will be much appreciated.

Barge Replaces Trestle in Making Rock Fills at Halifax

By using a dumping bridge supported between the end of the fill and a large scow by an A-frame boom, the difficulties of building a trestle on rock bottom and maintaining it while making a rock fill have been avoided in constructing the Halifax ocean terminals in Nova Scotia. The stringers of the bridge are of timber, and are suspended from the A-frame at the centre of the bridge on the same principle as is used in swinging the gang plank of the familiar river steamer. Two 18-yard side dump cars at a time can be dumped from the bridge into clear water between the barge and the end of the fill. In order to save switching, the track extends the full length of the barge to accommodate four cars that have been dumped while the fifth and sixth are dumping. Thus the only loss over operation on a trestle is that the whole train cannot be dumped simultaneously. This is more than made up by saving the time and expense of building and maintaining a trestle on rock bottom in 30 to 60 feet of water.

The fill for the breakwater has been finished, that for the centre of pier B is now being completed, and that for the centre of pier A will be made in this way. All three are long, narrow fills built out from the end. Material from a heavy cut on the railroad approaching the terminal, for which the Cook Construction Company and Wheaton Brothers are contractors, is being used.—Eng. Record.

The Engineer at the Front

The Ottawa branch of the Canadian Society of Civil Engineers, are holding their fourth luncheon for the season at the Ladies' Cafe, Chateau Laurier, on April 13 at 12:45. Lieut.-Col. Melville, O. C. Engineering Training Depot, Ottawa, will address the members on the subject: "With an Engineer Battalion at the Front." Lieut.-Col. Melville has just returned from active service to assume charge of the Engineer Training Depot at Lansdowne Park in the city of Ottawa. He will describe the work and duties of the Engineer Forces at the front.

The cost of street cleaning at Victoria, B. C., is now 13.4 cents per 1000 sq. yd. This does not include plant rental and overhead charges. All the work is done with hand brooms, pick-up carts and cans. No flushing water is used.

Shall I Build Now, or Wait? Comparative Prices Today and at Outbreak of War

[Continued from April 5]

In our last issue we printed the first of a short series of articles which have for their object the publication of information which may enable the prospective builder, the architect or the general contractor, to compare the cost of building to-day with the cost a year ago or at the outbreak of the war. We discussed in that article more particularly the elements that enter into the initial stages of the ordinary building—stone, brick, cement and lime. Our figures for these items pointed to a considerable reduction in price, twenty-five per cent., and over in the case of brick and averaging anywhere from ten to twenty per cent. decrease. So far as these materials go to make up a building, therefore, it is less expensive to build today than it was at the date of the outbreak of war.

Just to what extent these four items enter into the cost of a building depends, of course, on the type of construction. In a steel structure it would be much less than in an ordinary brick dwelling or a factory or warehouse built chiefly of brick or cement, or both. Brick being the material that has shown the greatest decrease in price, it follows that those buildings that use a maximum of brick will profit the most by present conditions. In a residence, for example, where the cost of the brick alone may run from 15 to 20 per cent. of the total cost, the saving should be very considerable.

Labor

We must not overlook the important place occupied in this discussion by the item of labor cost. Generally speaking it probably would not be too liberal an estimate, on the average building contract, to allow one-third for the cost of the labor, as compared with two-thirds for material laid down at the job. For the purpose of argument anyway this estimate is near enough. Carpenter labor would run nearer one-half; painting, tinwork, etc., still higher. Now what is the condition with regard to labor?

It may truthfully be argued that labor is scarce, but equally truthfully that building work is scarce. The war, so far as the workman who has stayed at home goes, has been a godsend in sidetracking what would otherwise have been one of the most troublesome labor problems of recent years. Even at the moment it is by no means proven that there is a shortage of labor for such building work as there is in hand. For example, it was announced only the other day that twelve per cent. of a certain trade had responded to the call to arms. This still leaves 88 per cent. to attend to construction work that does not run to more than half, and in many cases to not more than ten per cent. of what was going forward three years ago. Many of these men have, of course, changed their occupation, but it is not characteristic of a mechanic to want to do other work than his own except under compulsion. The result is that labor to-day in very many lines of the building trades is easier to get than it was a year or two before the war and consequently costs less. A comparison between labor costs to-day and at the outbreak of war probably shows that wages have advanced but slightly. The labor market, however, is uncertain and subject to influences from the United States. It does not appear that the removal of a half million men from this continent should cause any serious shortage in mechanics, though it may cause us a little temporary delay and inconvenience.

Lumber

The other big item is lumber, under which mill-work is generally included. Lumber, not including carpenter's wages, usually accounts for somewhere between 15 per cent. and 20 per cent. of the total cost of a private residence. In a factory it may be less, in an office building more, all depending on the individual requirements. Lumber prices shortly after the war broke out showed signs of weakening, but it seems to be a fact that the lumbering trade, though they do not deal to any great extent in war materials, have been able to adjust their business to conditions with a fair degree of satisfaction to themselves. The result is that prices to-day are about the same or slightly in advance of what they were in August, 1914, though still considerably less than in the boom years of 1912-13.

Mill-work stands in about the same position as lumber—slightly advanced over prices of two years ago. The future of mill-work prices is dependent to a more considerable degree on labor conditions, material being a less important item.

However, though both of these items are inclined to show slight increases it must be taken into consideration that contractors are eager for contracts today and willing, rightly so, we believe, to accept work at actual cost so as to be able to take care of their overhead and keep their organization together. This may, or may not, offset the increase in the price of lumber and mill-work. We are inclined to think it would.

(To be continued)

Irrigation Dam

Arrowrock Dam, in Idaho, is the key to an irrigation system that is transforming 234,000 acres of barren sagebush desert—adjacent to Boise, the State capital—into fruitful gardens, orchards and farms. By throwing a dam across a gorge in the canyon twenty-two miles above the city the channel of the river is converted into a reservoir running back eighteen miles into the mountains. It holds, when full, 244,000 acre feet of water, enough to cover 381 square miles to the depth of one foot. It will reclaim 234,000 rich acres in the Boise Valley. Arrowrock is the highest dam in the world to-day, 348.5 feet from the low point in the foundation to the sixteen-foot driveway over the top. It is 240 feet thick at the base and 1,060 feet long. The great mass is below the bed of the river; it was necessary to go down 91.5 feet through volcanic rock to reach a solid foundation in granite. In its construction 530,000 cubic yards of concrete were used.

The Department of the Interior, Ottawa, have just issued a report of the progress of stream measurements (hydrometric surveys) for the calendar year 1914, prepared under the direction of F. H. Peters, Commissioner of Irrigation, by P. M. Sander, chief hydrometric engineer, assisted by G. H. White and G. R. Elliott.

Dale Presbyterian Church, Toronto

The "Roofless" Church finally becomes one of Toronto's most beautiful edifices — Capacity 2000 — Cost $90,000

THE culmination of seven years of unceasing endeavor and self-sacrifice by the Rev. J. D. Morrow and his congregation came on Sunday, April 2nd, when the new Dale Church was dedicated and the "roofless church" became a thing of the past.

In 1873 "New" St. Andrew's Church, King Street, started a mission on the then outskirts of the city, at King and Tecumseh Streets. In 1889 this small wooden structure, known as St. Mark's Mission, was moved to one side and St. Mark's Church, a plain red building, became the house of worship. At first St. Mark's was not very prosperous, being situated in a district where honest poverty was the rule and prosperity the exception. But in 1905, with the advent of the Rev. J. D. Morrow, things brightened so considerably that in 1908 the condition of affairs proved the dire necessity of a larger church.

Robert F. Dale, a retired baker, and a member of St. Mark's for some years, showed his appreciation of Rev. J. D. Morrow's work by giving the present site at the corner of Bellwoods Avenue and Queen Street to the congregation. The old building was sold and on July 24, 1909, the first sod of the new site was turned.

"Pay as you go" was the principle upon which the Rev. J. D. Morrow insisted, and the "going" was no faster than the "paying"—which was pretty slow. But J. D. Morrow never wavered; he worked on with faith and persistence ably supported by his congregation, and his efforts were finally rewarded in the dedication of the new church last week.

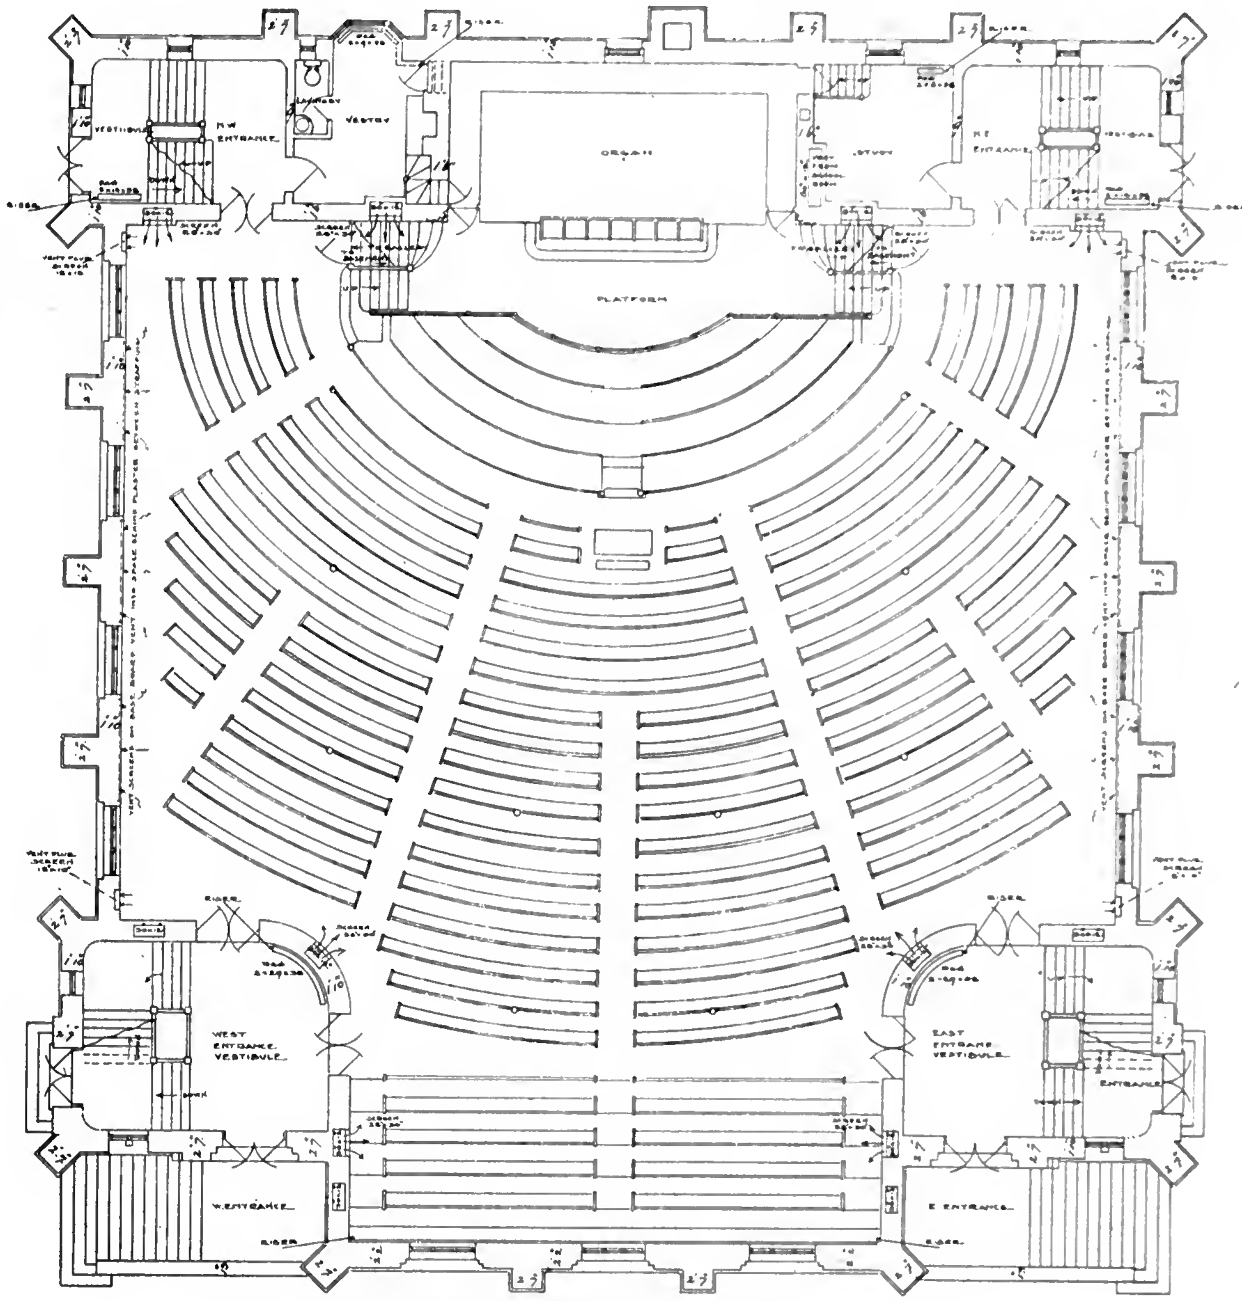
The church is situated on the corner of Queen Street and Bellwoods Avenue, fronting on Queen Street. Entrance is made through two large entrance vestibules in the south-east and south-west corners, and through two side vestibules in the north-east and north-west corners. The main vestibules have double entrances—one off Queen, and one on a side street.

The church, which is 90 ft. by 106 ft., is in the Perpendicular Gothic style, built of brick for the main body, with stone for the Sabbath school, the whole being set on concrete foundations. Difficulty was experienced with the foundations, which were laid in 1909, the western portion of the site being composed of artificial fill over boggy ground. This necessitated sinking the foundations very deep to procure a good bearing. The east side of the site, however, was good clay, necessitating only a relatively shallow foundation. The foundations cost approximately $2,000.

Auditorium

The auditorium, or church proper, has a seating capacity of 1,700—probably the largest percentage per square foot of floor space of any church in Toronto. One of the special features that attracts the attention is the fan-shaped choir loft, situated in front

Fig. 1—Dale Presbyterian Church, Queen St. and Bellwoods Ave., Toronto.



AUDITORIUM·FLOOR·PLAN

Fig. 2 —General Floor Plan Auditorium, seating capacity 1700.

of the platform. The latter, 44 ft. by 10 ft., is accessible on both sides from both the auditorium floor and the gallery.

The organ loft is directly behind the speaker's platform, and is closed in by an artistic open screen. This screen work is backed in the lower larger arches by heavy curtains, and in the upper smaller ones by bronze netting and entirely excludes all view of the organ pipes. The screen is artistically decorated and streaked with gold, adding materially to the beauty of the church.

The vestry on the west side of the organ loft is about 12 by 12 ft., and is completely fitted with all modern conveniences. On the east side is a similar room used for a study. Another special feature has been installed at the back of the auditorium where the space between the main vestibules under the gallery can be completely closed off by means of rolling doors and used as a prayer room or baptistry. The same system has been adopted in the Sabbath school below. The gallery extends completely around the auditorium, and is accessible from the main entrance vestibules, the side entrance vestibules, and from the choir loft. It is supported by marble pillars with ornamental cappings, and faced with an oak railing.

The floor of the auditorium is reinforced concrete supported by pilasters, and is probably the only one of its kind in a church in Toronto. It has a slope of between 4 and 5 feet front to rear, and is covered with ⅞-in. oak flooring. The interior trim and fittings throughout the church are oak. Special attention has been given to the design of the pews, which are most comfortable. Individual choir chairs have been provided in the choir loft.

Acoustic Properties

The roof of the building is a steel truss, with probably the largest unsupported span of any Canadian church, being 90 ft. between walls. The steel work is entirely closed in, and the decorated ceiling presents an even, unbroken surface, free from any obstructions, which has made possible the remarkable acoustic properties of the church. With the exception of ten small marble pillars supporting the gallery, there are no obstructions of any kind in the church, which is probably unparalleled in Toronto for the remarkable ease with which the speaker can be heard in any corner of the building.

capacity of 1,000. Above the vestry and study rooms, on the gallery floor, are two choir rooms, and above these, across the whole north end of the building, are large recreation rooms and work rooms for young men, and across the south end similar recreation rooms and committee rooms for young women.

The church was designed by Herbert G. Paull, architect, 395 College Street, Toronto, and was built by E. T. C. Poole. The building was constructed by day labor, at a total cost, including material, of $90,000 —financial matters being left in the hands of the architect. Sub-contractors on the work were: concrete foundations and reinforced floors, John Leach & Company; stone work, Cement Products; steel, Hepburn & Disher; brick, Walker Morley; plaster, Balmer & Blakely; interior decorations, Doxee; windows,

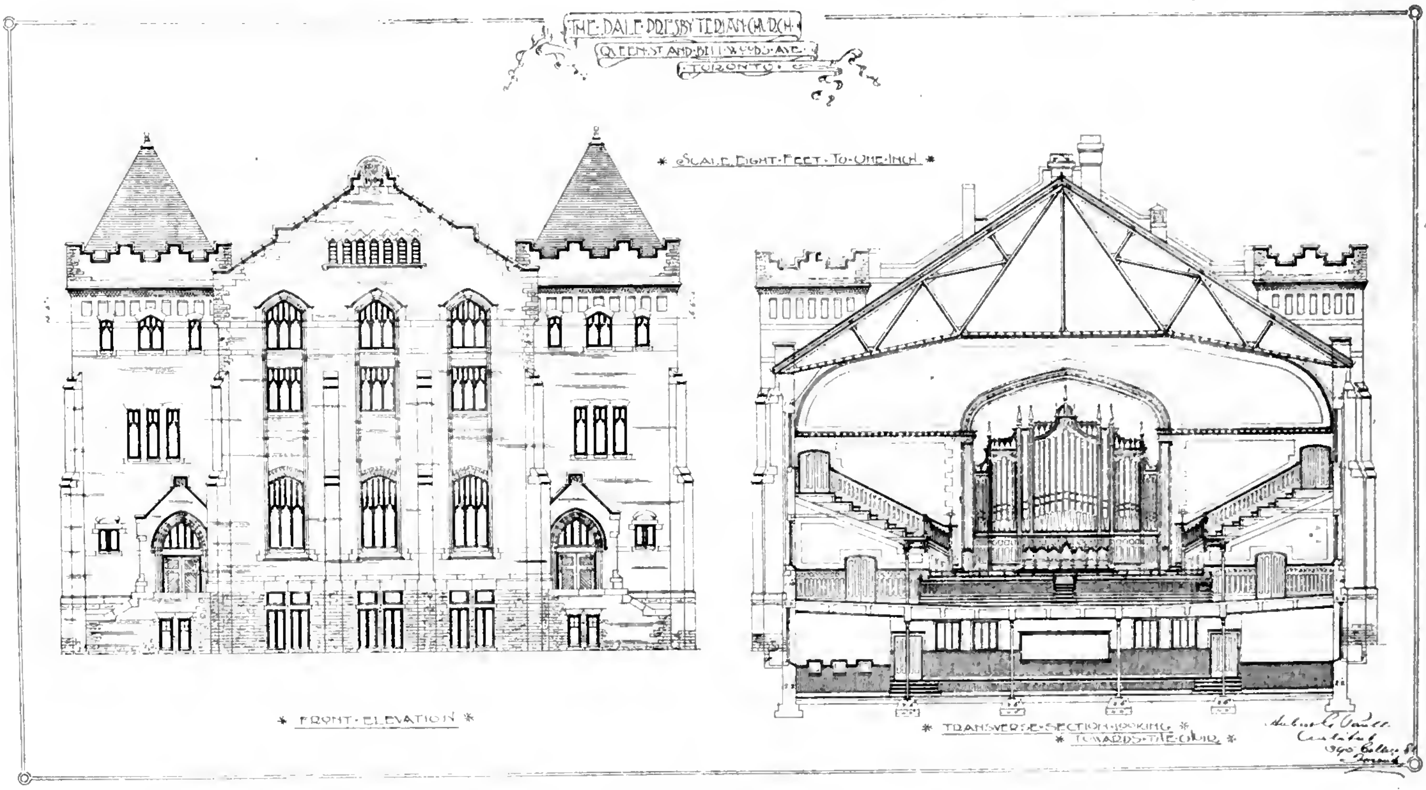


Fig. 3—Queen Street Elevation and Section, showing choir and organ lofts, also section of roof-span.

The steel roof is covered with asbestos shingles. Steel lath is used throughout, and the windows are leaded art glass with cut-stone sashes. The stairs are of fireproof, iron construction, with mastic treads.

Light and Ventilation

Every attention has been given to the lighting, heating, and plumbing. Semi-indirect lighting is used in the auditorium, light being diffused uniformly from forty-five suspended indirect lights. Heating and ventilation is by hot air heated by direct steam; cold air is drawn in by a large fan, heated, and distributed throughout the building through openings in the walls and ceilings, foul air being drawn off by automatic ventilators. A complete change of air is effected every ten minutes.

The church is finely and beautifully decorated in soft, pleasing tints—bright, yet not gaudy—providing a sense of restfulness and comfort.

Other Features

The Sunday school in the basement, which has been used in the meantime as a church, has a seating

Queen City Glass Company; lighting fixtures, Knight Brothers; iron stairs, Ever Hardwood Company; mastic treads, Johns Manville; rolling doors, Watson Smith.

The buying movement in structural steel is now probably greater than it has been at any time since 1906. According to a Pittsburgh press dispatch contracts for fully 500,000 tons of this material were pending last week. Bridge contracts placed in February were the largest in a single month for the last six years, and it is expected that the tonnage ordered in March will be even larger than that of the previous month. The steel industry is having the greatest period of prosperity in its history.

In the Contract Record of March 29 we printed a brief description, with illustration, of a new expansion joint recently placed on the market by the Barratt Company of New York. This material may now be obtained from the Paterson Manufacturing Company, Limited, of Toronto and Montreal.

The Determination of the Physical Properties of Road-Building Rock

By Provost Hubbard and F. H. Jackson, Jr.*

It is now generally recognized that any stone, to be suitable for use in macadam construction, must possess to a certain degree, depending on circumstances such as character of traffic and method of construction, three distinct physical properties, which may be briefly defined as follows:

(1) Hardness, the resistance which a rock offers to the displacement of its surface particles by abrasion;

(2) Toughness, the resistance which a rock offers to fracture under impact;

(3) Binding power, the ability which the dust from the rock possesses, or develops by contact with water, of binding the larger rock fragments together.

Of these, the first two are of particular interest from the standpoint of the present discussion, and they may be very briefly described as follows:

The degree of hardness of a rock is determined by what is known as the Dorry method. It consists essentially of subjecting a cylinder, 25 mm. in diameter, of the material to be tested to the abrasive action of crushed quartz sand fed upon a revolving steel disc, against which the test specimen rests. The end of the specimen is ground away in inverse ratio to its hardness, so that the hardness may be computed by determining the loss in weight after any given number of revolutions of the disc. The coefficient of hardness discussed later is obtained by subtracting one-third of the loss in weight in grams from 20, after 1,000 revolutions of the disc.

Toughness

The degree of toughness is determined by the Page impact method. A cylinder 1 in. in diameter and 1 in. high, cut from the rock specimen, is subjected to the impact caused by the free fall of a 2-kgm. weight dropped from successively increasing heights until the energy of the blow is sufficient to fracture the test specimen. The test consists of a 1-cm. fall for the first blow, followed by falls increased by 1 cm. after each blow until failure occurs. The height from which the weight drops when failure takes place is used as a measure of the toughness of the material.

Since the establishment of the road-material laboratory by the United States Government, upwards of 3,000 samples, representing every known variety of road-building rock, and obtained from every State in the Union, as well as from foreign countries, have been subjected to the tests outlined above. The results of these tests are plotted in graphic form, in a curve in which the coefficients of hardness are plotted as abscissae and the factors of toughness as ordinates. Small circles represent the corresponding hardness and toughness of an individual rock sample. Large circles represent the average of all the coefficients of hardness for each value of toughness. Hardness values range from 0 to 20 and toughness values from 1 to 47.

A study of this curve brings out the following points:

(1) That the average toughness for all tests made is about 9.

(2) That the average hardness increases with toughness, and that the rate of increase becomes less as the toughness values become larger.

(3) That individual values of hardness vary through wide limits for low values of toughness, and that the variations from the average decrease uniformly with the increase in toughness up to a certain point, about 20, after which they remain constant with very little variation from the average.

(4) That, when any given value for toughness falls within certain limits, which define the suitability of the material for macadam-road construction under different traffic conditions, the corresponding value for hardness will fall within similar limits for hardness.

The first three facts are clearly indicated, but in order to substantiate the last deduction it will be necessary to define the limiting values of hardness and toughness which experience has shown should be applied when judging the fitness of stone for use in macadam construction under different traffic conditions. Such limiting values for toughness are shown on the curve in the ordinates at 4.5, 9.5, and 18.5, and the corresponding limiting values for hardness at 10, 14 and 17. In other words, after making all allowances for variations due to local conditions, it may be fairly assumed that stone for use under light, horse-drawn, steel-tired vehicles should show a toughness of from 5 to 9 and a hardness of from 10 to 17; for moderate traffic a toughness of from 10 to 18 and a hardness of over 14, and for heavy traffic a toughness of 19 or over and a hardness of 17 or over. The terms "light," "moderate" and "heavy" in this connection refer to the total volume of traffic upon the road, calling, say, under 100 teams a day "light," 100 to 250 "moderate," and over 250 "heavy."

Practically all the values of hardness shown in the figure are above the various lower limits set by the best water-bound macadam-road practice.

For light traffic conditions, 94 per cent. of all the samples tested have a hardness of more than 10; for moderate traffic, 95 per cent. have a hardness of more than 14; and for heavy traffic, 94 per cent. have a hardness of more than 17.

Light Traffic

A large number of hardness tests appear above the upper limit of 17 set for light traffic conditions. Although on its face this would indicate that a determination of the hardness is necessary in this instance, reference to test records show that by far the greatest number of these tests (about 75 per cent) are on granites, quartzites, and hard sandstones, which are unsuited for use in the wearing course of water-bound macadam roads, owing to their lack of binding power, as shown by actual test.

Finally, the results of 2,500 individual routine tests made by the Office of Public Roads and Rural Engineering show that for practical routine work the hardness test adds nothing to our knowledge of the value of any particular rock sample for use in water-bound macadam-road construction over that obtained from the toughness test.

While the binding or cementing value of a rock is a most important consideration from the standpoint of

* Respectively Chemical Engineer and Assistant Testing Engineer, United States Office of Public Roads and Rural Engineering in Surveyor.

ordinary macadam construction, the same is not true of broken stone roads which are surface treated or constructed with an adhesive bituminous material. The hardness of the rock is also of relatively less importance, owing to the fact that the fine mineral particles produced by the abrasion of traffic combine or should combine with the bituminous material to form a mastic, which is held in place and protects the underlying rock from abrasion so long as by proper maintenance it is kept intact. The toughness of the rock, however, is of more importance, as the shock of impact is to a considerable extent transmitted through the seal coat, and may cause the underlying fragments to shatter. It would therefore seem that the minimum toughness of a rock for use in the construction of a bituminous broken stone road, or a broken stone road with a bituminous-mat surface, should for light traffic be no less than for ordinary macadam subjected to the same class of traffic. For moderate and heavy traffic, however, the same minimum toughness may probably prove sufficient, owing to the cushioning effect of the bituminous matrix. No maximum limit of toughness need, however, be considered for any traffic.

In the case of bituminous concrete roads, where the broken stone and bituminous material are mixed prior to laying and consolidation, it would perhaps appear advisable to set a minimum toughness of 6 or 7 for light traffic roads instead of 5, in order to insure against the possibility of the fragments of rock which have been coated with bitumen being fractured under the roller during consolidation, and of 12 or 13 for moderate and heavy traffic, instead of 10 and 19, as in the case of water-bound macadam roads.

For broken stone roads which are to be maintained with dust palliatives, it would appear that the same limits of toughness should hold as for ordinary macadam.

For easy reference the following limits of toughness are given in Table 1, as representing facts developed in the foregoing discussion. It is, of course, quite probable that these limits will require modification as the correlation of laboratory tests to service results becomes more perfect.

TABLE I.

Limits for toughness for rock used in the construction of broken-stone roads.

Type of road.	Light traffic. Minimum.	Light traffic. Maximum.	Moderate traffic. Minimum.	Moderate traffic. Maximum.	Heavy traffic. Minimum.	Heavy traffic. Maximum.

New Monnoyer Type of Cement Block Chimney at Quebec

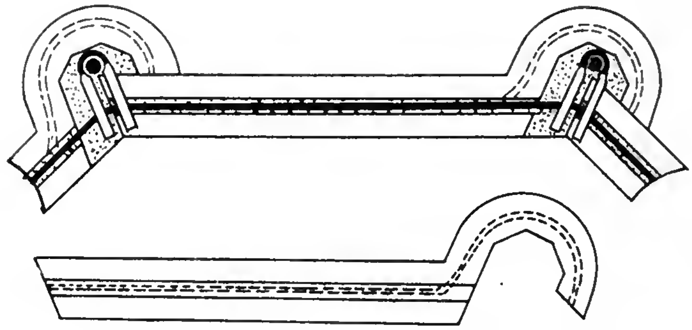
A contract for a new cement block chimney for the Monastery of the Franciscan Fathers, Quebec, was recently awarded to Eduoard Pelletier & Fils, Quebec. The chimney will be 65 feet in height above the ground level, with an inside diameter at the summit of 2 ft. 6 ins., and at the base of 5 ft. 3 ins. Foundations for the chimney will be carried down to rock, about 5 ft. below the ground level. The flue opening will be above the ground level, and will be 3 ft. high by 2 ft. 6 ins. wide, to be built of reinforced concrete. The vertical reinforcing rods of the foundation will be extended into the footing almost to the base, and will be continued above the substructure, overlapping and bonding with the vertical reinforcing of the substructure for four or five feet.

The shaft of the chimney is to be constructed on the Belgian "Monnoyer" system. Blocks are cast ten inches in height, for average diameters, with a hook or hollow projection at one end, as shown. The opposite end is tapered at an angle fixed by the diameter of the chimney and the number of blocks per course. Blocks are cast in a steel form, being mixed rather dry, and on removal from the form are sprinkled regularly for about a week before being used in construction. Blocks are reinforced horizontally, as shown in the lower cut, and are moulded with a horizontal groove on the top face, in which horizontal reinforcement is laid every course.

The method of erection is to place a course of blocks, the number of which vary according to the diameter of the chimney, the blocks being set with the hook around the vertical reinforcement, and the square end set into the head of the adjoining block, as shown. The head room is sufficient to allow considerable latitude in setting to permit of adjustment in the diameter of successive courses, thus making it possible to obtain a conical shape, which is so much more desirable than the cylindrical form.

The operation of erecting is effected very rapidly; masons working in the interior of the chimney, receive their blocks ready to lay, put them in place, mortar the 10 inches in the interior of the rib, prepare the joints for the new blocks, and continue very rapidly to lay them.

The chimney will be terminated at its summit by two bands of specially constructed blocks and a cast iron coping.



Monnoyer Type of Cement Block—Showing shape of block and manner of laying.

The concrete for the blocks consists of a 1-2-4 mixture and is placed in the steel forms in a semi-dry state, the reinforcing rods inserted and the whole well tamped. For the mortar forming bonds between the blocks, a mixture of one of cement and two of sand is used. The chimney will be lined inside with 4 ins. of fire brick set in fire clay, to a height of 15 feet below the smoke flue. A sectional steel ladder will be built up along with the erection of the chimney, the supports being tied into the vertical reinforcing rods.

Aerial Cableway over Niagara River

Torres System of Constant Tension Steel Cables Supports a 46 Passenger Car over Whirlpool Rapids — Cost $60,000

A NEW scenic pleasure device in the form of an aerial cableway over the Whirlpool Rapids, Niagara River, has recently been completed at Niagara Falls, Ont. The span is said to be the longest in the world, being approximately 1,800 feet. The Niagara whirlpool is about three miles below the Falls, and is almost entirely in Canadian territory. The cableway has both anchorages within the province of Ontario; yet it crosses a point in the boundary line, and for that reason international consent was necessary for the promotion of the project. The cableway, which is based on a Spanish patent, was built by the Niagara Spanish Aerocar Company, Limited, Gonzolo Gorres y Polanco, C.E., chief engineer and vice-president of the company, to whom we are indebted for the following information.

Anchorages

The design of the anchorages, both of which are on the Canadian side, one at Colt's Point and the other at Thompson's Point, was governed largely by the fact that the cableway was not allowed to cross the tracks of the Niagara Belt Line Railway, that the appearance of the cliffs on neither side of the whirlpool should be altered and that no towers or structures should rise above the level of the track of the railway which runs along the cliff.

The passenger car is suspended from a running gear which travels on six parallel track cables of 1-in. crucible steel rope. Each cable is anchored securely at Colt's Point by means of a 2-in rod bent into an anchorage in a 740-ton concrete block. At the other terminus each track cable passes over a sheave and is fastened to a counterweight or stretcher. Boxes 12 ft. high by 6 ft. 7 in. wide by 11 in. deep, made of riveted steel, contain cast-iron weights sufficient to make a total of 10 tons for each track-cable counterweight.

Each track cable is entirely independent of the others. The breaking of any one of them would not be serious, as the other cables would support all the weight of the car without any increase in their tension. The car would drop several feet suddenly, and, after a few vertical oscillations, would assume a new position of equilibrium.

Thus, the breaking of one cable does not imperil the passengers, and the breaking of two cables at the same time would be nearly as improbable as the simultaneous breaking of two cables belonging to totally separate installations.

Central Tension System

The simplicity and safety of this system lie in the fact that each cable is put into fixed tension from the start of operations, that this tension never varies, that the resistance of the cables can be verified at any time by increasing the load on the weight boxes, that if any cable or fastening is faulty it will probably break when heavily weighted for trial or inspection trips, and that if a cable does break practically no extra strain is put upon the other cables.

The car built for Niagara provides seats for 24 passengers, and standing room, in a raised aisle in the centre of the car, for 21 more, besides the conductor. The weight of the car empty is 3½ tons, fully loaded 7 tons. It is 10 ft. 10 in. wide, 24 ft. long and 23 ft. high. It was manufactured complete in Spain, and assembled here.

The car is propelled by a ⅞-in. 6 x 19 plow steel traction cable, fastened to one end of the car. This cable passes over a sheave on Colt's Point, runs back across the Whirlpool, over a sheave in front of the Thompson's Point station, and to the driving sheave. From here is passes around three sheaves, to one of which is fastened a 10-ton counterweight box, arranged in guides similarly to the track cable counterweights, and this creates a tension in the cable which adjusts any slack caused by the rising and falling of the car. After passing around another groove in the driving sheave, the traction cable passes out to the other end of the car.

Motive Power

The 8-ft. driving sheave is turned by a 75-h.p., 3-phase, 440-volt, 480 r.p.m. Westinghouse motor, through a 30 to 1 Hindley worm gear, giving a speed to the car of about 400 ft. per minute when the controller is at full speed. The trip can be made in about

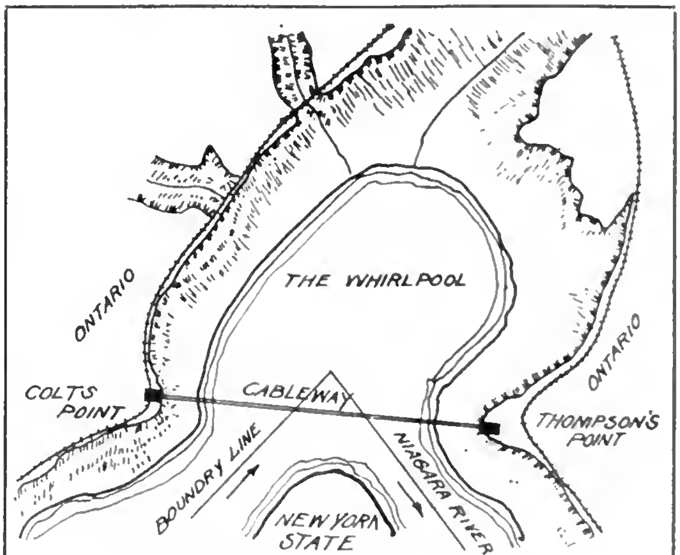


Fig. 1 Sketch showing location of Cableway.

4½ minutes, but it is planned to permit it to occupy six minutes by running at half speed part of the time.

To provide against breakdown of the motor, or interruption in the power supply, there is a clutch in the driving shaft by means of which the motor can be disengaged, and a 5-h.p. Gray gasoline engine engaged both through a worm gear and through sprocket wheels. The speed at which the gasoline engine would haul in the car would be very slow, but it would be ample to meet the emergency.

If the traction cable were to break during a trip, the car would oscillate backwards and forwards along the track cables until it would come gently to rest at the lowest point of the sag of the cable, which would be about the centre of the span, as the two terminals are nearly at the same height, one being 249.5 ft. above the river level, and the other, 246.5. To bring the car back to Thompson's Point in such an emergency, a relief car and a relief traction cable are available. Attached to the driving sheave shaft, and running idle ordinarily, there is a drum on which a ½-inch wire rope is coiled, with one end fastened permanently to the drum. After the breaking of the traction cable, the free end of the relief cable would be fastened to the relief car, a light basket which holds one man and which hangs from pulleys that can be readily thrown over two of the track cables. The driving sheave would then be reversed slowly, paying out the relief cable until the man reaches the car. After the relief cable is fastened to the car by chains provided for

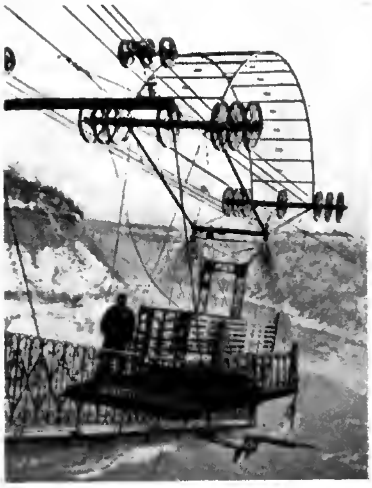

Fig. 2—Aero car and cableway.

Fig. 3—Automatic control stop.

the purpose, the driving sheave would haul the car back to Thompson's Point.

One thousand cubic yards of earth and 2,500 cu. yds. of rock were excavated for the two stations. The station at Thompson's Point is cut out of the solid rock and lined with concrete and buff tapestry brick. Two flights of concrete steps provide entrance to and exit from the landing platform. The footings for the track sheave towers and for the traction sheave tower are concrete. The towers are steel.

At the opening of the station a horizontal steel platform, 9 ft. 10 in. long by the full width of the opening, is hinged. At the outer edge of this short platform there is hinged another platform, 38 ft. long, extending over the edge of the cliff. The latter platform is suspended from the track cables by wire ropes and pulleys at the outer corners and at the hinged corners, each rope being fastened to three pulleys, one on each of three track cables. All four ropes are of the same length, so that the long platform always hangs parallel to the track cables, whatever inclination the latter may take; the four ropes are of such length that the platform clears the bottom of the car by 6 in.; therefore, the car always comes right onto the platform. The platforms are guarded at the sides by railings.

At Colt's Point a similar landing extends from the foot of the anchorage, and two flights of concrete steps lead up to the ground level.

Automatic Control

An automatic control stop is provided at each terminus which stops the car without jar within 3 ft. 4 in. The stop can be seen extending from the face of the concrete block in Fig. 3. The traction cable runs longitudinally through the 5-in. pneumatic cylinder and through the centre of the piston. A clamp on the traction cable, just ahead of the car, strikes the face of the piston, and also engages with it in such manner that the car cannot slip back from the landing platform. There are gates at both ends of the car, operated by the conductor by means of a crank, and these gates cannot open until the clamp has engaged with the stop piston, releasing a ratchet under the car. Even then, only the right gates can be opened; that is, the gates at the end of the car where the clamp has engaged. When the car starts, the clamp is disengaged by another crank, but this cannot be done until the gates are shut. This is contrived by interlocking discs, enclosed in a locked box on the car.

After the traction and track towers and sheaves had been erected, a very long rope was carried around the face of the cliff from Thompson's Point to Colt's Point. This rope was then hoisted over the tops of the trees until it could be pulled taut from Point to Point. A ½-inch wire rope was pulled across with the aid of a hoisting engine, and then the ⅞-in. traction cable was pulled into place.

Cables

The strength of the track cables is 92,000 lbs. each, allowing for bending over sheaves, and the working tension is 20,000 lbs., so the factor of safety is 4.6.

The maximum torque of the motor is 2.5 times the torque required to haul the car when fully loaded.

The maximum pull on the traction cable idler at Colt's Point is 28,000 lbs. The pull on each of the six carrying cables is 20,000 lbs., For any position of the car, the tension in the lower traction cable between the car and the transmission sheave equals half the counterweight, or 10,000 lbs., neglecting friction of counterweight and sheaves. The tension in the remaining part of the traction cable depends on the position of the car, varying from 6,000 lbs. when the car is at Thompson's Point to 14,000 lbs. when the car is at Colt's Point. The traction cable has a strength of 70,000 lbs., so this allows a factor of safety of more than 4, after deducting from strength of cable for bending over sheaves.

The sag of the track cables unloaded is 47.6 ft. The maximum sag when loaded with car and passengers is 100.1 ft. The car will still be 148 ft. above the surface of the water at the point of maximum sag.

The cost of the Niagara project was nearly $60,000 for labor and materials alone, being exclusive of the cost of engineering and other expenses, and exclusive also of the loading platforms and car, both of which were built in Spain.

The general contractors were Norman McLeod, Ltd., Toronto, on a cost plus percentage basis. The superintendent in charge of the construction was Lewis S. Roy. J. E. Taylor was resident engineer, representing Wright & Howard, consulting engineers, Toronto, who were employed by the Spanish company to adapt their design to local conditions, and who prepared the plans and supervised the construction.

Building operations in connection with the Jeffrey Hale Hospital, Quebec, will probably be commenced some time in May. The amount involved is $70,000. It is intended to extend the already existing wards, to remove the old power house and erect a new one. Another building project in Quebec is the erection of a structure for the Young Women's Christian Association on Ann Street. Tenders have been invited, and it is expected that the work of construction will be begun shortly.

Municipal "Clean-Up" Campaigns

Various Methods and Plans as Employed by U. S. Cities — Organization — Programmes — Benefits Derived (Con.)

THE greatest factor in the "clean-up campaigns" is the children, for nothing that has been done could have been accomplished without their help. Of the hundreds of cities interested in the clean-up campaigns very few can be found where the school children have not been actively identified with the work. And the co-operation of the school children is most important. No stone has been left unturned to encourage the teachers to give the children the clean-up spirit. One of the best means of reaching adults is through their children, and the education of the children themselves along these lines will contribute materially to their sense of proper community conditions when they become men and women. It is acknowledged that what is most needed in a boy nowadays is the right spirit, to insure him of a clean life in talk, habits and associates; keeping the city's streets clean is a certain responsibility that makes him more careful in his own habits. The State of Ohio spends $3,000,000 a year to produce such a boy.

Children have been pressed into service in many ways—through clubs composed of boys and girls, boy scouts, camp fire girls, city clubs, junior league clubs, junior civic clubs, etc.

There are various ways of rewarding the children for their work. Some cities believe that money prizes appeal to the children more than medals, badges, etc., and so have created special funds for that purpose, usually collected by some civic organization. Other cities give medals, buttons, puzzles, school equipment—stereopticon with lantern slides, maps, pictures, plans; sporting equipment—baseball and football masks, balls and bats; cameras, free tickets to moving pictures theatres, etc.

In some instances the school children have become enthusiastic to the point of organizing magazines in the schools, devoted entirely to the "clean-up" campaign.

Boy Scouts

Everywhere the boy scout has found his level in the "clean-up" campaigns. It is a scout law that he must be clean, and he is an expert in sanitation. Almost every troop of scouts has done its full quota in civic, local or county clean-ups. In patrol (8 boys) or by troops (24 or more), they care for school grounds, public grounds, make systematic campaigns against flies and mosquitoes, destroy their breeding places; plant trees, bushes and shrubs; in general, keep the streets free of litter and waste of all kinds. Divided into squads, they do much for city betterment. Vacant lots, waste property, fields and streets are rid of tin cans, bottles, scrap iron, weeds, and in their places flowers, vegetables and shrubbery planted; unsightly billboards removed.

In many cities the Scouts have done particularly splendid work in inspection duty, reporting all unsanitary conditions. In patrols, troops or companies (40) they are assigned to investigate and report to the superintendent of streets or the organization having charge of the "clean-up". The inspection is done day by day as the clean-up progresses, and any oversight or unsanitary condition reported at once.

City Clubs

Another method of interesting children is the organization of boys and girls into what is known as City Clubs, whose duty it is to keep the streets clean. The clubs are limited to 25 members each. The members wear buttons and each one is provided with blanks on which to report. In some instances these clubs work throughout the year, but usually their work is confined to the spring clean-up, in which event they attend to the general clearing up of vacant lots, back yards, school property, and cart it to the curbs for the city dump wagons to haul away. Chicago is one of the cities using these clubs.

In Boston, the Junior Municipal League, under the auspices of the Women's Municipal League, loaded with posters reading, "Do you have pride in your city? Then clean it up," and armed with brooms, shovels and rakes, proceeded to clean up.

Clean-up Plays:

A school in one city presented a one-act play typifying the following characters: Fly, waste paper, fire, soot, dirt, microbe, sickness, death, sorrow, poverty, cleanliness, swatter, refuse pail, fire protection, paint, scrub brush, soap, water and flowers. Lines were fitted to each character, and in the end cleanliness and happiness overcame sickness and dirt.

Although not always taking an active part in the cleaning up, women's clubs have been a great factor for good in instigating general clean-up. There is scarcely a city in the country where the women in one way or another have not done much propaganda work, and in many instances offered active service and financial support. Taking pictures of unsanitary conditions is a favorite method of bringing such conditions to the notice of citizens and health officials. Lectures on home and community gardens was one of the features of Cincinnati's campaign. One of these lectures was furnished by the National Cash Register Company.

To meet the demand for lecturers in Cincinnati, the Speakers' Committee secured the services of a number of speakers, who addressed the welfare associations, mothers' clubs, business associations, district organizations, etc.

Some cities use wire incinerators for burning paper rubbish in parks. The cage with a top prevents the paper blowing away, and a match applied reduces it to ashes in a moment.

Under the auspices of the City Improvement Committee of the Akron, Ohio, Chamber of Commerce, a successful yard campaign was carried on. Three prizes of $20, $10 and $5, and four prizes of $2.50 each were given.

Wichita Falls, Texas, offered a prize of $100 for the best kept back yard.

A prize of $25 was offered for the best "Clean-Up and Paint-Up" song in Cincinnati.

Prizes to children range from $2.50 to $5 in gold, with diplomas for honest effort, buttons with suitable inscriptions, badges, etc.

Through tireless energy the Director of Social Centers of the Public Schools in Cincinnati succeeded in having hundreds of school gardens planted. Many of these were planted in vacant lots which had formerly been the abiding place of heaps of rubbish. One was upon what had been for years an objectionable public dump adjacent to the Windsor School. Several loads of dirt were applied to this in the fall and the cost defrayed from the campaign fund.

In September an exhibit of school garden product was held and prizes offered. $25 was appropriated from the campaign fund for this purpose.

Prizes of school equipment to the children making the best showing in the growing of vegetables during the summer were given in Kewanee, Ills.

Fire Prevention and Inspection

Taking into consideration the fact that in 1914 the loss in Philadelphia alone from combustible materials was $300,000, the question of fire prevention is a big factor in the clean-up work, and at least one city, Cincinnati, has laid special emphasis upon safety as well as sightliness and cleanliness—as a result of the clean-up campaign. The efforts of Cincinnati in this direction will bear repeating:

"The success attained in the Cincinnati campaign in 1914 so impressed the State Fire Marshal that he assigned one of his assistants to spend his entire time in the 1915 season going about the state organizing in the different cities clean-up campaigns based upon the Cincinnati plan, and in which inspections by the State Fire Marshal's department played an important part. Since it is estimated that 80 to 90 per cent. of all fires are caused by accumulation of rubbish or trash of some sort, a thorough renovation of all premises in the city must decrease the risk of fire. Therefore the more thorough the Clean-Up Campaign the more work done toward fire prevention. The $600,000 reduction in fire loss, from $1,341,348 in 1913 to $793,796 in 1914, may be traced largely to the result of the Clean-Up movement. This means a reduction of insurance rates in the business district of from 5 to 8 per cent. and an annual saving of perhaps $160,000 in fire insurance premiums."

Inspection

Another distinctive feature of the Cincinnati campaign was that of inspection of the city, which became an important factor. In order to assist in the working out of the system to be used, the State Fire Marshal, with the Chief Inspector, made a special trip to Cincinnati for a conference, and later the General Secretary went to Columbus to examine the system of inspection at the office of the State Fire Marshal. The report card printed below was finally adopted. The inspection was laid out as follows:

1. Inspection in the downtown business district to be made by deputy state fire marshals and members of the State Fire Prevention Association.
2. The rest of the city to be inspected by firemen and policemen.
3. All inspection cards, when turned in by inspectors, to be sent to the office of the Cincinnati Fire Prevention Bureau, where the particular department to which each defect should be referred for correction might be indicated upon the card.
4. The cards then to be sent to the office of the general secretary for (1) tabulation to be made of all defects reported, (2) the department interested in the defect to be notified, (3) copy of the notice to the department to be mailed under two-cent postage to the person responsible for the defect.
5. After re-inspection by the various departments, and correction of the defects, the notices to be returned to the office of the general secretary with a statement in each case as to just what had been done.
6. The general secretary then to tabulate the acts of the various departments, thus making possible to set forth statistics in regard to things accomplished, something that was impossible in 1914.

The improved conditions found in the downtown section in 1915 are reflected in the fact that in both campaigns the Ohio State Fire Prevention Association followed up its work by a bulletin to the fire insurance companies upon which all defects were listed in detail. In 1914 it covered 38 pages, and only 7 pages in 1915, the district inspected being practically the same for both years. This indicates most clearly the improved conditions of 1915, and the effectiveness of the 1914 campaign toward permanently better conditions. When the time for inspection arrived 37 non-resident members of the Ohio State Fire Prevention Association came to Cincinnati and remained for several days. Their services, together with the help of the local members, were invaluable. In 1914 the inspections made by the members of the Association were handled by them alone, but in 1915 all their inspection cards took the regular course. Of the total inspections made in the city (43,424), 61 per cent. were reported free from defects. The Cincinnati Fire Prevention Bureau made inspections in the congested district during the campaign which other inspectors were unable to cover.

(To be continued)

Drainage for Wetness and Drought

The Ontario Agricultural College, Guelph, is sending out notices calling attention to the importance of proper drainage of farms and to the assistance rendered by College, when requested. The following information is taken from one of their circulars:

The great factor in moisture control is drainage, natural or artificial. Few farms are sufficiently drained by natural means. Nearly all require some artificial drainage. The problem then is, "Where shall we place our drains?" "How deep shall we put them?" "What size of tile shall we use?" The position of the drains depends largely on the slope of the field; the depth, on the kind of soil; the size of tile, on the extent drained and the fall or grade given the drain. If any farmers are uncertain about these points or anticipate any difficulties the Ontario Agricultural College will send a drainage surveyor who will, if necessary, prepare a map of the farm showing the location of the drains, the size of tile to use and the grades and depths of the drains. The cost for these services will be the travelling expenses of the surveyor, and as several surveys are made on one trip the charge is seldom over three dollars for each survey. Those who have had their farms surveyed and have installed part or all of their drains may have a new plan prepared free of charge if they will return the old plan after marking in all changes made in the original system. On the same terms as those for surveys, the College will send a man to give any farmer a start on the installation of his drains if he has had no previous experience. He will show how to set grade stakes, grade the ditch bottom, make the junctions of main and lateral, lay the tile and assist in any way required.

If you contemplate draining during 1916 or are planning for 1917 and need assistance write to the Department of Physics, O. A. College, Guelph, or your District Agricultural Office, state your difficulties and request assistance.

Clay Qualities—Testing and Sampling

To Overcome Difficulties in Manufacture and Ascertain the Possibilities of a Profitable Business

By H. B. Henderson*

THE purpose of a laboratory test is to determine the qualities of the clay, the troubles which will have to be overcome in the manufacture of any type of ware, the process best adapted to the material, and the possibilities of a profitable business.

With this end in view, we will give some observations from the experience of a number of years and based on the examination of a wide range of materials coming from practically every state in the Union and a number of foreign countries. During this time we have observed many peculiarities in materials used in the clay-working industries. Such observations as I shall present may not be new to all of you; some, probably, will not be new to any one. But why should we concern ourselves about the new things when it is the same old set of troubles that the clayworker is up against whether his factory is located in the United States, Canada, Argentine or Africa. Therefore, our first observation is: The best way to keep out of trouble is to avoid it. Adopt the principle of preparedness by first finding out the limits of your material, then stay within the boundary.

Physical Defects in Clay

This paper is limited to a discussion of clay testing, but equally important is the clay sampling. We test the clay that is sent to us, but it may or may not fairly represent the working bed of material. The physical properties of the clay affect the working behavior, and the particular difficulty is lamination, the bete noir of many clayworkers. This is a machine trouble but oftentimes it does not show its effect until the drying and then it is attributed to the drying. Frequently it will not develop its harmful effects until the burning, and then the fault is ascribed to the burning. Lamination, in brief, is simply the slippage of the clay on itself, forming planes or "slickensides" in the clay mass. If the clay is a sticky one and of an adhesive character rather than a cohesive, it will stick to the dies, retarding the flow of the clay next to the dies, while the clay within the mass flows ahead. This is die lamination and very common in the manufacture of thin-walled ware, such as fireproofing, drain tile and sewer pipe.

In an auger machine the auger cuts the clay into a spiral, which is packed into and forced through the die. If the clay is lacking in cohesiveness and in binders the layers may not bond together and under the strains of shrinkage in drying and burning they may separate. This is auger lamination, and its seriousness depends upon the degree to which the layers bond together in the burning. Badly laminated ware, such as drain tile in the green state, is simply a series of layers which may be easily peeled off. In the drying, or burning, especially if conducted too rapidly, the outer layer will shrink and crack and curl off, which we call "slabbing."

If the outer layer does not crack and peel off in the burning, it often happens that during freezing weather, after the ware is piled on the yard, the layers are forced off, one by one, and the ware goes to pieces. Ware of larger mass, such as brick, has both die and auger lamination and may be a series of more or less concentric layers from the surface to the center.

The only test for these troubles is a machine test, although often tests are made by simply working up a mass of clay by hand, drying and burning it. Such a test gives some information but misses the difficulties which might arise in machine work. The practical test is to make up ware on a machine, and in the course of this operation determine whether the clay has sufficient strength to stand factory handling, both in the green state and when dry. It is not important to determine the degree of strength; in fact, we have no standard of comparison.

Plasticity

A number of methods have been proposed and devised to determine the degree of plasticity, and while of scientific interest and value, yet they do not meet the requirements of a practical test. They may show the degree of plasticity, each method having a range of its own, but the most plastic or the strongest clay because of lamination difficulty may be the least valuable for clay-working.

The machine operation alone determines one thing the clay-worker wishes to know, namely: That the clay will make good machine ware, and that the ware will be strong enough to stand factory handling. Objections are frequently raised against laboratory tests, but these tests are most important in determining the limits of the material. In this connection, the operator's experience and knowledge of the working qualities and peculiarities of a wide range of different materials becomes most valuable. Only by relating the material under examination with other materials of a similar laboratory behavior and which have later been proven in factory practice, can he form a correct judgment as to the value of the material.

Kaolin or kaolinite is the clay base and is highly refractory. Our pure fire clays are really kaolin, although we do not use this term, but instead call them flint clay, No. 1 and No. 2 plastic fire clay. The melting point of pure kaolin is cone 5 and is lowered with increasing content of other minerals. The most common and predominating mineral associated with the clay base is silica, which is also highly refractory. It sinters about cone 26, but retains its shape above cone 30, perhaps as high as cone 34. Here, then, are two highly refractory minerals, but any mixture of the two is less refractory than either alone. In general, any mixture of refractory minerals will fuse at a lower temperature than the minerals alone.

Silica Clays

Silica plays an important part in clay ware manufacture. We use it to overcome lamination, to reduce plasticity, and to counteract shrinkage. Some highly silicious clays swell in the burning instead of shrinking and the increase in size is due to the mineralogical changes in the silica under heat treatment. These changes in volume within our kiln temperatures may amount to nearly 15 per cent. The condition of the sand, fine or coarse, has material effect on the be-

* Before National Brick Manufacturers' Association, Cleveland.

havior in drying and burning and upon the resulting product. To go into a discussion of the effects in detail would too greatly expand this paper, and it need only be said that in testing the material, consideration must be given to the generally considered inert material sand. Particularly is this true in salt glazed ware, because the glaze is dependent upon the quantity and degree of fineness of the silica.

Feldspar is another common mineral in clay and a more active one than silica, but there are few troubles traceable to it, at least in the more common wares. It is an alkali alumina silicate and is valuable in giving a permanent bond to our burned ware. It fuses from cone 4 to cone 9, depending upon its purity—probably at lower temperatures with other minerals, bringing it within an average kiln temperature for common wares. We count it as a fluxing material and it has the advantage that it acts slowly, thus giving us a safe burning range. It is not necessary to determine the feldspar in making a practical test, except for pottery wares. We are chiefly concerned with the burning behavior and need only look out for those minerals which give trouble in the burning.

Mica is also common in clays, and some clays are largely mica, as, for instance, the micaceous sands of New Jersey, formerly known as "kaolin." Some micaceous kaolins cannot be distinguished by casual examination from kaolin, yet may be 80 to 90 per cent. mica. Its determination is very important in tests for pottery bodies, but of little importance in common clays. It fuses at temperatures above that of ordinary kilns and frequently passes through the fire without any appreciable change. Mica is also an alkali alumina silicate and illustrates the point that chemical analyses, upon which many rely, are of little value. A micaceous clay and a feldspathic clay might have the same ultimate composition and yet behave widely different in the burning.

Popping

Lime minerals are very common and very troublesome. The effect of limestone pebbles is well known. The stone burns to caustic lime at about 1,600 F. and when exposed to atmospheric agencies, hydrates, swells and pops off flakes of the surface of the ware called "popping."

Clays which "pop" after burning in up or down draft kilns, often will not "pop" when burned in a continuous kiln, especially if the kiln has no advanced heating flue. The sulphur gases of the continuous kiln convert the lime into sulphate which does not hydrate. Lime in an extremely fine condition or as a constituent of a mineral which dissociates at kiln temperatures is extremely troublesome in the burning. It does not act as a flux at a low temperature nor until disassociation takes place and then it seems to act suddenly and completely. A clay bed must not always be condemned because of the presence of lime pebbles, some limestone, likely because they are earthy or perhaps dolomitic, do not cause "popping." The shale beds near Buffalo and Toronto, Ont., have intersatisfied streaks of limestone six to twelve inches thick, yet the ware made from this shale does not "pop." The ware may be soft up to a point when the lime begins to act as a flux, then hardens and begins to fuse all within a range of one or two cones. We consider three cones the minimum kiln range in practical work without excessive fuel consumption, but many limey clays will harden and fuse within two cones, even within one cone range and are impractical in commercial kilns.

(To be continued)

Quarrying and Cutting a Granite Block Weighing 225 Tons

What is believed to be the largest piece of granite ever quarried in this country for any particular purpose is the bowl, or basin, of a large fountain on the estate of J. D. Rockefeller at Tarrytown, N. Y., which was cut from a granite block measuring 22 ft. square by 5 ft. 3 ins. thick, weighing approximately 450,000 lbs., taken from the J. J. Goss Corporation's quarries in Maine. The Rockefeller fountain stands 32 ft. high, is 20 ft. 8 ins. across the bowl, and is an exact reproduction of the beautiful La Fontana Del 'Oceano in Florence, Italy. The method of cutting the block is graphically described by Mr. Goss in the American Stone Trade.

"We enjoyed a peculiar advantage in the execution of this contract since the distance from our quarry to tide water in Penobscot bay is but 1,000 feet and down grade all the way. We had a ledge of granite in our quarry 10 feet thick and large enough otherwise to get out the rough block, which was done by putting in a lateral row of plugs and "feathers" clear around the two exposed sides of the sheet at a distance of about five to six feet down from the top ledge. In addition, we drilled three horizontal holes one and one-quarter inches in diameter and six feet deep into both the exposed sides of the ledge directly in line with the plug holes. Blasting powder was exploded in the six deep holes (three on a side) and the rough block was successfully split loose from the main ledge, but with a very uneven bottom.

"By driving iron wedges in the crack split by blasting, the block was raised high enough to take the

lips of various jacks, after which it was moved from its natural bed by iron rollers to a roadway built up for the purpose, when some 70 or more knotty, spruce, wooden rollers about eight feet long and from 10 to 12 inches in diameter were employed to roll the stone about 600 feet to a position on level ground for working. A portable engine securely anchored supplied the propelling power.

"Once in position, the upper or concave side of the bowl was first hewed out, leaving the rim partly finished. Our next step was to turn up the bottom side to which there was yet attached about 100 tons of grout or waste granite that would have to come off. This was done by digging a hole wide enough to take the block in the process of turning 15 feet across the top and 13 feet deep, the end of the stone projecting about four feet over the edge of the excavation. Into this we piled loose dunnage, level full, to cushion the nearly finished rim of the basin which was heavily padded with felt. This rim of the basin had to take the impact of the enormous strain in turning the bottom side up and the basin at the stage must have weighed fully 125 tons, so you will understand that we had to be exceedingly careful.

"When all was ready, the side farthest from the excavation was bridled with the tackle of a 60-ton derrick and, by starting the mass with jacks, the straining cables of the derrick by degrees caused the block to slide ponderously into the hole, pressing down the dunnage about eight feet, and come to rest on the edge of the excavation at an angle of about 45 degrees. From this position it was slowly jacked and pulled to a perpendicular, rising over 20 feet in the air. A pier of railroad ties intended to trip the bowl on its over and downward course had been already built up in the hole to a level with the ground. Loose dunnage mixed with tree saplings to break the shock of the fall were then piled up almost as high as the bowl itself, which was then given a tilt by the cables of the derrick and with a crash came to rest bottom side up for further work.

"All the exposed surface of the bowl had to be honed or rubbed smooth which was accomplished by making a wheel-shaped wooden frame and attaching to it a series of carborundum bricks, one to follow the other and cut to fit the contour of the surface. A six-inch hole had been drilled through the exact center of the basin to admit the water pipes and into this hole was thrust an iron pin, around which the frame revolved like a great wheel driven by the power from a portable engine. After a section of surface or raceway equal to the width of the carborundum bricks was rubbed smooth, a series of new bricks were inserted in the frame overlapping the smooth race-way already made and so on until the work was completed.

"In order to finish the upper or concave side which was now down, it was necessary to turn the bowl back to its first position. This was done by filling the excavation made for the first turn, after which the bowl was rolled back to its original working position. The hole in the ground was again dug out and the second turning of the bowl was accomplished by following the method employed at first when the inner or concave side was completed and rubbed smooth down to the water line by means of the revolving frame which our workmen facetiously dubbed the 'Merry-go-round.'

"When finished, the bowl measured 20 feet and eight inches in diameter, three feet three and three-eighths inches from the top of the rim to the bottom joint with a thickness of one foot and three inches in its center, where the water pipes come through."

A Contractor's Suggestionto Engineers and Building Inspectors

By J. H. Gordon*

DUE consideration of the title of this paper and an adequate study guided by the experience of the average contractor leads us to the conclusion that "suggestions from the contractor to the engineer and inspector" must reach him through the highway commissioner and his immediate deputies in order to be effective. For the policy of the commissioner becomes immediately upon his accession the policy of the rank and file; his opinions, his point of view, his very idiosyncrasies are at once reflected in his subordinates. If he be perchance a believer in brick construction for state highways, the department immediately uncovers a host of advocates, exponents, and experts, for this form of construction; but should he be succeeded by a commissioner who is in favor of bituminous macadam, the erstwhile brick advocates subside and are replaced or join the ranks of the advocate of the bituminous roads. This reflection of policy is carried out even in detail, and if we find one administration with a hobby for nice looking culverts it will leave behind culverts with a finish that would do justice to a household mantel; but should this commissioner retire and his successor be particular about shoulders and slopes we will find the culvert work resuming its proper importance in construction and now we have a modeled and molded shoulder and a mathematically correct slope. This attitude upon the part of the subordinates is very natural and very normal There are, of course, some intrepid spirits, generally among the older and more experienced men, who always bear in mind the fundamental and are respectfully but not unduly impressed by the various hobbies that they are confronted with. We are therefore led, as stated in the beginning, to the inevitable conclusion that if the contractors are to make their position plain and their experience of value and effect they must address themselves to the highway commissioners and their deputies.

Form of Contract

The form of contract in use in most of the states and municipalities is a relic of the dark ages and contains certain stock sentences and paragraphs that are absolutely unfair to the contractor and are never included in contracts between individuals. These clauses seek to make the contractor liable not only for his own mistakes and misfortunes, and the ordinary hazards of construction, but, in unmistakable terms, fasten upon him the liability for the errors, inefficiency, or carelessness of the state's agents and employees.

We find in many of these contracts the clause: "The Contractor further agrees that he will make no claim against the State by reason of estimates, tests,

* Before American Good Roads Conference, Pittsburg.

or representations of any officer or agent of the State." We find further in this same form, that the "contractor assumes all responsibility for damages through the negligence of himself or his agents or employees"—all proper enough, but we find added, "or for any other cause." I might cite further, but from these two quotations it is apparent that there is a one-sidedness to this form which is revolting to every man's sense of justice and fair play. The phrases are old offenders, but it is time they were finally removed. The whole form of contract needs revision; it should be made modern; it should be drawn with due regard to the rights of both parties, and the great states and municipalities should assume for their agents that responsibility which they demand of the contractor for his employees. The inexperienced and timid in office too often take refuge behind these clauses, and the contractor's only recourse is the courts where he has been met before now with the charge of the judge, that having signed a contract carrying these clauses he is liable, however unjust the clauses themselves may be.

Inspection

The inequality in inspection is as marked as it is deplorable and much of it could be eliminated if care were taken to accurately state what is meant and intended.

This care should begin with the preliminary survey which is too often made hurriedly or under adverse weather conditions, and when the actual construction begins the contractor finds that his work is radically different from his idea as derived from the plans and specifications. Final surveys of excavation and embankment at times show as great a discrepancy at 25 per cent., although no great departure has been made from the plans—a result scarcely excusable. The preliminary survey should be made with the utmost care and the plans and specifications drawn therefrom should be the subject of the most careful thought and study, and when finally adopted should not be lightly changed. The location of the material to be used should be definitely and exactly stated and the responsibility for these locations and quality of material should rest with the state. Should these sources of supply be exhausted or deteriorate in quality it should be the state's burden to bear the loss and not, as now in many contracts, the contractor's. No impartial tribunal could rule otherwise.

Quality of Materials

A word here as to the quality of materials: The rise and progress of the testing bureaus has been rapid. Has too much weight been given to their reports? And is it not true that actual results in construction have been disregarded because of conflict, even slight, with theoretical test reports? Has not this insistence on exact compliance with a fractional standard added greatly to the cost of construction without adequate return?

The commissioners of highways would receive much and valuable information by more frequent consultations with intelligent and experienced contractors. No specifications should be drawn without the opinions of contractors being given due consideration, for it is the contractor and not the engineer who builds the road. Look over the records of your departments. You will find that a contractor, Mr. A, has been building good roads for many years, that his roads endure, that the repairs on them are the minimum. You will find that Mr. B, who has been building roads for a like period, has usually poor roads, requiring early and constant repairs, and yet both men were working under the same specifications and under the same engineering force. There is emple evidence to support the claim that the contractor is the one to whom we must look for results and that his judgment and experienced opinion should be given more weight than they have, in most instances, in the past.

The solution of the questions of the disposition and handling of the engineering force, and a proper equal and fair supervision of the work of the contractors is difficult and trying. The complex human equation always confronts us. In the vast volume of work in highway construction it is necessary many times to place young and inexperienced engineers in charge. Their opinion should not be given the weight of the opinion of the experienced engineer as it so often is when in conflict with the contractor. For his own protection the division engineer is apt to place the inexperienced man in charge of the work of the reliable contractor, and the more experienced and diplomatic engineer with the inexperienced and perhaps troublesome contractor, with the result that the good contractor's work is more costly to him, and as a consequence we see today many of the best men being driven from the business.

Organization

The position of commissioner of highways in a great state spending vast sums of money is arduous and trying and I know of few positions more difficult to adequately fill. The highway laws are often loosely and hastily drawn and the commissioner is hedged in with so many restrictions that he is at times almost an automaton. There are few points that I have brought out here that are not in accord with the judgment of the experienced commissioner, but until the laws are changed and he is given more discriminating power he is helpless. Politics have been the bane of road building both from the standpoint of the contractor and the engineer, and yet if the leaders of both great parties will review the past and consider the future they must conclude that as a political asset highway patronage is a boomerang.

In my opinion the ideal highway department would have three commissioners, one engineer, one contractor, and one man of affairs, with terms of office of two, four and six years. This would give a continuity to the policy of the department without making it too inelastic. It would secure the position of the engineering force, it would enable the commissioners to become acquainted with their work and their department, with the engineers under them and the contractors doing business with them. It would give time for the tests of materials and forms of construction. It would develop experts. Politics should be removed. Only under a continuous and stable policy can good and permanent work be done.

In a few short years an organization could be perfected that would be of incalculable benefit to the cause of good roads, and would be a source of pride to the citizens of the commonwealth, for the raw material is there. Taken all in all, as a body the men engaged in the engineering profession are as fine, devoted and conscientious a body of men as adorn any profession or walk of life. And may I say for the contractors that most of them value their reputation highly and are anxious to do good work at a reasonable profit, and only ask from the states and municipalities that fair, equal and proper treatment which they would demand and be granted if contracting with an individual?

Co-operation in the Brick Industry

The need of unity among manufacturers to restore the demand for brick as a building material

By W. B. Wreford*

The brick industry today is probably at the lowest ebb it has known for several years. The demand is light, and many manufacturers, to keep their plants in operation, have cut their prices so much that the price of brick is from $2 to $5 per M. lower than in 1911. The question naturally arises, "What is the matter with the brick industry?" Mr. W. B. Wreford, of Detroit, in a paper before the National Brick Manufacturers' Association in a recent convention at Cleveland, points out the lack of unity in the brick industry, and the necessity of working together in order to restore the demand for brick as building material.

What's the matter with the brick industry? The daddy of all building material is in excellent health, but if you took an able seaman, fireman, engineer or any other human being with a trade and told him that he must set back absolutely and not complain, whether you gave him anything to do or not, he would fret himself into an illness. The same thing can be done with an industry, for industry is life itself. There is an old saying, "you cannot make money without spending it." There never was a truer axiom written. Trade conditions have proven it over and over again.

I do not think any one man in the country could tell "what's the matter with the brick business." Each of us can tell what has happened to it in the particular locality in which we are working, each of us can point to instances of success here or there, caused by certain circumstances, peculiar to that locality. We go, however, into the realm of theory when we say that the principles applied anywhere will produce the same results.

While a man may talk pleasantly upon theories, he talks convincingly only upon such subjects as he has touched with his hand or seen with his eye. Therefore, I am going to endeavor to deliver a message which I hope will be more convincing than pleasant, and confine myself to organization work.

I once rode on the front seat of a stage-coach with a typical old driver, who amused me for some time killing bees by the snap of his whip. I watched him kill over a dozen in as many tries; finally, I spotted a bee-hive with at least twenty-five bees around it and asked him if he could kill them; his reply was: "Nothing doing, lad, them's organized." The story very clearly illustrates the position of the brick manufacturers. This is not a new condition nor a new statement, but stands out so clearly as a fact that it bears repetition.

I would like to see every building brick manufacturer, big or little, materially assist toward the making of a national campaign for brick. Ask any paving brick manufacturer if he would like to see the National Paving Brick Manufacturers' Association die.

About six months ago, following out a resolution passed at the last convention of the National Brick Manufacturers' Association, a group of brick manufacturers met at Indianapolis, organized and incorporated the National Building Brick Bureau, and elected officers.

* Before the National Brick Manufacturers Association, Cleveland.

Notification was sent out to all brick manufacturers, memberships and subscriptions solicited. Up to date something less than $5,000 has been subscribed.

The main idea underlying the formation of the Building Brick Bureau is to make of it a power station and clearing house for the development of local advertising and publicity all through the country.

The bureau has a three-fold task mapped out for itself in this connection and others can be added from time to time. The three primary lines of activity are to encourage advertising on the part of the brick manufacturers, to assist in preparing advertising matter and directing the lines of exploitation work, and to collect and furnish specific data for its members that will be of value in the promotion of brick as a building material against all competitors.

The bureau is organized along proper lines and has no intention of going into a wild campaign of money spending, but proposes, by systematic effort, to place before the building public facts, figures and selling talks to aid the sale of brick. One of the first services of the bureau is the publication of a booklet, entitled "Distinctive Brick Homes." If money enough can be raised, the booklet will be placed in the hands of every architect, builder and contractor in the United States. If you will secure a copy of the booklet, you will see in a moment the advantage such a campaign would have. It takes money to do this, which means that every brick manufacturer should contribute something, a $50 or $100 check would help, though it is not enough to gain the actual results desired.

You all know how thoroughly the cement industry is organized. Annually they expend in their publicity campaign twelve millions of dollars, which, as they say, represents but a fraction of a cent of each dollar's worth of business done. The market value of material has gone steadily upward, yet the market value of cement, as shown in the following table, never reached the market value of brick in any one of the given years:

	Amount Manufactured.	Market Value.
—Year 1912—		
Brick	11,194,795,000	$ 91,303,448
Cement	85,925,651 bbls.	69,554,385
Lumber	39,158,414,000 ft.	601,081,645
—Year 1913—		
Brick	10,892,434,000	$ 93,849,649
Cement	89,541,348 bbls.	89,550,527
Lumber	38,387,009,000 ft.	589,142,588
—Year 1914—		
Brick	9,704,874,000	$ 83,187,045
Cement	87,257,552 bbls.	80,553,203
Lumber	37,887,142,000 ft.	*580,557,629

*Estimated.

Still they have an organized publicity fund of twelve millions of dollars, which does not represent the money spent by the individual firms for advertising purposes. Then take the lumber industry which spends annually $50,000 through its National Lumber Manufacturers Association, and is after more money and unquestionably they will get it. They have the jump on the brick manufacturers, and while $50,000 is not such a big jump when all the brick manufacturers in the United States are considered, it's a lead that must be overcome. The ever present reason that brick men must organize is the fact that brick is sold in communities, especially common brick, whereas the cement and lumber interests have the entire country for their market. This fact alone makes it especially vital that the brick interests should organize for publicity and advertising purposes. Just stop to think what a wonderful assistance a semi-monthly magazine published by the National Building Brick Bureau would be to you, containing suggestions for advertising and publicity copy. It would not be expensive and if a start were made by all brick manufacturers agreeing on an assessment, for organization purposes, of one-half cent per thousand on all brick manufactured it would stimulate the brick market to a degree almost unbelievable. However, there can be no half way station. No small group of brick manufacturers can make a success of such an undertaking. One and all must realize its importance. It is simply a case of "United we stand, divided we fall."

You will say that what I have already stated can be done in one community necessarily cannot be done in others. However, there are thousands of things that can be worked out for the brick manufacturer, no matter in what section of the country he might be in. No effort need be made to tell you how to run your business, but suggestions could be offered that would materially assist the individual manufacturer.

Here, for instance, is a sample of what one of the big cement concerns are doing. The letter which I am about to read has been received by every live architect in the United States.

New York, N.Y., January 3, 1916.

My Dear Sir:

Beginning January, 1916, an unusual and, we believe, a significant series of our advertisements will appear in the journals of the architectural profession. They will deal with the merits of reinforced concrete for industrial buildings. And also for the first time they will extend to architects the services of our Reinforced Concrete Engineering Department.

The function of this department is to furnish such data as architects may require for their consideration of reinforced concrete, and to lend such aid as may be desired for preparing designs in which the reinforcement is completely detailed. This service is free.

Simultaneously there will appear a series of advertisements to prospective owners in the standard magazines, directing their attention to the merits of reinforced concrete for industrial buildings. They will not recommend reinforced concrete indiscriminately for buildings not suited to its use. They will emphasize the advantages for certain kinds of industrial buildings. They will tell owners that it is permanent, fireproof, economical, sanitary and that it carries the lowest insurance rates.

The result of this we hope to make the owner see the wisdom of permanent construction, so that he may be the better prepared to receive his architect's recommendations.

The object of this entire campaign is obviously to increase the legitimate use of cement. We naturally want you to use Atlas, but the whole purpose of this letter will be missed, and our project itself not understood, if you are left with the impression that in order to obtain the services of our Engineering Department you must use Atlas. We can well afford to be satisfied with our share of the increased business that should result.

Yours very truly,
The Atlas Portland Cement Co.,
John R. Morron, Pres.

Just think at what a little cost could be maintained a brick bureau for the disseminating of ideas to architects concerning brick.

With your indulgence I am going to tell you what has been done through a local organization in Detroit, known as The Detroit Brick Manufacturers and Dealers Association, operating since a year ago last September. Partly as the result of the work of this association it is necessary for every brick plant in Detroit to work full force all winter in order to prepare for the present demand and the rush of the spring building season. There is nothing very difficult about the work of the association. Here are a few of the lines of endeavor that are being followed:

During the first year they paid for 1,000 inches of newspaper advertising and as the result of this they had 2,000 inches free publicity published. Let me call your attention to the fact that names of brick manufacturers are not used in any of the copy.

They also have a building sign, a card 22x28 inches, which is placed on every brick building under construction. These signs cost $2.80 per hundred. Then there is the road sign. These signs are placed on all roads leading into Detroit with the arrow pointing toward Detroit. These signs are 14x22 inches and cost $2.00 per hundred.

The wagon sign is used on all wagons that haul brick. They cost $5.00 per hundred.

The back of the Detroit building code carries the Build with Brick advertisement. The cost is $3.00 per year, 5,000 copies being printed by the publishers.

Our test booklet, known as "Practical Tests," contains facts pertaining to brick and hollow tile construction. These tests were conducted under the supervision of Professor F. N. Menefee, in charge of the Materials Testing Laboratory at the University of Michigan. These tests cost about $3,200, a copy of the booklet has been supplied to all architects, contractors and builders in the city of Detroit.

Space has been retained at the Builders and Traders Exchange permanent exhibit at a monthly cost of $35. An architect is now at work drawing plans for a miniature brick house to build of miniature common brick. The size of this space is 10 feet by 11 feet.

Last, but not least, the booklet supplied by the National Brick Bureau. This booklet contains information relative to the history of the brick making industry, in addition to the twelve designs for brick homes. These designs were selected from among the ones that were submitted to the Indianapolis Star during its recent competition for the best drawings for brick homes to cost not over $7,500. All Detroit architects and contractors have been supplied with a copy.

This gives a general outline of our activities in Detroit, which you see is simple publicity and advertising work that can be successfully handled in any community.

Summing up, what answer do we get to "What's the Matter with the Brick Business?" As I see it the answer is, "Be Alive." Make them talk brick and they will buy and use it.

The last word I have to say is on the everlasting question of price. My suggestion along this line is to create a demand and the price will take care of itself.

The Design of Modern Power House Foundations and Footings

By J. N. Hatch*

IN the early uses of electricity before long-distance transmission of energy had developed, the amount of power required from any one station was small. Therefore the requirements in the way of buildings for housing the generating machinery were simple. Today, however, with the centralization of power in large units, the problem of working out a proper design for the building and foundations has become an important branch of engineering.

The layout of the machinery is the fundamental determination in planning a power station, but if this is made arbitrarily without any special reference to the building design, it often becomes difficult, if not impossible, to design a neat well-balanced building to inclose the machinery. For any power-station design it is desirable that the mechanical, electrical and building engineers work closely together so that the machinery and the electrical layout can be arranged with some reference to the building features. To accomplish this it is generally necessary to make a number of preliminary studies and then by a process of elimination and rectification work out a design that will best serve the end of all. As soon as a design that will determine the main features of the building is tentatively decided upon, the work of the real design of the building can be started.

Site

One of the first things to be decided is the kind of foundations that will be required. The site for a power station may be on the lake shore, where the high waves and shifting sands make a problem of one nature; or on salt water, where the corrosive conditions are severe; or on the bank of a river, where the rise and fall of the stream between extreme high and low water is 60 or 70 ft.; or it may be along a river where the quicksands are extremely treacherous, or along a river where the foundations will be on solid rock. If the site of the proposed building is in a city or town, it is often possible to gain considerable knowledge from the investigation of structures that have been built in the vicinity and from an inquiry of the nature and character of the underlying soil. But it often happens that a power station is built far away from any other building and the engineer in charge must make all preliminary determinations from his own investigations.

Generally it is necessary to have a number of borings made, and in addition it is often advisable to have a few test holes dug down as deep as the earth can be conveniently excavated. These test holes will afford a means of examining the nature of the different strata of earth. From this examination a good idea can be obtained of what loads the earth will safely bear per square foot. Whether the foundation is simply to rest upon the earth or must have piles or caissons is a matter to be decided by the building engineer from his investigation of the soil and surroundings.

It is generally necessary to bring a large intake and discharge tunnel into the center of the building. This complicates the foundation problem. If the underlying material is solid rock, the tunnel can be driven through it, but if it is sand and gravel to an indefinite depth, the problem is much more difficult, particularly if the tunnel must be sunk to a depth of 50 or 60 ft. so that it will always be below the low-water level of the river on which the station is located.

Foundation Materials

Next to solid rock, sand and gravel are about the best materials upon which to place a foundation for a heavy building, but they must be confined and must not be undermined by deeper foundations near-by. Clay is always a treacherous substance on which to place a heavy foundation, especially if it is subject to alternate saturation and extreme dryness. It is difficult to judge of the load that clay will safely bear, as it seems that almost any clay is subject to some compression, which, although taking place slowly, may continue for many years and become a significant amount in time.

If, upon an examination of the site, the engineer thinks that the underlying materials will not carry the building safely, he must resort to some method of increasing its bearing power sufficiently to make it safe. If there is a hard underlying stratum at a reasonable depth, it may be determined to drive piles, but if the underlying materials do not become solid until a depth of 80 or 100 ft. is reached, so that piles cannot be utilized, it may be desirable to use so-called caissons. These are made by digging wells 5 to 8 ft. in diameter to a solid footing, and then filling with concrete and distributing all loads to them.

If a heavy building is to be placed on soil of a quicksand nature where piles would not be practicable, a method considerably used is to place the entire structure on a reinforced-concrete mat, generally 5 or 6 ft. thick and thoroughly reinforced in both directions, both top and bottom, in the hope that if there is settlement it will be so uniform over the entire building as not to be noticeable. One serious difficulty with the arrangement is to know what is going to happen where the tunnel joins the mat. If the entire mat settles considerably, it is likely to break away from the tunnel where the two join.

It is clear that the determination of the style of foundation best adapted for any particular location is a problem of itself and must be solved for that particular site and the particular building which is required.

Design of Foundations

As soon as the general arrangement of the machinery has been decided upon and a skeleton plan and cross-section of the building has been worked out and the elevation of the exterior has been tentatively fixed upon, the detailed location of all walls, piers and columns must be decided, so that the foundation walls and footings can be designed. A fairly close estimate can be made of thicknesses of walls, sizes of piers and outside dimensions of columns just from a study of the skeleton of the building, and a fairly close approximation can be made of what the weight of the machinery will be from the weights of similar machinery used elsewhere. It is therefore possible to figure the load from the roof downward that will be transferred to the walls and columns and piers. A careful schedule

* Before Western Society of Engineers.

should be made of these loads, showing at what elevation they come and what each is from. These should be put on an outline plan of the building and on a cross-section, so that they can be readily checked over and so that if, after more data are received, there are changes required, it will be easily seen how the original assumption will be affected. This loading schedule will be referred to until the building is completed, and should be carefully made and checked. With the schedule completed, the design of the foundation can be undertaken.

Foundation walls and footings for buildings and machinery are made at present almost without exception of concrete. If below the high-water level the basement floor must be carefully built and joined to the walls so that there will be no leakage.

In the modern large station the smoke-stack is frequently carried on a steel structure over the boilers. This has a number of advantages—it permits a saving in land and in the size of the building and allows one uninterrupted row of boilers. The argument against this arrangement is its extra cost. In some the stack structure is joined rigidly to the building structure and in others it is not connected in any direct way to the building.

Power-Plant Chimney Foundations

Stacks and chimneys that rest directly on the earth do not involve any special features that need to be dwelt upon. It is necessary to remember that under the maximum wind conditions the earth pressure at the toe of the foundation on the leeward side of the chimney may become as much as twice the average earth pressure over the entire base with no wind blowing. Care must be taken to insure there being no uplift under the toe of the foundation on the windward side.

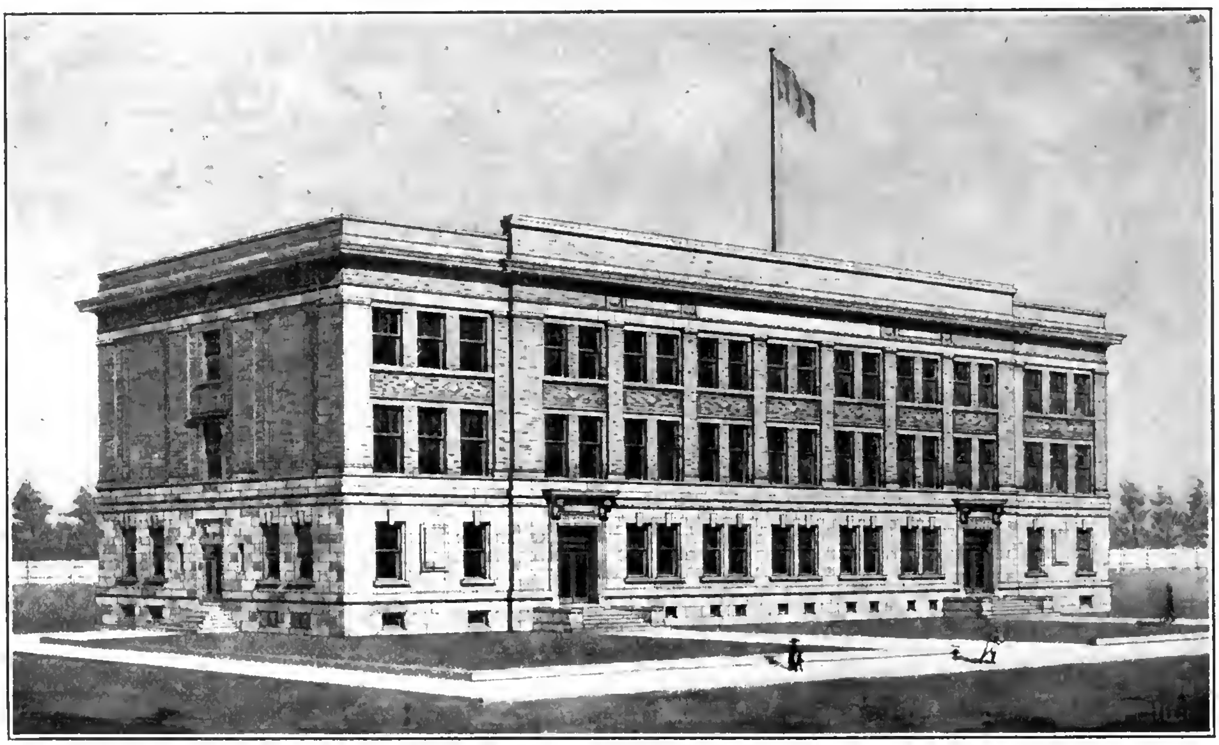
While the purely architectural features should be given careful study and the whole design of the station should be made with the architectural scheme in view, still the usefulness of economy of the plant should not be appreciably hampered to carry through some preconceived scheme. In fact, this is not necessary, for a building of good appearance can be worked out in harmony with almost any well-planned machinery layout, especially if the two are worked out together.

Work Started on Papineau Roman Catholic School at Montreal, P.Q.

On instructions of the Roman Catholic School Commissioners, Montreal, Messrs. Marchand and Keroack and Messrs. Doucet and Morrissette have drawn up plans for a new boys' school, to be constructed on a site on Papineau Avenue and Lafontaine and Lalonde Streets, Montreal. The general contract has been let to Laurier & Rondeau, Montreal.

The total site is 365 feet long and 157 deep, this including a large playground at the Lalonde Street end. The dimensions of the building are 65 feet by 164 feet, the area being about 22,000 square feet. The structure is to be set back 30 feet from the main frontage on Papineau Avenue, there being the same amount of free land at the rear, forming another play ground.

The building will consist of a basement and three stories. The foundations are to be of concrete, with



Architect's perspective of Papineau School, Montreal, P. Q.

a granite base, and grey canyon sand stone to the first floor. From here the exterior will be of Kittanning brick, sandstone trimmings and terra cotta cornices.

There are to be six entrances, the two main ones on Papineau Avenue, one each on Lalonde and Lafontaine Streets, and two at the rear of the school. The stairways will be constructed of slate for the steps and landings with cast iron risers.

The basement will contain a storage room, coal bin and equipment for heating and ventilation, including a boiler for the hot water system.

The plans show a large recreation in the centre of the ground floor with toilet adjoining; on one side are to be the caretaker's quarters and store room, and on other administration offices. The floors on the recreation room and in the toilet will be of ceramic tile, while in the caretaker's quarters and the offices they will be of concrete slab covered with hardwood. Throughout the building there are to be suspended ceilings on metal lath. Terra cotta will be used for all interior wall linings.

The next two floors will give accommodation for instruction. Each floor will contain seven class rooms, with a cloak room adjoining each class room. There will also be toilets, and on the first floor a teachers' room is to be provided. On the second floor a stenographers' room takes the place of the teachers' room. The class rooms are to be divided by a main corridor ten feet wide running the entire length of the building. The rooms are finished in chestnut, while the floors of the corridor and of the rooms are to be of maple. Ceramic tile will be used for the floors of the various toilets. The class rooms will be reached from the main entrance by two wide staircases.

The roof is to be of tar and gravel. A fire escape with iron stairways, will be provided on the Lalonde Street side of the school. The building, it will be noticed, is to be exceptionally well lighted as the site, being open on four sides, gives facilities for the provision of a large number of windows.

How to Build Good Roads at Lowest Cost for Modern Traffic

By F. E. Everett*

IN these days of modern road building, when large sums of money are being expended for highway improvement, when any sort of so-called permanent type of pavement will cost from $10,000 to $30,000 per mile, many engineers and commissioners are brought face to face with the question of how the mileage necessary to complete their highway system can be built without bankrupting the state or county which they represent.

There is no doubt that the high class types of road are most essential and necessary on trunk lines or main roads between cities or county seats, that are subjected to all sorts of traffic from horse-drawn vehicles to motor trucks. But, outside of these main arteries, is it not necessary that a cheaper type of road be constructed? Even if a commonwealth can arrange a bond issue ample to construct its whole system of bituminous macadam, concrete or brick pavement, is it not economy for it to construct a less expensive road? I say emphatically, yes.

With our present completed system the tourist can reach the mountains by any one of three routes and return by either of the other two, but had we been obliged to confine ourselves to a high class type of construction, we could have made but a poor showing on any one of these routes, to say nothing of building three. In the building of these three lines we have resorted to the material we had at hand. In a good many localities there are deposits of good gravel and where this occurs it has been comparatively easy to get good results. In numerous other places gravel could not be found or if found it was of an inferior quality lacking in some important feature, perhaps in binding material, perhaps as is more often the case, in metal.

Under these conditions we resort to a combination of material to get the desired effect. If the gravel is sandy, with no binding material we alternate the layers of gravel with clay or marl or sometimes mix the two materials thoroughly by harrowing or some such other method. If there is not enough metal we have found that with a stone foundation, material of a very inferior quality can be used for surfacing and with very satisfactory results.

We have in New Hampshire a mixture of clay and sand and gravel called hardpan. This is probably more common than any other native material. This material mixed with sand or sandy gravel or even laid directly on the stone foundation or telford is quite satisfactory under our system of maintenance.

Construction

In construction we pay due attention to the essentials—alignment, grading, drainage and foundation. In connection with the alignment it may not be out of place to say just a word as to our methods of survey. Contrary to the general practice adopted by most states, we do not make a plan of the road first and then plot the new road on paper.

The first procedure is to establish the center line of the new road on the ground, correcting the old alignment where possible. With this as a base line we are enabled to stake out the new layout and also make a survey of the existing conditions. Stakes are set every 50 ft. on an offset from the center line. When the cross sections are taken an elevation is obtained of the top of these offset stakes so that when the finished grade is obtained it is easy to determine the cut or fill from the top of these stakes.

If for any reason it is desired to change the alignment after the survey is plotted on the plan, the stakes are on the ground and it is an easy matter to figure the offset either way from them. I believe this method of survey and staking out saves the expense of one engineering operation in the field.

The essentials of drainage and foundation, we give particular attention to, for with these gravel or dirt roads it is very necessary that the water be thoroughly taken care of. A great many of our roads have the telford foundation, especially if the gravel is of an in-

*State Highway Commissioner of New Hampshire, before American Good Roads Conference, Pittsburgh.

ferior quality with a tendency to be heavy or sticky in wet weather.

We have built most of our roads 21 ft. wide from ditch to ditch. No doubt many of you will say that this is not wide enough. In some cases I am inclined to think so myself. However, they have answered very well for the traffic they are subjected to. Our original specifications called for 15 ft. of metal and 3-ft. dirt shoulders. The gravel was laid in three courses of sufficient thickness to make the whole compacted mass 8 ins.

Today we believe that we can get better results by sub-grading the entire width of 21 ft. in practically a flat section. If, however, the stone foundation is used we crown it slightly. On this section the surfacing material is placed in two courses, using a dumping board or dumping the loads in such a way that all the material will be handled over.

We desire to roll each layer, using in most cases a horse-drawn corrugated roller. Some of the larger towns, however, use a steam roller and some of the smaller ones have no roller and depend on the traffic to do the compacting, keeping it in shape by dragging and raking. Of course we get results quicker where we are able to use a sprinkler and thoroughly wet down the separate layers, but in most cases we have to depend upon nature for the wetting. The finished section has a thickness of metal of about 10 ins. in the center and practically nothing on the edges. This gives a crown to the road of about 1 in. per ft., which we believe is necessary for roads of this nature.

We have built in the ten years that the department has been in existence, 1,171 miles of road of which 558 is trunk line, outside of the compact portion of towns having a population of over 2,500. Of this latter amount 422 miles are of gravel construction and represent an expenditure of $1,614,503, or an average per mile of $3,826.

Maintenance

After any road has been properly rolled and the surface has been made compact and smooth, it is desirable that it should always be maintained in that condition. It is a common rule that the finest roads are the result of good construction and system of maintenance whereby every defect is corrected before it has time to cause serious damage. This rule is chiefly applicable to a gravel road for the very obvious reason that if we are to build gravel roads and expect them to give their users the same satisfaction that the more expensive types would give, we must maintain as near a true section as is possible, free from ruts and holes.

The question next arises what kind of maintenance will accomplish this result. As we all know there are two general forms of maintenance, which may be called continuous maintenance and periodical repairs.

It is not my purpose to analyze the merits or defects of these systems. Both have their advocates and critics and both their strong and logical argument. Personally, I feel that both systems are correct. The type of road to which they are applied should regulate their selection. It would certainly be a waste of money to employ constant maintenance upon a high class pavement which we have every reason to expect will wear uniformly until such time as to need resurfacing. On the other hand it would be poor policy to let a gravel road go until it needed resurfacing.

It is important that every rut and hole be filled as soon as they appear for they will hold water which will soften the gravel bed and cause the road to wear rapidly.

The question now arises: What is the best method to adopt to accomplish this continuous maintenance? There could be only one answer to this so far as the gravel road is concerned, namely the patrol system. A patrolman equipped with a one-horse hitch, shovel, rake and drag, etc., given a mile of road per diem, will find plenty to do. A gravel road to insure the maintenance of its cross section should be dragged after every rain. Under the periodic system we could not do this as it was impossible to have the maintenance gang at the proper places at the proper times.

Dragging

As we all know, a gravel road can be too wet or too dry to drag. In other words there is a certain time after a rain when the road is in the best possible condition to work and obtain results. The patrolman constantly on the road is going to know just when this time arrives. He is going to discover the weak places. He will see the small hole when it starts and before it has developed into a large one or a series of small ones. He can patch the roads in the early stages of disintegration without serious trouble or excessive cost.

Theoretically, if a patrolman gives his gravel road proper attention it should never need resurfacing. He will cart on and distribute enough new gravel to take the place of that which has been worn out under traffic. The patrolman fully illustrates that old adage, "A stitch in time saves nine."

As an illustration of the favor in which we hold the patrolman's services, I will cite the increase that has been made in this branch of our organization. In the year 1911 there were two men employed as patrolmen on one of our trunk lines for about two months. This was our first attempt with the patrol system. We have already appointed, for the year 1916, 225 patrolmen. These men will be employed from April 1, or sooner if the weather conditions permit, until December 1. Their average pay will be $3.25 per day. Now arises the question: How much money can be justifiably expended in the maintenance of a gravel road?

Assuming the cost of a modern country road pavement of the so-called permanent type at $15,000 a mile (conservative) and supposing this to be paid for by 20-year bonds at 4½ per cent., the annual charges for interest on and redemption of the bonds amount to about $1,150 per annum. It is safe to assume that even the most permanent type of country road pavement will require repairs and maintenance of at least $50 per mile per year, or in round figures we have a minimum of $1,200 per mile per year as the cost of the improved road.

Assuming that a good gravel road may be built for $4,000 per mile (which we have shown is more than the average cost of New Hampshire roads), the annual charges for interest on and redemption of bonds (if the roads are built by bond issues) at the end of 20 years would amount to about $310. Therefore, it is theoretically economical to spend nearly $900 per mile per year for the maintenance of gravel roads, if for that sum the roads can be maintained in a condition equal to a pavement in the $15,000-a-mile class.

Our claim is, that in New Hampshire, we are able to maintain this condition on four-fifths of our roads. This four-fifths carries an average traffic of about 300 to 600 vehicles, mostly motors, per day during the vacation season.

From the comparison just cited, we find that we can economically spend $900 per mile per year for maintenance. Under the patrol system we do not find this expenditure necessary. Taking forty towns in New Hampshire whose state roads have been built of gravel and maintained by the patrol system, we find that in the year 1915 our average cost of maintenance per mile was $240. This cost includes in some cases the surface application of a light asphalt or non-asphaltic oil. I will leave it to your judgment if this type of road is not the most economical for moderate traffic.

A doubt will probably exist in the minds of some when they take into consideration the amount of traffic that these roads carry and compare it with some of the elaborately worked out theories as to the wearing qualities of plain gravel roads, but we have the experience of several years of this type of maintenance and construction as a refutation.

In fact any of these gravel or so-called combination roads, which were originally built of necessity, have worn so satisfactorily that today we are advocating this sort of construction as a principle. We believe that for four-fifth of our trunk line roads this type of construction is absolutely satisfactory for moderate traffic, if properly maintained, and by far the most economical road to build.

Completed Reinforced Concrete Girder Causeway at Corpus Christi, Texas

Nueces County, Texas, have completed, at a cost of $166,500, a causeway, 8,700 ft. long connecting the city of Corpus Christi with San Patricio County across the Corpus Christi Bay. The following details of the work are taken from Engineering Record. The causeway forms an important link in the system of roads connecting San Antonio with a number of resorts on the Texas Gulf coast.

The construction adopted consists of 6,200 ft. of protected fill, and 2,532 ft. of short reinforced concrete spans, providing sufficient waterway for the passage of high waters and floods of the Nueces River. It also includes a small bascule bridge with a 32-ft. clearance.

The bridge portion, consisting of 76 reinforced concrete girder spans, with 30-ft. clear openings, and the draw span were placed at the south end where the deepest water existed, and provides a total waterway at high tide of 8,600 square feet. The piers consist of a bent, creosoted long-leaf pine piling, 24 lbs. treatment, with a concrete cap 2½ ft. wide, extending down to the existing bottom. The top of the piers is an elevation of 3 ft. above low-water datum. The concrete was placed in the water with a tremie. Piers are reinforced with four rods, two on each side on the row of pile heads, to avoid danger of cracking opposite the piles.

The piles vary in length up to a maximum of 55 ft. They were driven to a penetration of ½ in. under a 6,800 lb. gravity-drop, steam hammer, striking sixty blows per minute.

Reinforced-Concrete Girders

The spans are composed of four reinforced-concrete girders 32 ½ ft. center to center and 30-ft. clear span. The bottoms of the outer girders are in elliptical arch form, and the inside girders are corbelled. The girders and the concrete floor slab were run continuously through five spans; at every fifth pier the entire superstructure was completely cut by a contraction joint.

The roadway is 19 ft. 10 ins. wide between concrete railings of ornamental type, top of floor slab being 9 ft. above low-water datum. Provision for continuity in both floor slab and girders is made by bending up reinforcement.

The roadway is drained by cast-iron gratings and scuppers through the curb. A wiring conduit and anchor bolts were provided for future installation of light brackets over alternate piers.

Concrete and Form Work

The concrete was composed of washed crystalline limestone gravel 1:2:4 mix, and was reinforced by deformed square rods of medium grade structural steel.

Corpus Christi Causeway—76 - 30 ft. concrete spans with 32 ft. Bascule Bridge.

A field testing laboratory was maintained throughout the work. Tests of 4-in. cubes of concrete for girders and floor showed an average strength of 2,800 lb. per square inch at 30 days.

Placing Paneled Knockdown Forms

The forms for the spans were carried without falsework upon eight lines of 10 x 20-in. timbers 32 ft. long resting on the piers in pairs on either side of the four girders. The forms were composed of dressed lumber screwed together in panels and oiled. The panels were supported on the aforesaid timbers and held in position by a system of knockdown framing requiring no nailing, and wired only for the outer girder sides. The forms were used eight times with very little reworking.

The drawspan is of the Strauss bascule lift type. The girders have a span of 42 ft. from center of main trunnion to bearing of moving leaf, and provide a clear span between fenders of 32 ft. The floor is a 4-in. slab of reinforced concrete carried on steel floorbeams and stringers and with 2 in. of trap-rock granolithic for the wearing surface.

Oyster Shell Approach Fills

The approach fills, 200 ft. long at the south end and 6,000 ft. at the north end, are composed entirely of oyster shell dredged from the shell reef which underlies the greater portion of the entire structure. The top width is 40 ft. and the side slopes 6 to 1, making a base of approximately 120 ft. width. A berm of 100 ft. was left between the toe of the slope and the dredge pits. The fill was dredged in to elevation 6.00 above low water and subsequently crowned to elevation 6.50 for the roadway.

The fill is protected by very shallow water on the west side; by a bar and by comparatively shoal water on the outer or eastern side fronting on Corpus Christi Bay. The anticipated shoaling action due to stoppage of cross currents as above mentioned has already developed to a noticeable extent. Although the fill is 30 miles inland from the Gulf of Mexico and is exposed to no severe storm nor wave action, it was thought best to supplement the protection from natural conditions by the following construction precautions: First, the use of oyster shell for building the entire fill; second, the adoption of very flat side slopes comparable to the slopes of the adjacent sand beaches; and third, by the use of brush faggots and riprap to protect the toes of the fill.

Brush Faggots and Riprap

The faggots consist of bundles of mesquite brush somewhat over 8 ft. long and 12 in. in diameter bound securely and tightly by four wire stays. These faggots were placed at right angles to the center line with brushy ends out and in continuous rows, simultaneously with the placing of the fill. Two rows of faggots were placed on the outer side and one on the inner side, except near the abutments, where three and two rows respectively were used. The fill, and especially the finer particles of shell, settled into the crevices of the faggots to form a solid toe. On top of the other slope as thus constructed was placed the riprap composed of 50 per cent. one man and 50 per cent. two man stone placed by hand in an apron one layer thick and 14 ft. wide. The heavier rocks were placed at the foot of the slope. Eighteen thousand faggots and 2,600 tons of riprap were used.

The abutments and bulkhead wings protecting the ends of the fills at the junction with the bridge are of concrete extending down to the existing bottom and resting on creosoted bearing piles and a line of 6 x 12 in. creosoted sheet piles forming a continuous bulkhead.

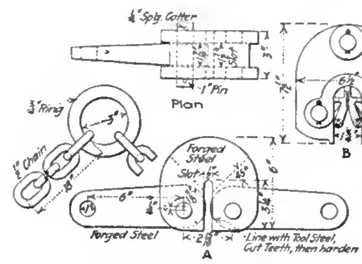
Road Surface and Approach

The road surfacing over the concrete slab is composed of a mat course of tarviated trap rock, and the surface of the shell fill after it becomes thoroughly compacted by traffic will be treated likewise. All materials for the construction of the bridge had to be imported from distances in excess of 125 miles. The Causeway was constructed by W. L. Pearson & Co., Houston, Texas.

Clamps for Pulling Steel Piles

In pulling steel sheet piling the use of a hook in a hole in the pile is not always effective, as the hook may tear through the metal without loosening the pile. Two forms of clamps designed to give a sure grip on the pile are shown herewith.

In the design shown at A the web of the pile is gripped between the eccentric cams formed by the ends of two levers journaled in a heavy steel forging. A chain sling is attached to the outer ends of the levers;



and as the pulling strain is applied to the sling, the serrated faces of the cams grip the web between them In the second design B the arrangement is more compact. The two jaws, or grips, are carried by arms pivoted in the horseshoe frame, so that the downward pull on the jaws (due to the resistance of the pile) tends to draw the arms inward, thus forcing the jaws together.

Slate is generally quarried on the gallery system, that is to say, terraces are cut out of the hillside at regular intervals one above the other, each terrace forming a vantage ground from which the adjacent rock-face may be worked. The terraces are connected by inclined planes, up and down which the slates and quarry debris are hauled in small trucks by means of winding gear. Where a large amount of worthless rock overlies the slate, the latter is often more economically obtained by running galleries into the valuable bed, the workings being thus underground.

Road surfacing, as distinguished from applications of oil for dust laying, is covered in principle and practice in a booklet, Trinidad Liquid Asphalt, just issued by The Barber Asphalt Paving Company (Philadelphia). The essentials of successful "carpet coating" with asphaltic materials are fully explained. As illustrations the pamphlet contains photos of park drives, city boulevards, suburban streets and country roads resurfaced with liquid asphalt by both hot and cold applications. Full specifications, in the form of explicit directions for the laying of carpet coats, are included.

Personal

Mr. R. H. Lee has been appointed city engineer of Kamloops, B. C.

Mr. John Pender West, a Winnipeg architect, has enlisted as a private in the 44th Canadian Battalion. He has been recommended for a commission.

The city council of Fredericton, N. B., have offered the position of city engineer to Mr. George McKnight, an ex-alderman. Mr. McKnight is engaged at present as an engineer with the St. John and Quebec Railway Company, having been engaged in the construction work on the St. John Valley Railway from the commencement of that project.

Obituary

Mr. Henry Hartung, a well-known sewer contractor, of Hamilton, Ont., died on April 2 at the age of 51 years.

Mr. George Smith, engineer, Lindsay, Ont., died suddenly while on a visit to Toronto. He was sixty years of age.

Mr. W. D. Baillarge, chief engineer of the city of Quebec, has suffered a sad bereavement in the loss of his wife, who died on April 5. Mrs. Baillarge was a sister of the Hon. L. A. Taschereau, Minister of Public Works for Quebec.

Mr. W. E. Mann, a civil engineer, and formerly divisional engineer for the Grand Trunk Pacific Railway, Edmonton, Alta., died on March 31st as the result of a fourteen-foot fall to the bottom of an elevator shaft in the Alberta Hotel, Edmonton. He was about 45 years of age, and unmarried.

Mr. H. N. Dancy, a member of the firm of H. N. Dancy & Sons, masonry builders and contractors, Toronto, died on the 4th inst., at the age of 70. Mr. Dancy was associated with many important buildings in Toronto, among them being the new Knox College, the administration building of the Toronto General Hospital, and the Lumsden Building. He was born in England, and came to Canada at ten years old, spending practically his whole life in Toronto.

Mainly Constructional

East and West—From Coast to Coast

The indications are that Winnipeg's building in 1916 will be at least double that in 1915.

The Grand Site Construction, Limited, is the name of a new Montreal concern capitalized at $49,000.

The Robert Simpson building at Regina, Sask., is expected to be completed by the middle of April.

The Hamilton Stock Brick Supply Company, Limited, Hamilton, Ont., have been granted a charter.

The Chadwick Brass Company, Limited, Hamilton, Ont., have changed their style to the Wentworth Brass Company, Limited.

Twenty-five building permits, of the value of $26,230, were issued by the city of Quebec during the week ending April 1.

Messrs. Leonard Foulds and A. B. Bowes have opened an office at 166 Bay Street, Toronto, as structural and civil engineers.

The Brown Copper & Brass Rolling Mills, Limited, are erecting a brass rod and shape mill in New Toronto, Ont., at a cost of $125,000.

A two-storey building, finished and ready for occupation in eight days' time, has just been completed in Trail, B. C., by Mr. W. K. Esling.

The Robidoux Sand Company, Limited, has been incorporated with a capital stock of $30,000. The head office of the company is in Montreal.

The Port Hope Manufacturing Company, Port Hope, Ont., expect to start operations at once, and will probably employ about two hundred men.

Construction work on the new building at Winnipeg for the T. Eaton Company is progressing rapidly. All of the caissons are to be completed by April 15.

The Leary Brick Company, of Carman, Man., who have an order for 750,000 bricks for the dome of the Winnipeg Parliament Building, are now turning out 20,000 bricks a day.

During the month of March the city of Montreal issued 119 building permits, of a value of $243,345. In the corresponding month of 1915 171 permits, of a value of $246,695 were issued.

A plan is on foot to revive the granite-quarrying industry on Grindstone Island, in the St. Lawrence River. It is stated that New York parties have leased the property for the purpose of operating it.

F. E. Rivard, A. J. Violette, C. L. Cyr, F. J. Cyr, R. Devost, and E. P. Nadeau, all of Saint Leonard, N. B., have formed a co-partnership to carry on business in Saint Leonard under the style of the Saint Leonard Brick Company.

To overcome the difficulty in securing a proper entrance to the city of Hamilton, Ont., a bridge 1,400 feet in length is planned by the Toronto-Hamilton Highway Commission. The highway and the Hydro radial will both run over the bridge.

During the month of March the city of Vancouver issued 48 building permits, of a value of $205,485, compared with 75 permits, value $30,915, for the corresponding month of last year. For the three months of 1916 the figures are $293,749, as against $271,037 for the same period in 1915.

Figures showing the progress made on the enlarging and finishing work of the Rogers Pass Tunnel from January 27 to February 26, are as follows: East end, main tunnel, 603 ft., total 10,151 ft.; west end, main tunnel, 619 ft., total 8,868 ft. The main tunnel faces, at February 26, were 7,381 feet apart.

Extensive improvements to the water supply of MacDonald College, Montreal, have been completed, and the new plant was placed in operation on April 2. The improvements consist of an elevated steel water-tank, holding 100,000 gallons, supported on four steel columns. A mechanical gravity filter plant has also been installed.

Arrangements for the building of the rear portion of the new City Hall, Winnipeg, are now being seriously considered by the Board of Control. The work is expected to cost in the neighborhood of $200,000, which, covered by a loan at 5½ per cent., would cost the city $11,000 per annum, but would bring all the departments under one roof.

The cornerstone of the Salvation Army's new training college on Davisville Avenue, Toronto, was laid on April 1 by Commissioner W. J. Richards, in the presence of a large gathering. The College, which is being erected as a memorial to the late General Booth, will be one of the most up-to-date institutions of its kind in the country. It is estimated to cost $150,000, and the site comprises eight and a half acres. The building will be four storeys high.

The construction of a twenty-million-dollar bridge across San Francisco Bay, connecting San Francisco and Alameda, is a possibility of the near future. The proposed bridge would be four miles long, and of an average height of 30 feet above the water. The greatest altitude of the bridge would be 125 feet at one place, to permit the passing of lofty-sparred sailing vessels. The plans provide for four railway tracks and two roadways—one for automobiles, the other for slower-moving vehicles.

Quebec, Que.
The contract for roofing, heating, plumbing and electrical work required in connection with the store now being built for J. N. Rondeau, 6 Lachevrotiere Street, has been awarded to A. Noreau, Fifth Avenue, Domaine Lairet, and the painting to Garneau & Artean, 230 d'Aguillon Street.

J. A. Voyer, 63 Scott Street, has let the general contract for the erection of a store and residence on Artillerie St. to W. Boucher, 42 Bayard Street. Estimated cost, $5,000. Brick construction.

St. Catharines, Ont.
Work has been started on the erection of a factory for the Dominion Food Company, Russell Avenue. The general contract and masonry have been let to Newman Brothers, St. Paul Street, and the carpentry to C. F. Monk, Wilson Street Approximate cost, $20,000.

Stratford, Ont.
The general contract for an addition to the premises of the Williams Trow Knitting Company, St. Patrick and Erie Street, has been let to the Metal Shingle & Siding Company, Preston.

The contract for plumbing and sheet iron work required in connection with the addition to the premises of the Avon Hosiery Company, Erie Street, has been awarded to J. R. Myers & Sons, 99 Ontario Street, and the painting to A. Cash, 168 Ontario Street.

Toronto, Ont.
The contract for masonry required in the erection of a garage for W. J. Fennell, 6 DeLisle Street, has been let to the Britnell Contracting Company, Baxter Street, and the steel work to Canadian Allis-Chalmers Ltd., 212 King St. W. Approximate cost, $10,000.

The contract for masonry required in the erection of a business block at Bloor and North Streets for F. Nicholls has been awarded to William Edwards, 337 Rusholme Road, and the carpentry to Hudson & Mosley, 5 Jerome Street.

The general contract for re-building the Princess Theatre has been let to Farrington Construction Company, Detroit, Mich. Smaller trades will be sub-let. Approximate cost, $200,000. Architect, C. Howard Crane, Ford Building, Detroit.

Residences

Brigden, Ont.
John Poland is preparing plans of a residence, estimated to cost $3,000 Frame and white brick construction.

E. Johnston has commenced the erection of a residence, estimated to cost $3,000 White brick construction.

City View, Ont.
John R Daoust, Raden Avenue, is about to rebuild his residence, at an ap-

proximate cost of $3,000. Electrical work may be let. Frame construction.

Exeter, Ont.

The erection of a residence is contemplated by Ernest Davis. Estimated cost, $3,000.

Georgetown, P.E.I.

John Stewart proposes to build a residence, at an approximate cost of $4,000.

The erection of a residence is being considered by John Dalziel. Estimated cost, $3,500.

Grafton, N.B.

The erection of a residence is being considered by H. Smalley. Approximate cost, $3,000.

Halifax, N.S.

The Eastern Investment Corporation, Cragg Building, will receive tenders until May 1st for heating, plumbing and electrical work required in the erection of a residence on Larch Street.

Hamilton, Ont.

Plans have been drawn for three residences to be built by D. Hamilton, 1306 King Street E. Frame construction. Approximate cost, $3,600.

Ingersoll, Ont.

New plans are being prepared for the residence to be built on Thames Street for F. Wright, care of Wright Dry Goods Company. Red brick construction. Approximate cost, $4,000.

Tenders on the erection of a residence are being received by G. C. Wright, care of Wright Dry Goods Company. Approximate cost, $5,000.

Kingston, Ont.

Thomas Andre, 240 Earl Street, is about to commence the erection of two residences, estimated to cost $5,200. Brick construction.

London, Ont.

Hyatt Brothers, 288 Egerton Street, will shortly commence the erection of three residences on Ridout Street South, estimated to cost $10,000. Tapestry brick construction.

Plans of four bungalows to be built on Windsor Avenue are being prepared by Norman S. Roberts, care of Roberts Engraving Company, Dundas Street. Approximate cost, $11,000. Stucco construction.

Max Lerner, 502 Hill Street, is about to prepare plans for an apartment house to be built on Dundas Street, at an approximate cost of $25,000. Carbex brick construction.

J. C. Anderson, Industrial School, is preparing plans of a residence to be built on Duchess Avenue, at an approximate cost of $3,500. Red pressed brick construction.

Plans will be prepared by T. H. Janes, Market Lane, for three residences to be built on Bruce Street. Approximate cost, $10,000.

Watt & Blackwell, Bank of Toronto Building, are preparing plans of a residence to be built for H. N. Abel, 61 Craig Street. Approximate cost, $10,000. Tapestry brick construction.

D. A. Graham, 3 Perry Street, proposes to build three residences, and is preparing plans. Red pressed brick construction. Approximate cost, $10,000.

Plans are being prepared for a number of residences to be built on Hamilton Road for Mrs. Mary Graham, Marmora Street. Estimated cost, $10,000. White Brick construction.

R. H. Smith, 191 Wharncliffe Road, is preparing plans for a bungalow, estimated to cost $3,500. Tapestry brick construction.

A. Evans, 905 Queens Avenue, has prepared plans for a residence, estimated to cost $3,000, and will shortly start work. Brick construction.

H. Pocock, 552 King Street, will shortly commence the erection of two residences. Red pressed brick construction. Approximate cost, $7,000.

Lynnville, Ont.

The erection of a residence is contemplated by William Walmsley. Approximate cost, $3,000.

Middle Sackville, N.B.

Rev. A. V. Landry proposes to rebuild his residence this spring.

Montreal, Que.

F. A. Job, 163 Jacques Street, has commenced the erection of a residence. Approximate cost, $3,000.

Ottawa, Ont.

Mark Wilson, 61 Irving Avenue, is considering the erection of a residence, estimated to cost $4,000. Brick veneer construction.

Port Colborne, Ont.

Russell Adams is considering the erection of a residence on Elm Street, to replace that destroyed by fire.

Quebec, Que.

Lavoie & Frere, 52 Jeanne d'Arc St., are preparing plans of a residence to be built on Cartier Avenue, at an estimated cost of $10,000. Brick construction.

M. Cauchon, 309 Richardson Street, will shortly start work on the erection of five residences, estimated to cost $20,000. Artificial stone construction.

Roundhill, Alta.

M. M. Burkholder, Dodds, Alta., is about to start work on the erection of a residence and barn.

Seaforth, Ont.

James Watson is considering the erection of a residence and will prepare plans. Estimated cost, $3,000.

St. Elie de Caxton, Que.

Denis Brodeur is considering the erection of a residence, at an approximate cost of $3,000.

Toronto, Ont.

J. Lucan & Company, 508 Dupont St., are receiving tenders for finishing three residences on Arlington Avenue. Work includes carpentry, plastering, painting, glazing and galvanized iron work.

J. G. Hough, 346 Parliament Street, is receiving tenders on concrete foundations for five residences in the Todmorden District.

J. F. Alexander, 8 Temple Avenue, is about to commence the erection of a duplex residence at an approximate cost of $7,000, and requires tenders immediately on excavation. Brick construction.

W. P. Levack, 519 Roxton Road, has started work on the erection of a residence on Gothic Avenue, estimated to cost $3,800. Smaller trades will be let. Brick construction.

A. A. Mitchell, 502 Palmerston Avenue, has commenced the erection of a duplex residence, estimated to cost $6,500. Smaller trades will be let.

Work has been started by William Davis, 3 Scarboro Road, on the erection of a residence, estimated to cost $3,500. Smaller trades will be let.

H. Lucas, 118 Felstead Avenue, has commenced the erection of a pair of residences, estimated to cost $4,000. Smaller trades will be let. Brick construction.

McIlroy & Lowry, 105 Clendennan Avenue, have commenced the erection of two residences, estimated to cost $6,000. Smaller trades will be let.

E. Gagnon, 2359 Queen Street E., is receiving tenders on all trades required in the erection of apartments, estimated to cost $20,000. Brick construction.

J. D. Naylor, 129 Glenholme Avenue, has commenced the erection of a residence, estimated to cost $3,500, and is receiving tenders on smaller trades. Brick construction.

Work has been started by S. B. Green, 111 Evelyn Crescent, on the erection of a residence on Conduit Street. Approximate cost, $3,000. Smaller trades will be let.

Walkerville, Ont.

Harold Wilson, Windsor, will shortly start work on the erection of two residences at Windermere and Cataraqui Streets.

Plans are being prepared for a residence to be erected for Mrs. E. C. Walker, Willistead, Walkerville. Work may start this season.

Welland, Ont.

D. F. Forbes, Temple Building, is preparing plans of a residence for D. Dick, Jr. Estimated cost, $10,000. Brick construction.

CONTRACTS AWARDED

Fonthill, Ont.

The following contracts have been let for the erection of a residence for F. Wellington:—masonry, F. Hoare, St. Paul Street, St. Catharines; carpentry, C. F. Monk, Wilson Street, St. Catharines; electrical work, Clifford Electric Company, Ontario Street, St. Catharines; heating and plumbing, J. Peart, King St., St. Catharines; painting, Rachar & Hyatt, 86 Main Street, Welland; plastering, Dakers & Hemphill, 51 St. Catharine Street, St. Catharines.

Halifax, N.S.

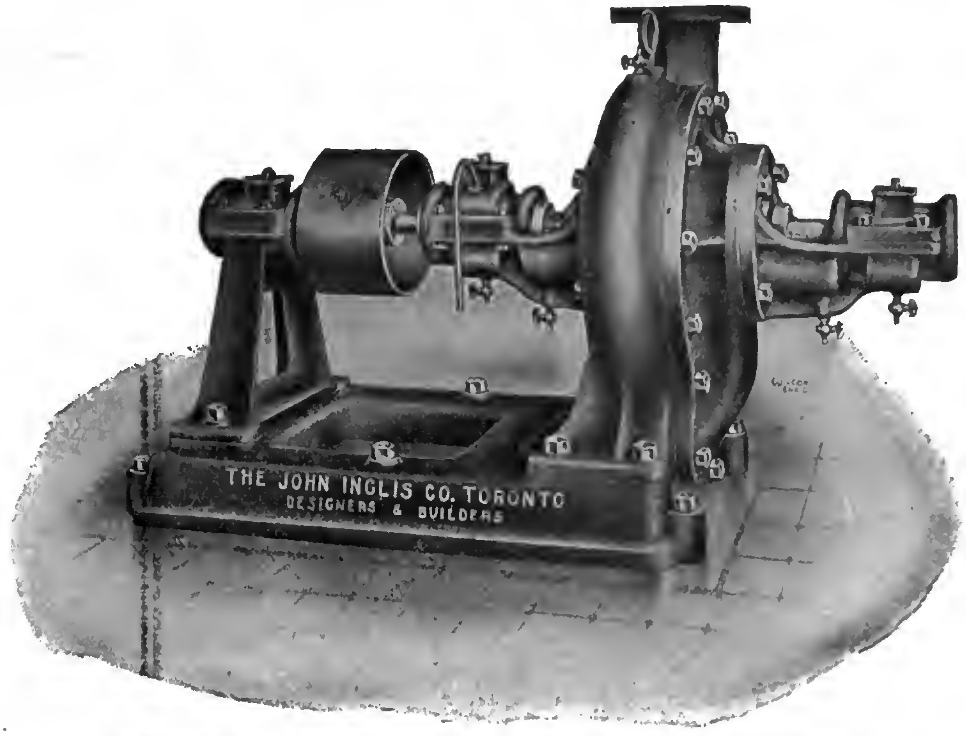
The Eastern Investment Corporation, Limited, Cragg Building, have awarded the following contracts in connection with the erection of a residence on Larch Street and flats on LeMarchant Street:—heating, Longard Brothers, 213 Hollis Street, plumbing, W. S. Craig, 316 Upper Water Street; electrical work, J. Starr, Son & Company, Granville Street.

Hamilton, Ont.

The following contracts have been awarded in connection with the residences which are being built by J. H. Somerville, 166 Prospect Street:—masonry, Lemington & White, 140 Rosslyn Avenue; plastering, Fred Mountain, 35

(Continued on page 52)

PUMPS



Horizontal Belt Driven Turbine Pump supplied the University of Toronto.

THIS Pump is hydraulically balanced against end thrust and in addition has a water cooled thrust Bearing. The Pump is arranged so that it may be operated with guide vanes or without for demonstration purposes. Oil ring bearings, Hydraulic Balance and water cooled thrust bearings are standard for all "Inglis" Turbine Pumps.

We make pumps of all kinds for any service.

INGLIS' PRODUCTS ARE "MADE IN CANADA"

Write us for prices.

ENGINEERS AND BOILERMAKERS

14 Strachan Ave., Toronto, Canada

Ottawa Representative:—J. W. ANDERSON, 7 Bank Street Chambers

Residences

West Avenue N.; heating and plumbing, H. Barnes, 93 Clyde Street; electrical work, T. Thornton, 174 Balmoral Ave.

R. S. Mason, 43 Kensington Avenue, is building five residences, estimated to cost $3,000 each, and has awarded the contract for masonry to Lemington & White, 140 Rosslyn Avenue.

The general contract, masonry and carpentry for the erection of residences for R. Sharp, Alexandra Street, Mountain Top, have been awarded to Andrew Spittal, 489 Concession Street. Brick construction. Approximate cost, $3,500.

Kingston, Ont.

The general contract for the erection of a residence for J. Connor, 575 Princess Street, has been awarded to James Gough, 170 York Street. Pressed brick construction. Approximate cost, $3,500.

Work will start shortly on the erection of an apartment house for James Elder, 207 William Street. The masonry has been let to H. W. Watts, 98 Frontenac Street, the carpentry to Henry Hunter, 332 Barrie Street, plumbing to Elliott Brothers, 77 Princess Street, electrical work to H. W. Newman Electric Company, 79 Princess Street, and painting to T. Milo, Princess Street.

Lachine, Que.

The general contract for the erection of residences for G. Guzzi, 43 Notre Dame Street, has been awarded to B. Lacolli, 70 Tenth Avenue. Brick construction. Estimated cost, $3,000.

Levis, Que.

The general contract for the erection of a residence for A. Cherrier, Bienville, has been let to J. Blais, Levis. Estimated cost, $4,000. Brick construction.

London, Ont.

The general contract for the erection of a residence for James R. Haslett, 521 Richmond Street, has been let to H. Hayman, 491 Ontario Street. Approximate cost, $3,500.

Work is about to start on the erection of a residence for D. J. Ferguson, 503 Quebec Street. Estimated cost, $4,000.

Hyatt Brothers, 288 Egerton Street, are about to start work on the erection of a residence for Charles Gilbert. Approximate cost, $4,000. Red pressed brick construction.

The general contract for the erection of a residence on Hill Street for Charles Lee has been awarded to Hyatt Brothers, 288 Egerton Street. Red pressed brick construction. Approximate cost, $3,500.

The general contract for the erection of a residence for D. C. McNaughton, care of McCormick Manufacturing Company, has been let to Harry Hayman, 491 Ontario Street. Approximate cost, $4,000.

Work is about to start on the re-building of a residence for James Black, care of Grigg House. The general contract has been let to Jones Brothers, Hamilton Road. Estimated cost, $3,000.

The general contract for the erection of a residence for George Mills, 527 Dundas Street, has been let to Harry Hayman, 491 Ontario Street. Red pressed brick construction. Approximate cost, $3,000.

C. J. Pink, 451 Hamilton Road, has awarded the general contract for the erection of a residence to Tutt & McRae, 90 Chesley Avenue. Red pressed brick construction. Estimated cost, $3,500.

Maisonneuve, Que.

The contract for carpentry in connection with the residences in course of erection for M. & O. Dufresne has been let to I. Allard, 1360 Des Erables Street, and for asphaltic mastic roofing to H. H. Symmes & Brothers, 42 St. Sacrament Street.

Montreal, Que.

The contract for electrical work required in connection with alterations to a residence for A. P. Stuart, 27 Summerhill Avenue, has been let to E. A. Gregory, 1594 Cadieux Street.

Quebec, Que.

The contract for carpentry required in the erection of a residence for James Brown, 71 Fleurie Street, has been awarded to E. Morissette Ltd., 208 Latourelle Street, the roofing to N. Barbeau, 36 Bridge Street, and the heating, plumbing and electrical work to D. Cote, St. Louis de Courville, Que.

The contract for painting in connection with the erection of a residence for Boisvert & St. Laurent, 56 d'Artigny Street, has been awarded to A. S. Bedard, 116 Des Stigmates Street, and the heating, plumbing and electrical work to A. Fournier, Abraham Hill.

Raleigh Township, Ont.

The general contract for the erection of a residence for George Davidson, R. R. No. 6, Chatham, has been let to Robert Lewis, 120 St. Joseph Street, Chatham. Estimated cost, $5,000.

Sarnia, Ont.

The general contract for the erection of a residence for W. A. Watson, Front Street, has been let to David Giffin, the masonry to E. McDonald, and the plumbing to F. Goodwin & Company, 215 Christina Street. Frame and stucco construction. Approximate cost, $4,000.

St. Catharines, Ont.

The following contracts have been let in connection with the residence in course of erection for A. F. Fifield, 157 Ontario Street:—masonry, Newman Brothers, 71 St. Paul Street; carpentry, steel work and roofing, R. B. Williams, Beecher Street; heating and plumbing, H. A. Bald Company, Academy Street; plastering, Dakers & Hemphill, 51 St. Catharine Street; painting, Leach & Jones, James Street; electrical work, Sandham & Roberts, St. Paul Street.

Toronto, Ont.

Work is about to start on alterations to the residence of F. G. B. Allan, 6 Wellesley Place. The contract has been let to F. Browning. Tenders are being received for excavation. Approximate cost, $4,500.

W. R. Maton, 173 Glenholme Avenue, has been awarded the general contract for the erection of a residence for F. Trelford, 1036 St. Clair Avenue West. Stucco and tapestry brick construction. Approximate cost, $5,000.

Walkerville, Ont.

The general contract for the erection of a residence on Kildare Road for F. E. Allum, Detroit, Mich., has been awarded to Euclide Jacques, 87 Assumption St., Windsor, and the masonry to Cross Brothers, 25 Louis Avenue, Windsor.

Westmount, Que.

Anglins, Limited, 65 Victoria Street, Montreal, have commenced the erection of a residence on Willow Avenue N. for Harding & Heward, and are receiving tenders on roofing and electrical work. Approximate cost, $14,000.

Windsor, Ont.

The general contract for the erection of flats on Dougal Avenue for Mrs. G. Hallett, Langlois Avenue, has been awarded to Lambert & Braithwaite, 10 Riviera Street, Sandwich. Approximate cost, $8,000.

Decent Consideration

Dean Cappon, of Queen's University, voices the sentiments of a very large percentage of the Canadian people when he says: "Let there be decent consideration for those who think they have good enough reasons not to go, at least as yet, to the war."

Possibly, if Dean Cappon spoke all that is in his mind, he would put it more strongly. Doubtless he has seen the ill-advised methods of recruiting that are being utilized from day to day by the rank and file of various battalions. Doubtless he realizes that the present system of semi-coercion has little to commend it, and in a very large number of cases does more harm than good. Its biggest weakness, perhaps, is that it fails to discriminate between the man who holds back because he is a coward and the man who delays because his intelligence tells him that his proper place, as yet, is where he is.

The methods of recruiting as practised in Canada, if Toronto may be taken as a criterion, lack nothing so much as intelligence and good sound horse-sense. There is ample and laudable enthusiasm—but misdirected. Khaki enthusiasts fail to see, or refuse to see, that the business of the country is next in importance to the war, and as such demands fair consideration. They fail, or refuse, to see that many a young man, however desirable as a member of their unit, may be, by comparison, still more useful as a civilian in this present time of stress. They fail, or refuse, to grant to the intelligent individual the right to use his own judgment as to when is the proper time for him to give up the one and take hold of the other. In other words, the present system of recruiting is specially designed for the dilettante, the indifferent, the man lacking in moral and mental fibre; it is a reflection on the man who does his duty as he sees it.

* * *

All of this, and more, no doubt, Dean Cappon has prominently in mind when he makes a plea for merely "decent consideration" for the men who do their own thinking. If these men had followed the line of least resistance many of them would have been in uniform months ago. Fortunate it is, as we see it, that, in the absence of the slightest apparent effort on the part of our Government to cope with this problem of filling up the ranks of the numerous battalions they have authorized, there are men strong enough to brave the jibes and insinuations of these miscellaneous, misguided recruiting agents. They are simply making juvenile attempts at a man's job! How can we combat efficiency except with efficiency?

The men who are strong enough to "think" today, men who are strong enough to resist following the lines of least resistance, cry out for some movement on the part of our Government which will enable us, as a nation, to carry on our share of this war in such a way as to conserve in the best possible manner our fighting resources—present and future. There is not a man of these who is not ready to go when and where he is told—if the authority who gives the order **knows.** Why doesn't our Government find out? Why hasn't it an inventory of every citizen of Canada, that it could say to him, "Here is your place!"? But instead of acting, our Government delegates this authority to the illiterate private in the ranks, and, indirectly at least, authorizes the man of small intelligence to badger and coerce the man who sees his duty clearly and is doing it. Why cannot our Government move in this matter? Why cannot they give so important a question at least "decent consideration"?

Mountains of Northern Labrador

The regular monthly meeting of the C. S. C. E. was held in the Chemistry and Mining Building of the University of Toronto at 8 p.m. on April 13. A very interesting descriptive address was given by Prof. A. P. Coleman, entitled "A Visit to the Mountains of Northern Labrador."

The speaker described how, to reach Torngat Mountains in Northern Labrador, 1,300 miles from Toronto as the crow flies, he had to travel a roundabout way of 4,000 miles—by rail to Sydney, N.S., ice-breaker "Bruce" to Port aux Basques, Nfld., railway (3½ ft. gauge) to St. John's, steamer to Main on Labrador coast, motor boat to Hebron (last Moravian settlement); balance of the way to Komaktorvik Bay, latitude 59 degs. 30 min. in a fishing skiff with two Eskimos.

Prof. Coleman mapped the country in the neighborhood of Komaktorvik Bay. The highest mountain was 4,700 feet—which, of course, the Professor, as usual, climbed: one of Dr. Coleman's recreations is reaching the highest point of the highest mountains. Proceeding southward, Nakvak Fjord, which the speaker described as comparable in beauty with the fjords of Norway, was also explored. In this neighborhood the highest summit reached 5,000 feet.

Various items of keen interest to his listeners were noted by Dr. Coleman as the lecture proceeded. He spoke of the fine trout in the northern rivers, the largest he had ever seen, golden and copper color, and more than two feet long. He spoke also of the great number of ice-floes encountered on the journey to and from the north land, and the influence these must have on future navigation possibilities in and around Hudson Bay. On the various mountains glaciers were very frequently met with.

Bids, Bidders and Bidding

By G. Alexander Wright

To bid or not to bid? That is the question—whether it is better to be idle and save money, or take a job and lose it?

Is it any use to figure? That is the perplexing question of today for the competent and careful bidder, for he knows that the more competent and careful he is, the less chance he has of competing and getting a job with any profit in it. It certainly looks as if our present estimating methods are a failure from the bidder's standpoint. What is to be done?

Is it that there are not jobs enough to go around? Or, are there too many bidders? And are they too aggressive, too eager for the good of the business? One thing is certain, that so-called competition among the building industry has degenerated largely into cut-throat practices, and trade destruction.

If bids to owners are so low that the contractor is unable to make a profit legitimately, what happens, and whose fault is it? Is it the owner's? Is it the architects's? We think not. It is well known that many architects do not favor such conditions. They will, when about to invite bids, prepare their list of bidders, say eight responsible and well-known contractors, sufficient competition surely, one would think (especially as the owner is not paying for the time and study these eight men will give to his plans and specifications). Then see what happens! First the subs get wind of it, then the material men; these tell their friends, their customers and other material men that such and such an office is taking figures on a job. Those in the game know what follows. By the time bids are actually received the architect is unwillingly swamped with bids, good, bad and indifferent. Probably fifteen or twenty. The usual result is that the better, or rather more competent type of contractor, is badly beaten by the "uninvited" bidders, who force their way in and crowd them out, by submitting ridiculously low bids, based, generally speaking, upon incorrect quantities, and not incorrect prices.

Such methods destroy what the better class of architects seek, viz: "legitimate" competition. Where in the name of common sense, is the logic of this? Nobody is benefitted by such methods, not even the uninvited bidders themselves. Such men, however, are largely responsible for the ruinous and demoralized condition of the building business today. These men will beg almost for the chance to figure a job, regardless of anything. There are architects who realize the conditions and will try and stand such bidders off, at the risk of making an enemy. But it is no use. They take it as a personal affront if refused. Sometimes other means have to be adopted, to save these bidders from themselves, to save them wasting their time, but this is seldom appreciated.

Some way must be found of identifying these kinds of bidders, if they belong to an organization, and of convincing them of their folly, and of the great injury they do the building business as a whole. Should this prove insufficient, then other means might be adopted. Something must be done, and soon. That is certain.

It is so easy to blame architects for the conditions, but the truth is the remedy lies among the bidders themselves. If the latter want a square deal, they can get it. If they want better conditions, it is within their power to get them. But they must act, and co-operate. Other objectionable features of present loose practices are a source of inconvenience to the architects, the majority of whom would appreciate better methods among contractors. If the architect selects a sufficient number of bidders for a job, why should bidders compel them, almost, to increase their list two and three fold? Then there are the numerous and entirely unnecessary interruptions the architect experiences answering inquiries after bids are opened. Not from the bidders originally selected, nor even from the uninvited bidders, but from the almost endless number of sub-bidders, specialty men, material men who have given figures to the bidders, and who afterwards keep the architect's office busy answering inquiries about the bids, instead of getting their information direct from the bidders for whom they figured. Even if bids are to be opened at a fixed time in the presence of bidders, it is found that even this does not obviate these objectionable features, as it certainly should.

The whole question is a complex one, it is true, but the bidders themselves can do something, and a great deal, if they will but co-operate towards improving conditions. It is up to the men in the business.

These columns are always open to a discussion of these subjects, and to suggestions in aid of betterment. We shall be glad to publish our readers' opinions concerning "Bids, Bidders and Bidding" in future issues, either with or without their names appearing.

All we want is practical facts and suggestions for betterment. Every reader has some ideas, and all are at perfect liberty to express them. Let us hear from you. Address "Editor" Contract Record, Toronto.

The Pittsburgh-Des Moines Steel Company, Pittsburgh, Pa., are distributing a new illustrated booklet on railway service tanks. There is considerable information in this booklet which will be of interest to our readers. One of the illustrations, which are numerous, shows a 100,000-gallon-capacity tank installed for the Grand Trunk Pacific Railway at Melville, Sask.

Shall I Build Now, or Wait? Comparative Prices Today and at Outbreak of War

[Continued from April 12]

ALTHOUGH, generally speaking, the two main items entering into the cost of a building, other than steel construction, are the masonry and the carpentry, there are a variety of miscellaneous items to be considered which in the aggregate are as important as either of these. Indeed, one would not be far wide of the mark if he divided the ordinary building under these three headings—mason, carpenter, miscellaneous—allowing each of them one-third of the total cost.

Under miscellaneous, fall such items as heating, plumbing, painting, glazing, trimming, hardware, plastering, wiring, and so on. How does the price of these items today compare with prices at the outbreak of war?

In two previous issues we have published information with respect to the mason and carpenter contracts. Roughly summarized, the masonry cost, one-third of the total cost, has been reduced anywhere from 10 to 20 per cent: carpenter work, another third, remains practically the same, with a slight tendency to increase. Therefore, if the cost of the items which fall under the head of "Miscellaneous" have not increased more than 10 to 20 per cent., to offset the saving in masonry costs, it is evident that building today is at least no more costly than at the outbreak of war.

Hardwall Plaster

The prices of hardwall plasters, now generally used on better-class buildings, were exceptionally low for some months after the war broke out. Within the last few months, however, one manufacturer reports that a considerable advance has taken place, until today neat hardwall plaster will perhaps average 15c to 20c per ton higher than in August 1914: this represents an increase of only 3 or 4 per cent, however. Another manufacturer states: "We have made very few changes in our prices, and where we have there has been a slight reduction. There is every indication that, instead of prices advancing because of the high cost of production, 1916 prices will be lower than last year, due to the keen competition caused by the necessity of each manufacturer securing a fair share in a shrinking market so as to keep his organization together."

Price conditions in this material vary somewhat in various localities, however. In the city of Montreal the competition was so keen for a time that a reduction from $11 to $6.50 held for several months. In the maritime provinces, on the other hand, we are advised the price of hardwall plaster has just been increased 70 cents per ton, and the trend of prices has been upward. The tariff, too, has been a contributory factor, as many of the materials used in the manufacture of hardwall plaster come from the United States.

Plumbing and Heating

There are many items which enter in these contracts and we are indebted to the James Morrison Brass Manufacturing Company, Toronto, for the following interesting information:—

"The price of seamless drawn brass tubes advanced about 100 per cent. between August 1914 and August 1915, and the price today as compared with that of 1914 is an advance of 120 per cent. Brass rod and sheet brass advanced 100 per cent. between August 1914 and August 1915, and present prices are 165 per cent. of that of August 1914.

"Regarding raw metal, such as copper, tin, etc., the average price of lake copper in January 1915 was 13.89 cents per lb.; in December 1915 it was 20.37 cents per lb. The price of pig tin January 1915 averaged 34.3 cents per lb., and in December 1915, 38.75 cents per lb. This metal reached a price during the year as high as 57 cents per lb.

"The price of pig lead in January 1915 was 3.74 cents; in December 1915, 5.34 cents. During the interval it reached as high as 7 cents per lb. Spelter (zinc) was selling at 6.52 in January 1915, and in December 1915 the price was 16.91; in the interval it had gone as high as 22.6 cents."

This company state that the prices covering copper, tin, zinc, and lead have advanced still further during the present year; tin was as high as 55 cents per lb. a few days ago; copper, 28.5 cents per lb.; zinc-spelter and lead were also proportionately higher. This gives a fair idea of the trend of the metal market.

Very interesting figures have been furnished by another firm. This information is in the form of percentage advances. The items illustrated in the table below cover pretty fully the requirements of the average plumbing or heating installation:—

	Advance 1915 P.C.	Advance 1916 P.C.
Enamelled ware	..	10
Earthenware	..	12½
Soil pipe and fittings	..	22
Lead pipe	20	55
Lead traps and bends	20	40
Galv. range boilers	30	52½
Brass pipe	25	100
Iron pipe (black)	..	45
Iron pipe (galv.)	..	60
Iron pipe fittings	10	45
Compression work	10	33 1-3
Brass valves	10	50
Iron valves	7½	30
Radiators	12	22
Heating boilers	7½	17

(To be continued)

The average strength of Douglas Fir stringers, subjected to a process of creosoting involving boiling under vacuum and resulting in the removal of 35 per cent. of the total moisture in the specimen, has been shown to be approximately five-sixths of the original strength, compared to a one-third decrease with other processes.

Messrs. Peden & McLaren, architects, have moved from 20 St. Alexis Street to 54a Beaver Hall Hill, Montreal.

The Use of Oil as a Dust Preventative

Methods of Treating Road Surfaces With Asphaltic Oils as a Cure or Prevention of Dust. Some Cost Figures

By W Huber, A. M. C. S. C. E.*

The problem of dust prevention on rural roads has become acute only since the advent of the automobile as a serious factor in transportation. Prior to that time neither the nature of the traffic nor its speed was such as to cause serious inconvenience to travellers on the roads or the inhabitants along them. It is not to be denied that the deterioration of properly constructed stone roads before this time was due in a large measure to the formation of dust, but it was not nearly so rapid as it has been since the use of automobiles has become general. It is now generally admitted that if the formation of dust can be prevented, by removing the causes of this formation, the life of the road will be increased, to say nothing of the added comfort and convenience to the users of the road.

Dust

Dust may be defined as the detritus resulting from the abrasion or pulverization of the material composing the road surface. It may result from a number of causes, including the grinding and pulverizing action due to the impact of horses' feet and vehicle tires, the shearing action of self-propelled vehicle wheels, the physical actions of rain, frost and wind, the chemical action set up in the weathering of stone, and, usually most important of all, internal attrition or the grinding together of the individual stones of which the surface crust is composed. Of all these agencies, only the last mentioned is preventible; protection against the others consists in minimizing their effects.

The term dust as applied to roads usually implies such of the material as is raised from the road and blown about, and the objectionable features of the dust situation are largely in this connection. If it were possible to confine the dust to the road surface it would act as a cushion between the road and the traffic, and protect the road from many of the agencies tending to its destruction. The annoyance caused by the clouds of dust now lifted and transported from the road would be eliminated, and the dust would be a benefit to the road rather than a nuisance. As it is, the dust generated on many heavily travelled roads is so offensive as to make driving along them or living near them, unpleasant and unhealthy, and to render unfit for use the products of fields and orchards adjoining them. Apart then, from the increased life of the road and the decreased cost of maintenance there are other benefits resulting from the suppression or prevention of dust, and these benefits are most felt by those who come into daily contact with the roads.

Suppression of Dust

All being agreed that the prevention of dust is very desirable, the means by which this object may be accomplished may next be considered. The problem of the selection of suitable dust preventives and the most economical and effective employment of such materials as are chosen, form one of the most important subjects of modern highway engineering practice. Not only must the formation and dispersion of dust be prevented, but such methods must be employed as will give the greatest returns for the money spent. As the benefits of many of the methods of dust prevention in common use are of a temporary nature, it follows that before any comparison can be made, the items of cost of treatment, life of results, and effectiveness in dust prevention must be carefully considered in their relation to each other. Generally speaking, for a given finished road surface requiring treatment, the material and the method of application which will maintain it in as nearly a dustless condition as possible at the least cost per square yard per annum, is to be chosen.

Cure and Prevention

There are two methods by which dust may be prevented from rising, which may be classified respectively as cure and prevention, firstly the application of such substances to the road surface as will hold down the dust formed, and secondly the employment of such methods and materials in construction, or the treating of the finished road surface in such a way that the formation of dust will be reduced to a minimum.

The first method consists of applying various liquids such as water, salt solutions, light oils, light tars, and oil and tar emulsions, to the road, the particles of dust being held together by the surface tension of the liquid. Benefits resulting from thus treating the road are only temporary, and repetitions of the treatment are necessary at intervals depending on the character of the liquid, the condition of the road surface, the nature and intensity of traffic, etc. Water has long been used as a dust layer, but its rapid evaporation, and the comparatively high cost of obtaining continuously satisfactory results render its use on country roads both unprofitable and unsatisfactory. Granulated calcium chloride has been used as a dust preventive for a number of years, and under certain favorable conditions, has given excellent results as a temporary dust layer. It is purchased in the powder form and is applied in the dry state or in solution. Its dust-laying qualities depend on its ability to absorb and hold moisture from the atmosphere, thus keeping the road surface constantly moist. In humid climates its use is attended with considerable success, but in dry localities subjected to little rain, and a dry atmosphere, additional sprinkling with water will frequently be necessary.

Oils and Tar

Emulsions of oil and tar have been used to a considerable extent as dust layers. In the process of classification the oil is treated with some alkali or other saponifying material, which renders it capable of mixing with water. In this way the oil may be diluted and applied to the road in small quantities, at the same time covering the entire surface. Results of such treatment are, however, not lasting, and several applications per season are required. Light oils having either a paraffin or asphaltic base are also used for dust laying, their benefits also being only temporary, the length of time during which an application will retain its effectiveness depending on the factors mentioned.

The foregoing materials for dust prevention are now giving way largely to the use of heavier asphaltic

* Asst. Engr. Ontario Department of Highways.

oils, which, in addition to their dust-laying properties, contribute to the bond of the road. The asphalt, which is usually from 40 to 60 per cent. of the total, remains on the road and penetrates the surface to a certain extent after the volatile constituents have evaporated, and assists in binding the surface. With a good grade of asphaltic oil, on a moderately travelled road, one or two applications per season will usually suffice, and later applications, owing to the retention of a part of the oil on the road may be made lighter than the first.

The value of an oil as a dust preventive is gauged largely by the quantity and quality of the bituminous base retained by the road after the evaporation of the volatile parts. The base of mineral oils used for this purpose vary from almost pure paraffin to almost pure asphalt. The paraffin in these oils has no value as a permanent binder, and oils containing a pure paraffin base or one containing a relatively high proportion of paraffin to asphalt, are used only as temporary binders or dust layers. The asphaltic base is, however, a true binder, and each application of oil containing an asphalt base provides the road with a certain amount of real binding material. The lightest grades of refined tar are also used extensively in the surface treatment of roads. In the case of these materials there is also a certain degree of penetration into the road surface and the results of such treatment may be considered as partially permanent.

For best results and lowest costs in dust prevention and road preservation it is necessary to start on a well-built road. Thorough consolidation and binding of the stone will prevent the internal movement which is so productive of dust, while a good crown will shed the water which would otherwise lie on the surface and soften the stone, making the work of attrition by traffic so much easier. First-class construction is the first and greatest essential as a basis for efficient and economical maintenance.

Sweep Before Oiling

The practice of applying oil to a thick coat of dust on a road surface, while affording temporary relief, is not economical financially nor will it yield satisfactory results. A small application of oil to the dust will keep it down only until the traffic has brought the dry dust to the surface, while the use of sufficient oil to hold down the whole layer of dust will entail unnecessary expense, and worse still, will produce a surface with objectionable features almost, if not quite, as bad as those of the untreated dust. In wet weather the dust, oil, and water will churn into a most offensive and injurious mixture that will indelibly soil any clothing, carpets or other textile goods with which it may come in contact. In commencing the oiling of a stone road the dust should be removed as completely as possible. Not only swept off the road, but in cases where it is liable to be blown back it should be carted away. For the purpose of cleaning the road of dust preparatory to oiling, a horse-drawn rotary sweeper which may be purchased at a cost of about $275 is almost indispensable. The actual cost of sweeping is very little, and will soon be repaid in the saving of oil and the better results obtained.

Oil the Second Season

Oil must never be applied when the road is wet or even damp. An almost insignificant amount of moisture on the surface will prevent adhesion between the oil and the road and failure is sure to result. Neither should oil be applied to a newly built macadam road until the stone has become thoroughly set. While protecting the road after setting has taken place, it appears to retard this setting when applied before it is complete. Best results are frequently obtained from leaving the road to thoroughly harden during the first season and commencing the oiling during the second. Whenever possible oil should be applied in warm weather. Whether the oil is heated or not, the heat of the road will increase its fluidity and permit greater penetration. When applied during cool weather it thickens on the road surface and is picked up by vehicle wheels and horses' feet, and its benefits are largely lost.

Penetration into the road surface is one of the most important factors in road oiling, and all means should be adopted to assist it. After the oil has been applied the road should, if at all possible, be closed to traffic for several hours in order that this penetration may proceed undisturbed, and the maximum benefits derived from the oiling, with the minimum inconvenience to the users of the road.

Application

Methods of applying oil are numerous, the original one being that of sprinkling by hand with ordinary sprinkling cans. This method is slow, inefficient and wasteful of oil and labor. It is impossible to secure a uniform treatment without using more oil than would be necessary to obtain like results when the oil is distributed by mechanical means. Mechanical sprinklers are of two kinds, gravity and pressure. The gravity sprinkler is the more common, probably because the cheaper. For the lighter oils an ordinary water wagon with sprinkler attachment will serve. With the heavier oils and tars, a pressure sprinkler should always be used. The pressure sprinkler is usually operated by a pump driven by the axle of the wagon or truck carrying the tank, and the oil or tar is delivered in the form of a spray. The velocity at which the oil strikes the road assists the penetration and much better results are obtained than with the ordinary gravity methods.

Heating

Whether an oil will require to be heated will depend partly on its percentage of asphalt, and partly on the weather. On a hot day an oil containing as much as forty per cent. asphalt may be applied cold, but even when the oil will run freely, better results will be obtained by heating it. In heating oil, care must be taken not to overheat it. Specifications for the use of a given oil usually state the temperature at which it should be applied, and this temperature should never be exceeded.

Quantity Necessary

The quantity of oil applied should be carefully watched. An insufficient quantity will not accomplish the desired results, while too much is not only wasteful, but leaves a surplus on top which is harmful to anything it touches. The quantity should be such that the surface is completely covered, and no more. This quantity will vary with the fluidity of the oil and the condition of the road surface. On a smooth surface, from which the dust has been well cleaned, the amount required will be a minimum; with a light oil, the entire surface may be covered with an application of one-eighth gallon per square yard. It is hardly to be expected, however, that such an application will prevent dust for an entire season; several applications may be necessary, but the cost will still be reasonable, owing to the moderate quantity used at each application.

A light sprinkling of sand over the oil when first applied will take up any excess of oil and prevent it adhering to vehicle wheels, etc. When the oil has penetrated the road any excess of sand may be swept off. Costs of dust suppression with light oils vary between wide limits, owing largely to the indiscriminate manner in which they are frequently applied. On many country roads a single application of forty per cent. asphaltic oil will keep them fairly dustless for an entire season, at a cost of from one to one and one-half cents per square yard.

Disintegration of Bare Spots

In order to continue the benefits of road oiling, care must be taken to keep the surface covered. Bare spots must not be allowed to develop or pits will form.

Experience has shown that where the stone becomes bare, disintegration is more rapid than in the case of the untreated road. This is due to the fact that the oil has prevented the penetration of moisture to the road. In the case of an untreated road, the surface will absorb a certain amount of moisture which is necessary to maintain the bond. Proof of this is seen in the ravelling of many macadam roads during continued hot, dry weather. When oil is applied it takes the place of the moisture and the surface bond is maintained, and even improved. When the oil is worn from the surface, the stone beneath, robbed of its bond, will rapidly ravel, and a pit in the road is the result. The scheme of road maintenance should provide for a frequent and systematic inspection of all oiled roads and the application of a small quantity of oil to any spots where bare stone is showing.

Carpet Coat

The second method of dust prevention on finished roads is prevention in fact as well as in name. Whereas the materials already enumerated are more for the purpose of holding down dust which has already formed, the more effective plan aims at preventing the formation of the dust. This consists of covering the entire surface with what is known as a carpet coat of heavy asphaltic oil or medium grade tar, filled with stone chips free from dust. This results in a surface from one-eighth to one-half inch thick composed of stone chips and a bituminous binder, the object of the stone being to take the wear of traffic, and of the bitumen to bind the stone together and hold it on the road.

While more expensive than the application of light oils, the carpet coat is usually more economical in the end, since a single treatment will last several times as long. When properly applied a carpet coat of bitumen and stone chips may last, with a small amount of maintenance, for from two to five seasons, providing a road which has many advantages equal to those of a bituminous macadam road. In some respects a properly constructed macadam road with a bituminous carpet coat is to be preferred to one with several inches of bituminous-bound surface. The cost is less, being equal to that of an ordinary macadam road, plus eight or ten cents per square yard. The body of the road, if built on a firm subgrade is perhaps more rigid than the bituminous macadam, owing to the danger in the construction of the latter type of using an excessive quantity of bitumen. This is particularly true of country roads, where experience in the use of bituminous binders is not so extensive as in the case of city streets. If the road is systematically maintained, the only work and material necessary are those required for keeping the carpet coat in good condition, the correct practice being to mend any defects in the surface before the body of the road is injured. This follows the principle of maintenance of city streets, where the concrete base is considered permanent, and the wearing surface, of whatever character, is renewed as occasion requires.

Application

The successful application of a carpet coat depends on a number of things, among the most important of which are the thorough cleaning of all dust off the road so that the bare stone is exposed over the entire surface, and the taking up of all the bitumen with stone chips. The first condition is necessary to secure the adhesion of the coat to the road, while the second prevents the creeping of the carpet coat in hot weather and the consequent formation of lumps. Of recent years the tendency has been to apply the carpet coat as thinly as possible in order to prevent any danger of creeping. This is accomplished by using a somewhat lighter oil or a lighter grade of tar, which permits of distribution in a thinner layer.

In order to obtain best results, a warm day should be selected for the application of the bitumen. If the application is made in cool weather it will be found to have become cold and thick before it has had an opportunity to penetrate the road, and peeling will probably occur. Also, the stone chips used in covering will not go into the bitumen as they should, and much "bleeding" on subsequent warm days will result. The application is best made by means of a pressure sprinkler, which assists penetration by forcing the bitumen onto the road at a considerable velocity. Both horse-drawn sprinklers and motor-trucks are used for this purpose, the latter giving the better results, being more easily regulated as to speed and discharge, and covering the ground more expeditiously.

Adhesion to Old Surface

As results are to a considerable extent dependent on the degree of penetration, or at least on the adhesion between the bitumen and the road, it should, if possible, be left undisturbed for some time after being applied. This is where a warm day assists materially in the operation. On no account should any traffic be allowed on the road before the application of the stone chips. The bitumen will adhere to wheels and horses' feet, and when permitted, the results may usually be seen in the subsequent removal of that part of the bituminous coat which has been disturbed. Frequently, where such disturbance has occurred, the tracks of vehicles may be distinctly seen, several weeks later, in bare strips where the carpet coat has worn off or scaled off. Most of the bare spots which develop shortly after a road has been treated in this way are due to one of two causes: insufficient cleaning of the stone before application of the bitumen, or disturbance of the bitumen before it has had a chance to adhere firmly to the surface of the stone. If it is impracticable to keep the traffic entirely off the road, only one-half the width should be treated at a time.

The size of stone chips required will depend on the grade of bitumen used. For the heavier grades of asphalt and tar used for this purpose half-inch chips are preferable, while with the lighter tars and asphaltic oils, quarter-inch stone or coarse sand will give better results. Whichever size of stone is used it must be free from dust. As the stone chips or sand is to compose the actual wearing surface of the road it must be carefully selected and as carefully applied. Wherever obtainable at a reasonable price, trap or granite chips should be used. First quality limestone is next in preference, while pea gravel and coarse sand, if of good quality, may also be used.

Oil Content

Considering first the application of the heavier oils and tars to road surfaces, the bitumen is distributed at the rate of one-third to one-half gallon per square yard, and after allowing it to penetrate to as great an extent as possible, half-inch stone chips are spread over the entire surface, in quantity sufficient to provide a layer from one-third to one-half inch thick. Since the success of the treatment and the prevention of creeping depend on the consolidation of the stone, it must be rolled, and warm weather during the period of rolling is of great assistance in obtaining a maximum consolidation. During the process of rolling the stone is forced into the bitumen, which comes to or near the surface. The principle on which the rolling is done is that the voids in the stone shall be reduced to a minimum, and these voids be filled with bitumen. If the voids are not as small as possible there is an excess of bitumen which will come to the surface and cause "bleeding" of the road in hot weather, when, assisted by the crown of the road it will tend to run toward the sides and cause lumps. The roller should make several passages over each portion of the road, and fresh stone should be applied wherever the tar or oil comes to the surface.

In order that running of the bitumen may not occur, a number of conditions must be complied with. First, the bitumen must not be applied in larger quantities than just sufficient to cover the road. Care must be taken that it is heated to the correct temperature, else its viscocity will requirè a larger amount to be used than is necessary or advisable. Sufficient stone must be used to take up all this bitumen, so that no free bitumen will remain on the surface. Rolling must be thoroughly done in order to reduce the volume of the stone to a minimum, and the rolling must take place before the road has cooled to such a degree that the bitumen will not flow freely between the particles of stone. If work of this character is done in cool weather the surface is almost sure to run and bleed badly in ensuing hot days. If the foregoing precautions are observed, a satisfactory surface should result, with creeping eliminated.

Cost

The cost of a heavy carpet coat such as described will usually be from eight to ten cents per square yard, and the life of such a coat, with careful though not expensive maintenance, is estimated at from two to five years. Including the cost of maintenance, the annual cost of this form of road protection in ordinary cases will be from two to four cents per square yard. The cost will be somewhat increased on main travelled and suburban roads, in which case it may be as high as six or eight cents per square yard per annum.

As the tendency to creep depends largely on the thickness of the carpet coat, and as this tendency constitutes one of the main objections to this form of road preservation, recent practice has changed somewhat to a preference for a thinner coat composed of a lighter grade of asphaltic oil or tar, filled with smaller stone chips or coarse sand. The durability of such a treatment is not nearly equal to that of the heavier carpet coat, but the lower cost at which it can be applied will permit of more frequent re-surfacing. It possesses the additional advantage that rolling is not absolutely necessary, and the cost of this item may be eliminated.

The cost of the latter treatment, using approximately one-quarter gallon per square yard and covering with sand is ordinarily from three to four cents per square yard. With ordinary country road traffic this treatment will last a full season, and in most cases a moderate amount of repair work will make it good for a second, making an average cost of from one and one-half to three cents per square yard per season, or somewhat less than the usual cost of the heavier treatment.

The Increasing Use of Electricity

The Electric Road Roller in England Proves to be Cheaper, Cleaner and More Economical than Steam or Gas Rollers

By A. Jackson Marshall

The subject of electric road rollers is one which has had but slight consideration in this country. England, more keenly alive to the possibilities of electricity as a motive power than ever before, has favored the electric vehicle for municipal service in many and varied ways, and an eminent English engineer has published in a recent issue of the London Electrical Times an account of his investigations and study of the feasibility of the electric road roller. England is growing accustomed to the electric vehicle and finds it satisfactory. That it is an ill wind that blows no good is quite applicable to the electric truck situation in England at the present time, and while horses and gasoline trucks during the early part of the war were commandeered in great numbers for transport service, electric truck installations have been greatly increased and many concerns that had formerly employed either horse or petrol equipment, have come to realize the superiority of electricity as a motive power for vehicles used in urban delivery and trucking industries of all kinds. With the cost of gasoline always high and now rising to prohibitive prices and the drastic measures which the English government has taken to prevent the gasoline supply from being entirely exhausted, it is reasonable to expect that England will turn to the electric vehicle which is dependent for its power on the great natural resource—England's inexhaustible coal supply. Municipalities have been forced to recognize the economy, simplicity, ease of operation and cleanliness of the electric and the result has been the adoption of this type for many forms of municipal service. As a result of the action taken by the board of health of the City of Manchester to forbid the maintenance of stables in urban areas, electric vehicles have been adopted in the place of horses in several branches of municipal work. Electric omnibuses, electric fire apparatus, electric vans for the collection of refuse, electric street sprinkling carts are all very extensively used in England already and now comes the electric road roller.

Increased Use of Electricity

During the past decade many material conditions have changed, though in every respect they are favorable to the utilization of electric road rollers in city and town areas. One of the changes is the greatly increased use of electricity, and another is the improvement of all common roads resulting from the increase of power propelled vehicles. Naturally in congested areas the unit stress on pavement is more acute, while the business aspect calls for a much higher degree of engineering capacity than that entailed by rural highways. Before 1865, when the steam roller was a nine days' wonder in Paris, horse rollers had been used which were for many reasons quite unsatisfactory. In 1869 and 70 the first discussions on the steam roller took place in Birmingham, England.

Weight and Speed

The pressure per square inch imposed on the road surface by the weight of the roller must, with water, be greater by 25 per cent. than that of the heaviest vehicles using finished roads. Where a 30-ton steam roller supplied this condition, the effect with water lubricant was to unduly crush the metal. With a 15-ton roller this destruction did not occur, but the pressure was insufficient. As a lubricant and binding agent, bitumen has modified very considerably these considerations.

The speed of rolling should not exceed 2.5 miles per hour, and the horse-power, for which no indicator diagrams seem to be available, appears to be roughly one horse-power per ton gross. If the commercial efficiency of an enclosed traction electric motor is taken at the convenient figure of 74.6 per cent., then for a 15-ton roller a 15 horse power motor equipment would require a specific discharge rate for its accumulator (storage battery) of 15 kilowatts. The weight of the battery carried by any vehicle, states the Electrical Times, depends upon the specific discharge rate of the cells employed. But in this case the ten hour rate favored by battery makers fits in with a ten hour working day favored by road roller attendants.

Today the first demand is for an 8 and 10-ton roller for bituminous work, particularly for a roller with short road base for transverse work and patching. Such a roller, if electrically operated, can stand and charge all night. It can be worked with one attendant with the utmost simplicity and the minimum of effort. At any time it is ready instantly to go out to its work, without that one hour to get up steam which is necessary for a small steam patching roller, and it can be designed to travel at a good speed when running from job to job over normal roads where traffic resistence is lower than upon the actual work.

Battery Capacity

Allowing for a minimum discharge at a ten-hour rate and a maximum, when rolling upon hills, at a three hour rate, an equipment of .75 kilowatts per ton is estimated. As the roller advances and oscillates over a given piece, there is a point of stop and reverse. This point has puzzled the steam roller makers and led them to produce at great pains a quick reversing link motion or other similar gear, whereby the halt at the change of direction may be reduced to the minimum. On this point electric control is especially favorable, and the point is most important because undulations form in the roadway where these halts have occurred. In electrical working, it is possible to cut off the current and allow the roller to decelerate while the motor has been switched to that connection which has changed its direction of rotation and started it to accumulate its effort in the reverse sense, all ready for an instantaneous reverse movement.

Even Surfaces

Because of the tendency to the formation of undulations or corrugations which develop later in traffic, due initially to these halts and reverses in rolling, three rolls in tandem have been advocated, instead of the time honored two side rolls and one center leading roll. In addition to this, the halt point, which, with a good operator should not be a repeated point, should also be varied by different pressure upon the three, or upon two rollers. Thus the unit downward pressure upon the leading roller would be appreciably lower than upon those succeeding it. This can of course be easily arranged in the design.

For city work neither steam nor gasoline propulsion could compete with the electric automatic road roller. All automatic controls undoubtedly increase efficiency and precision. The electric road roller lends itself to automatic control. At the same time automate control is likely to be a strong feature in urging common adoption of electric rollers. With steam and gasoline there are other inherent complexities, and automatic controls cannot be nearly so simple as in the case of electricity. The real reason, however, why automatic rollers have never been proposed is probably that only in the case of electric road rollers is the attendant not required continuously on the vehicle for purposes other than running control. Once the simplicity of electric driving and control is considered there follows naturally the simplicity of various means of setting the reversal distances and cross feeds, and the automatic road roller, with its obviously higher efficiency than with hand-feed and control, is the progressive result.

Advantages of the Electric

In addition to a type of electric roller weighing eight or ten tons, there is a demand in most cities for a four to six ton type. The latter would almost certainly be a one-man machine equipped with suitable materials as well as with heating and mixing trays and spraying devices, all complete for the repair of those numerous holes and ruts of one square foot upwards, which automobile drivers discover to their cost in every part of the road. There are few towns that would benefit markedly by two or three of these one man electric automatic repair rollers dressing continually the small pot-holes in the streets which are so injurious. These four ton rollers would be of about the same weight in the frame as the eight ton type, but lighter all around in the cells, rollers and motors.

On the whole there is no doubt that the low speed of rollers and short radius of service within a given area favor electric cells and propulsion. There is every evidence now of a demand for electricity in England to supersede steam and the more modern gasoline and oil types of road rollers. It is not a question of first cost of plant, or of operating costs, for modern cities are prepared to pay without exception, even should there be an increased charge, for healthful improvements and silent workings and cleanliness, to say nothing of more uniform wear after automatic rolling. Electric road rollers constitute an improvement over and an advance upon the noisy and dirty working of steam rollers.

Troubles in the Engineering Profession

Stricter Qualifications to Protect Both the Public and the Qualified Engineer from the Quack

By G. N. Houston, M.C.S.C.E.*

There is a growing tendency among certain engineers to attempt to remedy some of the troubles in the engineering profession by means of legislation, limiting those who can legally practise to engineers having certain qualifications.

The reasons advanced for advocating the licensing of the profession come under two classes—self protection and public protection.

Self Protection

We are all familiar with the Rodman, who having been endowed by nature with a vivid imagination, a superabundance of self-confidence and a glib tongue, hires an office, hangs out his shingle, fakes his experience and poses as a consulting engineer.

Should not the competent engineer be protected from this class of fakers? Doctors, lawyers and even school teachers are required to have certificates before they can practise. Why not the engineer?

The only grounds upon which we should ask the public for legislative control of the engineering practice is that of public protection. The public need protection because they are not in a position to judge of the ability of an engineer.

An engineer's ability must be inferred from either his education, his works or his membership in the strictly engineering societies.

Experience Necessary

If the problems of engineering design, construction and operation were merely matters of figures the man fresh from college would usually qualify as the best engineer. Many men leave our institutes with this view but soon find that long before the time for applying formulae is reached the scheme must be viewed by an engineer of sound judgment based upon long experience.

Diplomacy, tact and good judgment are so essential in all engineering operations that any attempt to judge an engineer by mere degrees and diplomas is likely to prove a failure. Can the public judge his ability by his works? Unfortunately popular descriptions of engineering works do not find their way into the public press except occasionally and the public does not read the engineering press. An engineer's works do not always indicate his ability. A badly designed bridge may stand for years a menace to the public and finally go down when the critical load comes on it. A dam may stand until a flood comes. It takes time to demonstrate the ability of an engineer by his works. Membership in Engineering Societies should be a good criterion by which to judge the ability of an engineer. In other words how does he stand in the profession? What do his associates think of him? They are in a far better position to correctly estimate his ability than the public in general.

Licensing Engineers

The Committee of the American Society of Civil Engineers, appointed to consider this matter, while reporting against the general principle of licensing engineers, realized that there were many engineers who favored the idea and that many very inferior acts had been drawn up and submitted to the law making bodies for enactment. Should some of these pass, licenses would be issued to men totally incompetent, thus deceiving the public instead of protecting them. The Committee, therefore, draughted a Model Bill to be used as a basis for proposed legislation. The Acts which have been proposed come under two classes.

(a) Those which attempt to license all in the profession.

(b) Those which apply to engineers practising only in certain lines.

Many difficulties are encountered in draughting an Act. The first trouble comes in defining to whom the Act applies. Especially is this true under the first class of bills.

In the Colorado Act submitted to the Legislature in 1910 the definition of the Civil Engineer was very broad.

Civil Engineering Defined

In 1914 the proposed definition of Civil Engineering was modified as follows:—

"The profession of Civil Engineering, within the meaning of this Act, embraces the design, inspection and supervision of construction, and reports on the safety, of public or private utilities which require experience and the same technical knowledge as engineering schools of recognized reputation require for graduation; provided, however, that none of the provisions of this Act shall apply to the practice of surveying, and, provided further that the provisions of this act shall be limited to the services of engineers in the design, inspection and supervision of construction, and reports on the safety, of any structure or works on any of the following kinds or classes of structure and works.

1. Bridges 16 feet or more in length or other structures requiring a determination of stresses and strains for their proper design, on public highways or roads open to the use of the public, or on steam or electric or other railroads.

2. Structures built of stone, plain concrete or reinforced concrete.

3. Structural steel structures including steel in buildings and similar structures when said buildings or structures are three or more stories in height, also steel in mill buildings, steel in grain elevators, steel in mine and mill structures, steel in industrial buildings, and steel in plants and steel in structures on ditches, canals, sewers, waterworks and power plants.

4. Canals, ditches and conduits having a capacity of fifty cubic feet per second or more.

5. Sewers and sewer systems and sewage disposal plants; water supply plants for domestic use, and power plants including power plants for irrigation.

6. Dams and reservoir embankments of a height of ten feet or more.

7. Mill and power plant buildings of timber, brick,

---

Abstract of an Address before the Calgary Branch Can. Soc. C. E.

concrete or any combination of these materials and electric transmission lines.

8. Timber bridges, trestles or structures for mill, mine and industrial plants, grain elevators, ditches, canals, sewers, waterworks and power plants.

9. No maps, plans, designs, reports, statements or filings to be certified or approved by an engineer shall be accepted or filed by any State official unless the certification or approval is executed by a person duly licensed in accordance with the provisions of this act.

It is a serious question whether a license law really excludes the incompetent man from the profession. There are quacks still practising in the medical profession and incompetents in the legal profession in spite of the Acts governing the practice. It is suggested that strict government supervision of plans, specifications and construction of all structures where the safety of the public is involved, combined with laws requiring a high qualification for engineers at the head of the departments, will result in a more effective public protection than any legislative attempt to control the engineering practice.

The qualifications for the heads of departments requiring engineering knowledge should provide for (1) a minimum residence in the country, province or state in order to ensure familiarity with local conditions. (2) Membership in one or more of the three National Engineering Societies—Can. Soc. C. E., Am. Soc. C. E. or British Institution of Civil Engineers. The requirements for admission to the grade of Member in all of these Societies are high and the tendency is to stiffen the requirements. (3) A minimum amount of experience in the particular line of engineering, a knowledge of which is required in order to fill the position. The above suggestion has greater possibilities in it for public protection than any system of licensing engineers. The proper method of handling the fake engineer is through the local branches of these national societies. His record can be investigated by them and shown up.

In addition to the above these local branches can do a considerable amount of advertising which would be considered unprofessional on the part of the individual to the end that the public may be kept in touch with engineering matters and be made to realize that membership in these societies represents high qualifications as an engineer.

ANGUS + ANGUS, ARCHITECTS,

New Eight Room Public School for Cochrane, Ont.

NORTH BAY & SUDBURY

In spite of frequently repeated statements that building is at a very low ebb, there are very encouraging evidences that many private individuals, municipalities, school boards, etc., are now going forward with work that has been temporarily delayed. This is no doubt due to a gradually increasing confidence in the outcome of the war, but even more, we believe, to the quite remarkable demonstration of Canada's stability, both financially and industrially, which has been so much in evidence since the war began.

A good example of this renewal of building, temporarily held up, is that of the public school in Cochrane, Ont. This was planned in 1914, architects were appointed, and everything was in readiness when the war decided the municipality to wait. The returning confidence is shown in the call for tenders which has just been sent out. This town, too, is itself typical of Canadian development, in that, though quite recently placed on the map, and known to most of us only by hearsay, an eight-roomed school building is being erected.

The school is approximately 96 by 65 feet over-all dimensions. The main exterior and interior carrying walls are solid brick; the construction is wood joists with bearings on steel or brick walls in every case. The exterior facing is red pressed brick with galvanized iron copings and cornices.

The foundation walls are concrete 20 inches thick, on 48-in. concrete footings. The basement floor and interior carrying walls to a height of 4 ft. are also concrete, the remaining walls being solid brick.

The building is two storeys and basement, laid

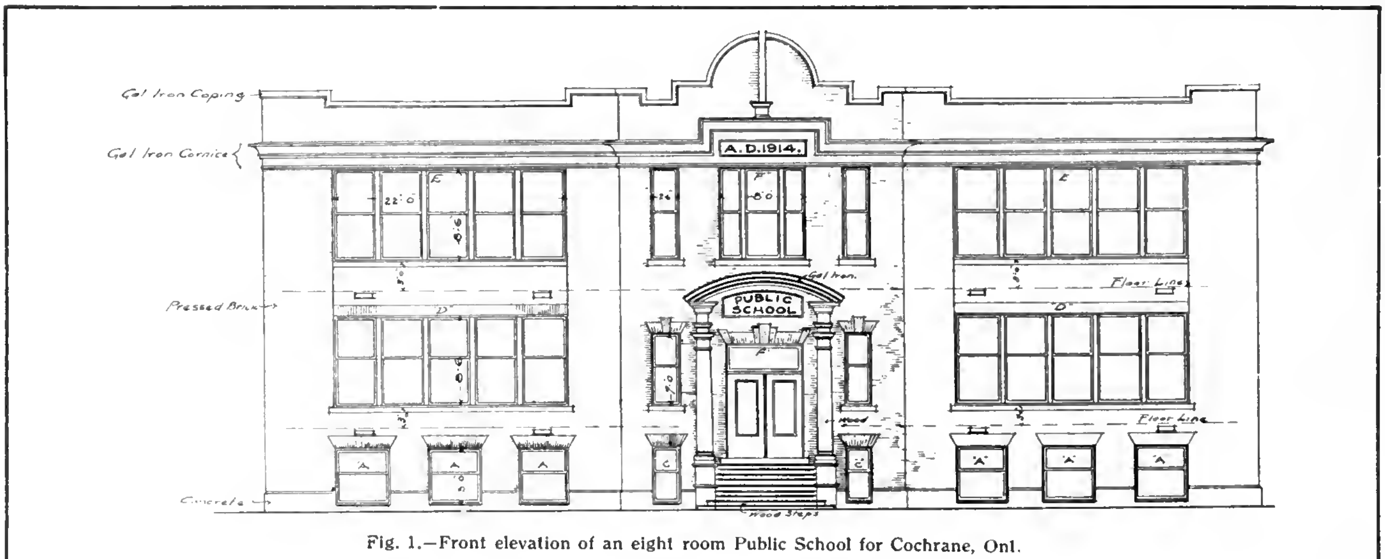

Fig. 1.—Front elevation of an eight room Public School for Cochrane, Ont.

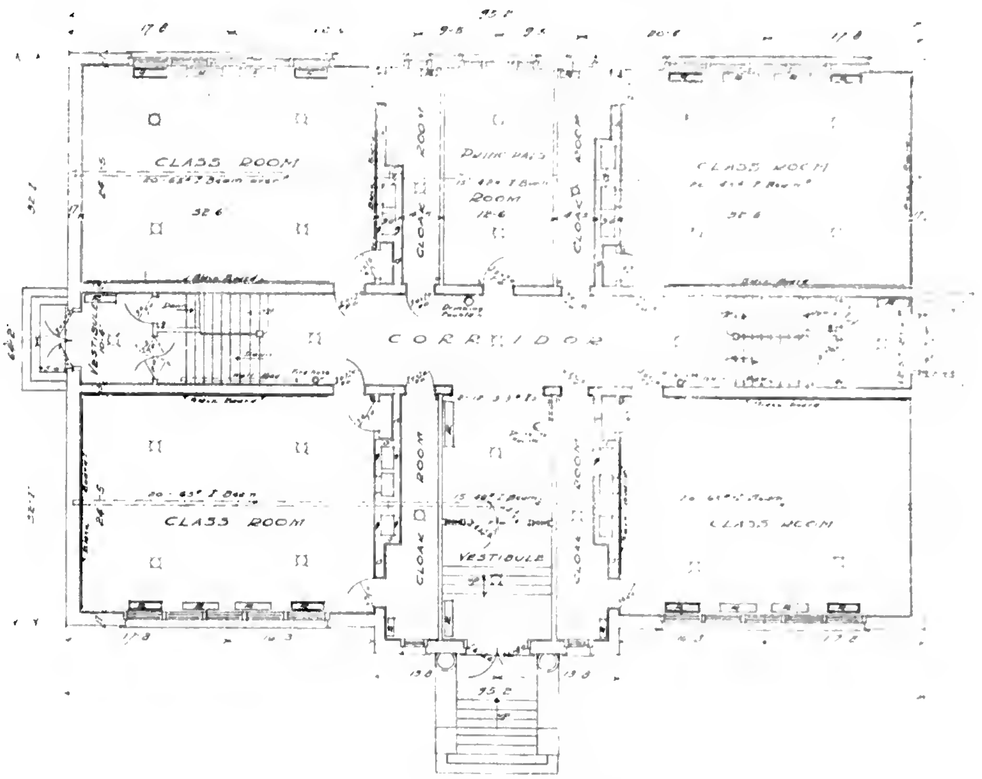

Fig. 2.—Ground floor plan, Cochrane School.

out uniformly with a main corridor on each floor across the building, with class-room in each corner.

The basement plan shows four large play-rooms, each approximately 25 by 33 ft., fuel room, boiler room with two boilers for the one-pipe, gravity, low-pressure steam heating, and the individual lavatories.

Wooden steps, a small portico surmounted with wooden pillars and a cast-iron coping, lead to the main entrance which opens into a large vestibule somewhat below the ground floor level. There are also two side and a rear entrance. The principal's room is directly opposite the main entrance, on the opposite side of the corridor. Four class-rooms 32 ft. 6 ins. by 24 ft. 6 ins., with separate cloak-rooms for each, account for the remaining floor space.

Sewage Treatment at Milwaukee, Wis.

Results of Two Years Exhaustive Practical Experiments on the Activated Sludge Process

By T. Chalkley Hatton

Exhaustive experiments on the activated sludge process of treating sewage to determine the best method of securing a uniform diffusion of air have been carried on at Milwaukee, Wis., for the past two years, under the direction of T. Chalkley Hatton and W. R. Copeland, of the Milwaukee Sewerage Commission. The following notes, giving a short summary of the process and the results of experiments, are abstracted from a paper by Mr. Hatton before the Illinois sections of the American Water-works Association and the Society of Engineers and Surveyors.

The plant has been equipped with the best apparatus available to determine the volume of sewage treated, volume and rate of air applied, and the making of the chemical and bacteriological investigations. It has been run continuously night and day, always with skilled supervision on duty.

Early in March of 1914 laboratory experiments were begun by using two glass tubes 6 feet long and 1¼ inches in diameter. At the bottom of one a filtros plate was inserted through which the air was passed and diffused. A small glass tube was placed inside of the other tube, and carried to near the bottom of the latter. Through this smaller tube the air was discharged from an orifice and diffused throughout the mixture of sludge and sewage contained in the large glass tube.

Experimental Plant

This experimental plant was erected and operated simply to secure information necessary to design a larger outside tank for trying out the process, and also to observe the difference of the effect of diffusing the air through a porous plate and open orifice.

The second series of experiments were conducted in a tank (improvised from a chemical precipitation tank), 32 ft. long, 10 ft. 6 ins. wide and 10 ft. deep, having a volume, when in operation, of 22,200 gals. In the bottom of this tank there are 51 filtros plates set in castings. The plates are 12 ins. square and 1½ ins. deep. The ratio of plate surface to tank surface is about 1 to 6.6. The coarse screened sewage is discharged directly from an orifice box (in which its volume is measured), in one end of the tank. The effluent is drawn off by means of a floating circular weir.

This tank was put in operation on May 6, 1914, and was continuously operated until November 24. Numerous variations were made in the cycles, volume and rate of air, but, under normal conditions, the cycle was as follows:

Filling 1 hour, aeration 3½ hours, settling ½ hour, drawing 1 hour. As soon as filling began the air was always turned on for the purpose of blowing the precipitated sludge off of the top of the filtros plate before the full head of water, when the tank was full, made the operation more difficult; thus the average aeration period was 3 hours only.

The third line of experiments was conducted in two inspection tanks 10 ft. deep, 5 ft. wide, by 1 ft. between sides. In each of the sides glass windows were inserted to permit of observing the action of the liquid during the several operations.

These experiments were conducted from June to the middle of November and gave us some very valuable information.

The fourth line of experiments was carried out to test the process by the continuous flow method. The tank used was the same size as, and built alongside of, the tank in which the second series of experiments was conducted by the fill and draw process. It was 32 ft. long, 10 ft. deep and 10 ft. 6 ins. wide. One-sixth was divided off at one end for the sedimentation chamber, and the balance was divided into a continuous channel about 3 ft. 4 ins. wide and 81 ft. long, at the bottom of which 42 filtros plates were set in castings, and air delivered to the underneath side of the plates. This tank was put in operation (after securing activated sludge), the first of August, and has been in continuous operation to date, with the exception of necessary shut downs due to the break down of the main sewage pumping station.

Many series of experiments have been conducted with this tank. The volume of air has been varied from 1 to 3 cu. ft. per gallon of sewage treated. The rate from 75 to 200 cu. ft. per minute. The rate of flow from 22,000 gals. to 74,000 gals. per 24 hours, or from 14 hours to a little less than four hours' running through period, and a great many observations made for controlling the sludge feed and the effects upon the process by varying volume of activated sludge.

The sewage treated has been taken from the main intercepting sewer serving a population of about 275,000, to which is added the liquid wastes from the packing house district, tanneries, breweries, and other large and varied industries.

Its average characteristics for the year have been as follows: 16.3 cu. yd. of solids per million gallons settleable in 2 hours; 259 parts per million of suspended matters, varying from 150 to 600 parts, 1,109 parts of total solids; 32.9 parts of organic nitrogen, 125 parts oxygen consumed; 2.2 parts of dissolved oxygen, and 1,461,000 bacteria per cubic centimeter at 20 degs. C. Temperatures have ranged from 44 degs. to 70 degs. F. The variation of flow and strength of sewage throughout the average week is approximately 82 per cent.

Air Diffusion

We feel that the best method of diffusing air has not been determined, although there are many available. As the use of this process becomes general this problem will no doubt be satisfactorily solved by progressive means.

The open air jet reduces the loss of air pressure, but reduces its efficiency owing to the size of the air bubbles produced. This objection may be overcome by reducing the size of the orifice.

Another objection we found to the open jet is its tendency to clog the air feed pipes with sludge drawn into the pipe when the air is shut off for any reason.

The monel metal cloth has only been tried out for about a month, and has proved quite satisfactory. Although, much more porous than the filtros plate, it produced smaller bubbles, due probably to the fact that the surface of the cloth was smooth and the air, while building the bubble, could not adhere to the surface as it does to the rough granular surface of the filtros plate.

Kisselghur was tried out. This gave the smallest bubble of any other agent tried, but the initial frictional loss sustained in getting the air through a plate ½-in. thick was 20 lbs., which made this diffuser impracticable owing to cost.

Filtros Plates

The filtros plates, if furnished of uniform porosity, have given the most satisfactory results, but they have a few characteristics which should be realized.

It is of the greatest importance that the agent used shall diffuse the air uniformly per cubic foot of liquor, therefore great care should be taken in getting a diffuser of uniform porosity. So far this has not been possible with the filtros plate. Out of 780 plates tested for our new 2,000,000-gal. plant, where we specified a plate which would pass 2 cu. ft. of air per minute under a 2-in. water pressure, and allowed a 5 per cent. variation either way, 35 per cent. of the plates received were rejected and only 27 per cent. came within the strict terms of the specifications.

Tests made with the plates used showed that when wet the initial loss of pressure due to passing the air through the plate under 5 lb. pressure was ¾ lb., and for every cubic foot of air per minute per square foot of surface passing the plate there was an additional loss of ¼ lb.

There are two ways of overcoming this great frictional loss, and the factor is an important one to consider in large plants. One is by reducing the thickness of plate to, say, ½ in., and reinforcing it with wire similar to window glass reinforcement; and the other is by soaking the plate, before use, in a mixture of paraffin and benzine, blowing with air until the paraffin appears at surface of plate. This establishes fine pores through the plate, which are coated with a non-absorbent, permitting the air to pass with the least friction and the paraffin impels the water so that the plate does not become waterlogged.

We have been operating filtros plates for nine months under all sorts of conditions, and have observed no difficulty in keeping the plates from absorbing the solids in the sewage, or becoming clogged on the underneath surface. It may be possible for the pores to become filled in time with bacterial growths, which may be removed by forcing heated air through them.

It is necessary, however, to filter the air before delivering it to the plate to prevent dust and dirt from reaching it. This is done by passing the air through a filter composed of excelsior built into the feed line.

The efficiency of the air varies almost directly as the size of the bubbles. We call the critical diameter ⅛ in. Below this size the efficiency increases very rapidly and the reverse is true for bubbles over this size.

There are three factors of special importance to be considered in choosing a diffuser agent. First, the smaller the air bubble produced the greater the efficiency. Second, greater density increases the frictional losses, and hence the cost. Third, the tendency to absorb and retain sludge, or to permit it to reach the underneath surface of the diffuser tends to reduce the efficiency of the diffuser, and allows sludge to precipitate on the top surface of the diffuser.

Functions of Activated Sludge

Activated sludge accomplishes four principal functions: The clarification of the liquor, removal of the putrescible organic matter, reduction of bacteria and finally, if the process be continued for a sufficient period, oxidizes the ammoniacal compounds into nitrates. Therefore, one of the first steps in designing a plant in which this process is to be employed is to determine the degree of purification required, following which the question arises as to efficiency, volume of air required, period of application and volume of activated sludge necessary to be kept in retention with the raw liquor.

Our problem in Milwaukee embraces the clarification of the liquor, securing an effluent stable for five days, the reduction of the suspended matters 90 per cent. and 95 per cent. removal of bacteria at 20 degs. C. With our continuous flow tank we have secured this average effluent for months by using 1.75 cu. ft. of air per gallon of sewage with 4 hours' aeration, 20 per cent. activated sludge and from 10 to 15 minutes' sedimentation period. Basing these results upon the operation of a 50,000,000-gal. plant, the estimated cost will be $4.38 per 1,000,000 gal., including all overhead and boiler room charges, but excluding engine room and plant attendance, and the cost of disposing of the sludge.

There appears to be no difference in the results obtained by carrying out the process either by the "fill and draw" or "continuous flow" methods considering volume of air applied per gallon, cost of aeration and volume of activated sludge required; but measured in terms of cost of construction and operation the "continuous flow" is the superior method. With a wide variation in strength of liquor and rate of flow a more uniform standard of effluent can be obtained from the "fill and draw" method because it is susceptible of better control, which is true of all "fill and draw" processes.

In order to maintain clarification and stability, and remove at least 95 per cent. of the bacteria from the Milwaukee sewage we have found it necessary to carry on the nitrogen cycle far enough to develop from 3 to 5 parts of nitrates. This has not been at all difficult to maintain.

Effect of Low Temperature

Low temperatures are not going to affect the process as much as we had anticipated. We believe, however, that the effect of such low temperature continuing over long periods may be easily overcome in one or two ways; either by adding more air, or a higher degree of activated sludge, or both. Thus the trouble can be overcome without excess tankage.

If more air is applied for a greater period, of course the nitrates are greatly and rapidly increased. This increases the value of the sludge. Whether this increase will pay for the additional air used is a matter yet to be determined.

The most economical ratio between diffusing surface and tank surface has not been definitely determined. Our ratios run from 1 to 5.0 to 1 to 8.5. There appears to be no appreciable difference in the results obtained. We are inclined to the belief, however, that a much greater ratio would reduce the efficiency by permitting more air to escape without giving the liquor the maximum opportunity to absorb it.

While all of our experiments have been made upon tanks holding 8 to 10 ft. of liquor, our supplementary experiments indicate that more efficiency of air can be obtained in deeper tanks by reason of the longer contact period between the air and liquor, and the tendency of the air, as it escapes from the diffuser, to break up into smaller bubbles because the pressure head upon it has been increased. Local conditions might, and probably would, largely control the depth of tank.

Volume of Air

The purification of sewage obtained varies decidedly with the volume of air applied. Small volumes applied for five or six hours do as well as larger volumes applied for three or four hours; but the time of aeration required to obtain a like effluent does not vary directly with the volume of air applied per unit of time. For instance, air applied at a rate of 2 cu. ft. per minute purifies the sewage in less time than 1 cu. ft. of air per minute, but will not accomplish an equal degree of purification in one-half the time.

There is also a limit to the volume of air applied per period of application below which it is not possible to secure any significant degree of purification. If less than 1 cu. ft. of air per gallon of sewage treated be applied for a period of four hours the degree of purification of the Milwaukee sewage rapidly decreases until little or none is effected; but, if the period of application is continued long enough, this rate of air will produce any degree of purification required.

In view of the fact that the air is the most important item of cost in the operation of the activated sludge process, we tried out many experiments with a view of determining the effect of decreasing the period of aeration and rate of application.

Data on Unit Quantities

Our experiments so far indicate that with 15 ft. deep rectangular tanks 15,000,000 gals. of sewage can be treated per acre of ground covered, which includes influent and effluent conduits, sedimentation and sludge tanks, and that the cost of such tanks, including influent and effluent conduits, pipe foundations and all piping, will be approximately $18,000 per 1,000,000 gals. This cost is based upon our local conditions where the tanks have to be built out into the lake and supported upon piles 40 ft. long with 4 ft. centres.

The sedimentation period required to reduce the suspended solids to 10 to 12 parts per 1,000,000 is from 10 to 25 minutes; the latter seeming to be a maximum with low temperatures.

We now come to the consideration of the sludge, and it is interesting here to describe how the percentage of activated sludge in contact with the liquor is determined.

We speak of maintaining a certain percentage of this sludge with the sewage during aeration, and in order to establish a unit which is easily determined we have fixed on that volume settling during one-half hour. It is true this is an arbitrary determination, but it is logical, nevertheless. From a great many determinations it has been found that 78 per cent. of well activated sludge will settle out of the mixture in one-half hour, and that during the next one-half hour the addition is but 4 per cent. It is desirable in operating the plant to determine frequently the volume of this sludge in contact with the liquor. One hour is often too late to get the most benefit from any change demanded. This sludge, so settled out, has about 98 per cent. moisture content, and it is desirable to return this sludge to the raw sewage with as little water content as practicable, because the more water the more tank area required.

To get this result it is necessary not only to let the sludge settle for at least one-half hour, but to put it under a pressure due to a head of water over it. In our new tanks we let the sludge from the sedimentation tank settle to the bottom of a 4-ft. chamber built under the tank 35 ft. deep, from whence it is pumped out after being compacted by a head due to 34 ft. of the liquor over it. Then it is further aerated in reservation sludge tanks, again settled, and pumped from the bottom of the second sludge settling tank to the raw sewage.

From our experiments we find that under a 26-ft. head of liquor the sludge will be de-watered in one-half hour from 98 per cent. to 94 per cent. and lose 40 per cent. of its volume. If a 94 per cent. rich activated sludge can be mixed with the raw sewage as it enters the aerating tanks, the size of these tanks can be materially reduced. By extra aerating the sludge to be returned to the raw sewage it is believed that the volume of air required to treat the raw sewage will be diminished. Thus the cost will be decreased because it will require only one-fifth of the volume of air to give this sludge the extra aeration (providing 20 per cent. of activated sludge is being maintained in the sewage tanks) as to give the whole body of sewage treated the same air treatment.

It has been demonstrated beyond doubt that the richer the activated sludge in nitrates the quicker the purification of the sewage and less air is required.

The sludge produced is quite brown in color, appears like pieces of finely divided sponge, and settles out of the quiet liquor very rapidly; 65 per cent. will settle in 10 minutes. It is readily drained on the ordinary sludge drying beds, requiring about one-half the time of well digested Imhoff sludge, but it acts quite differently. During the first hour the liquid drains through the bottom, the sludge gradually settling upon the surface seems to close the interstices of the bed and the liquid rises to the top of the sludge from which it can be titrated without disturbing the settled sludge.

With two days of dry, warm weather its moisture content will be reduced on drying beds from 98 to 82 per cent., and in two weeks the moisture will be reduced to 65 per cent.

The sludge seems to absorb the colloidal matter very rapidly. Highly colored liquor introduced into it will be decolored in a few minutes. It has no apparent odor. When well activated the sludge produced by the Milwaukee sewage contains from 14,000,000 to 18,000,000 of bacteria per cubic centimeter, from 5 to 6 per cent. of fats and total nitrogen in the form of NH_3 from 4.4 to 9 per cent. based upon 10 per cent. moisture. At the present market the value of this sludge when degreased and reduced to fertilizer, that is, dried to 10 per cent. moisture and ground, ranges from $10 to $20 per short ton.

The Milwaukee sewage produced on an average about 3,000 gals. of sludge per 1,000,000 gals. at 98 per cent. moisture. On the basis of 10 per cent. moisture it produces about ½ ton per 1,000,000 gals.

The cost of dewatering, degreasing and drying the sludge has not yet been definitely determined, but from a careful study of this question it is believed this cost will not exceed $6 per dry ton. Apparatus for performing this portion of the work has already been arranged for and will be installed in our new 2,000,000-gal. plant during the coming month.

General Conclusions

As far as we have progressed with our experiments upon the treatment of sewage by the activated sludge process nothing has occurred which indicates that the process is unreliable, unworkable or unduly expensive. We feel, however, that there are many engineering problems yet to be solved before the ideal plant can be designed. We cannot hope to solve all of these in the first plant built, but expect this to be done progressively as other plants are built and operated.

Roman Catholic School and Residence for Cote des Neiges, P. Q.

A contract for the construction of a boys' and girls' school and teachers' residences for the Cote des Neiges Roman Catholic School Commissioners has been let to Messrs. E. N. and U. Boileau, Montreal. The school, designed by Mr. G. A. Monette, architect, Power Building, Montreal, will be on a site on the Cote des Neiges Road, measuring 234 feet by 65 feet. The school proper is to be 162 x 65 feet, the residences for the teachers being situated one at each end. The building is to consist of a basement and three storeys. The exterior will be constructed of rustic brick, (supplied by the National Brick Company of Laprairie) and stone trimmings, on a steel frame; the foundations will be of concrete, with a Megantic granite base up to the first floor.

The three storeys will contain a total of 22 class rooms, each, on an average, accommodating 40 pupils. The school is to be separated into two sections, one for boys and the other for girls, and the division will be made by means of a terra cotta wall constructed through the centre of the building. There are separate entrances for each section.

The floors are to be of Seigwart concrete beams, covered with maple. The partitions of the class rooms will be of plaster over terra cotta, the interior finish being of red pine. Semi-indirect electric lighting is to be provided. The roof is of felt and gravel.

Arrangements have been made on the ground floor for a library and for administration offices, while on the other floors there will be the usual toilet accommodation. Each residence will have accommodation for 15 teachers. A large playground will be provided at the rear of the school.

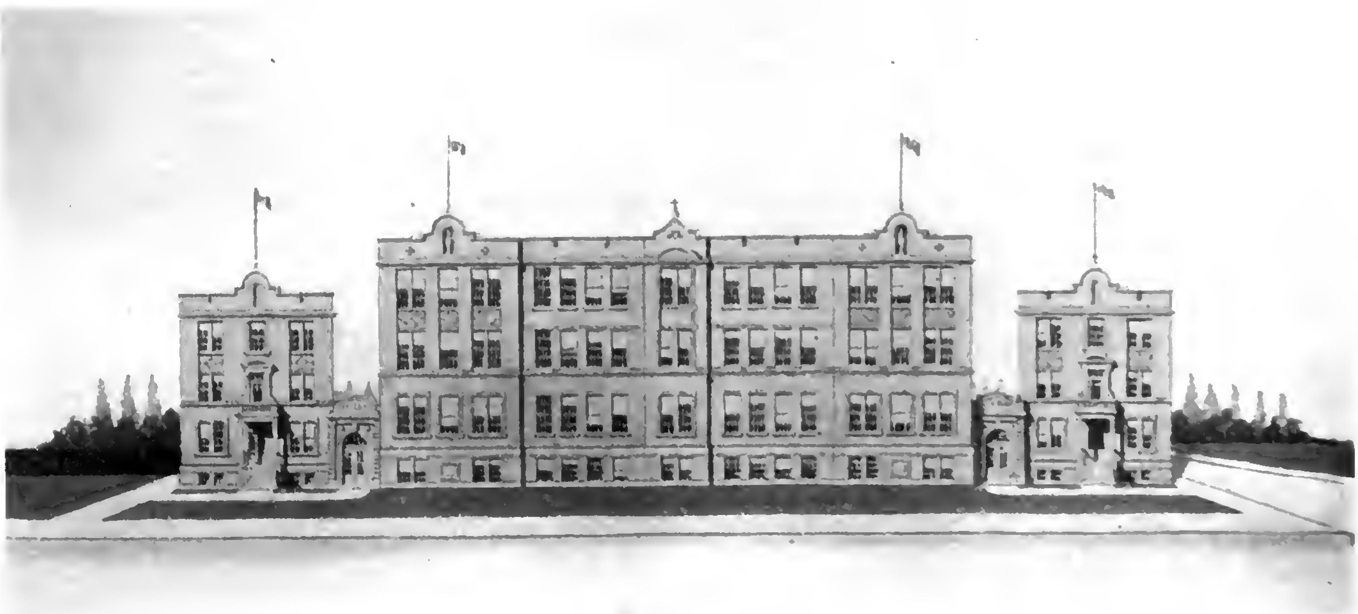
A recreation room and caretakers' quarters will be situated in the basement. In another portion of the basement, will be placed the equipment, including two boilers, for the steam heating, on the Dunham system; fans for the forced ventilation; and a vacuum system.

The following sub-contracts have been let: steel, Phoenix Bridge and Iron Works Ltd., Montreal; heating and ventilating, T. Lessard and Son, Ltd., Montreal; brick work, E. Rochefort, Montreal; cut stone, C. Piche, Montreal; plumbing, roofing and galvanized iron work, T. O'Connell, Montreal; tile and marble, Smith Marble and Construction Company Limited, Montreal; electric lighting, W. J. O'Leary and Co., Montreal.

Reinforced Concrete Failures

There seems to be a general impression that reinforcing rods stripped clean of concrete at a break in a reinforced-concrete failure are proof of green concrete. Investigators, in fact, are apt to take such a condition as primary evidence that the concrete had not set and to search for some cause that would explain such weakness. It is more than doubtful, however, that such an assumption is warranted.

The fact is that, under shock of collapse, steel tensile resistance or sufficient embedment will prove stronger than adhesion and that a firm, well-set concrete will strip clean from rods to which it has an adhesion far beyond that necessary for a proper transmission of normal stress.



Architect's Perspective, Roman Catholic School, Cote des Neiges.

Municipal "Clean-Up" Campaigns

Various Methods and Plans as Employed by U. S. Cities —Organization — Programmes — Benefits Derived (Conc.)

Sanitary Inspection

As a preliminary to the Clean-Up campaign in Kirkville, Mo., an inspection was made of all grocery stores, drug stores, bakeries, dairies, etc., by the State Pure Food Inspectors. The work continued over many months, and every Sunday one of the local newspapers devoted an entire page to the report of the conditions, good and bad. Each concern was scored on various points of sanitation on the basis of 100 per cent. perfect, and the Sunday paper printed the scores of all concerns inspected the previous week. Thus the interest of the public was roused to watch the scores. In the instances where the low scores were made the effects of public disapproval were instantly felt.

Flies and Mosquitoes

Swatting the fly plays an important part in the Clean-Up campaign of every community, and in nearly every city fly extermination literature is distributed during clean-up week. Bulletins, rubber stamps, fly traps, motion pictures, lectures, lantern slides, etc., everything available is used to depict the ravages of the fly. Fly extermination leaflets were sent to business establishments, to mothers' clubs, and post cards were sent to merchants whose places of business might be noticed to be fly infected. Boy Scouts distributed the literature and also reported as to stable conditions. Letters directed to business establishments, suggesting the use of fly swatters and traps as advertising material, were a further movement against the house fly. In Cincinnati a circular explaining the need of exterminating the winter fly was distributed through school children, and a marked reduction in the number of flies was secured. In 1915 a special general committee on fly extermination was named and became one of the most active factors in the campaign. Classes in manual training in the public schools made fly traps, the Public Library had prepared a complete set of lantern slides on fly extermination, and the committee had prepared and printed and distributed 50,000 circulars on the house fly and methods of extermination.

A rubber stamp with the inscription "Kill That Fly," together with the cut of a fly and a hand pointing in its direction was effectively used in the Cincinnati Clean-Up campaign. These stamps were so popular for use on correspondence and other literature that several lots were procured before the demand could be met.

The use of fly traps so effectively demonstrated, especially in the packing-house district and wholesale district during the 1915 campaign, that the purchase of a great many more and larger ones was urged for the 1916 campaign.

Ordinances

In some instances the Clean-Up movement has crystallized into an ordinance making it unlawful for any person to deposit on any lot or tract of land within the city limits, tin cans, waste paper, or rubbish of any kind.

In St. Paul the Health Department is empowered to clean up vacant lots when the owners fail to do so and assess the cost against the property.

Paterson, N. J., prohibits the dumping of refuse on vacant lots.

A Toledo ordinance prohibits the sweeping of sidewalks during the day, obstruction of sidewalks with tables and fruit stands, and the distribution of handbills.

The Los Angeles Weed Cleaning Ordinance calls for the removal of weeds from vacant lots in the spring and fall, and a request for a revolving fund of $15,388 has been made to the Council by the Board of Public Works. The ordinance provides that property owners must have removed from their vacant lots all weeds in the two weeks following the third Monday in April; otherwise the work will be done by the City and the cost charged to the property owner and collected along with the taxes. The ordinance also provides for a fall clean-up.

New York avoids a set time for Clean-Up by the provisions of its charter, which makes it the duty of the department to remove and dispose of light rubbish and refuse as often as the public health and the use of the streets require, and since this document was written public attention has been brought to the necessity for this work as fire prevention and thus has added to its importance. Because the materials are light and may be distributed over the streets the ordinance provides that all light refuse likely to be blown about the streets shall be properly wrapped, boxed or secured. Large cards such as are used for notifying express companies to call are placed in the windows and the rubbish cart calls at the door.

Waste a Source of Revenue

Tin cans and rubbish as a source of revenue must not be lost sight of. For instance, one city collected 37,000 tin cans which were deposited in the city dump. These cans might have been sold.

A Missouri city possessed but two miles of paved streets, which were a continual source of annoyance because they were not kept clean. The city possessed neither a sprinkler nor a cleaning system, and there was no money in the treasury for either. The women's clubs besought the merchants on these streets to turn over to them whatever funds they could spare to buy a sprinkler. This done, a second-hand sprinkler was bought. With extraordinary fore-sightedness the women noted the amount of dirt on the pavement, and so before turning the sprinkler on the streets sold $100 worth of the dirt and had the remainder carted to the low places that needed filling in in the cemetery. In this manner they utilized their foe for revenue.

Cost

The unit cost is almost impossible to obtain as most cities do not keep an accurate account of same.

Philadelphia removed 140,000 cubic yards of waste material at a net cost of 9 cents per cubic yard, and a gross cost—which includes every item of expense—slightly in excess of 12 cents per cubic yard, or 5 cents per family. One hundred and thirty-two dollars and forty-eight cents represents the unit cost per square mile for making 129 square miles of city area cleaner and brighter.

A tour through any city on the first day after

Clean-Up Week would convince the most incredulous that in promoting this movement the municipality had materially lessened the fire risk and made a marked improvement in sanitary conditions. Everywhere are heaps of waste materials and discarded articles, such as old bed springs, mattresses, sofas, glass, crockery, stoves, carpets, baby coaches, piled along the curb line.

The following are some of the results conceded worth while in most of the cities engaged in the movement:

A continuous campaign accomplishing permanent good.

Stimulation of business. (A canvass of the cities of the United States having clean-up campaigns resulted in the showing that 71 per cent. of the merchants were positive that their business had been increased.)

Improvement of housing conditions.

Distinct educational value for the young.

Prohibition of open garbage cans in some cities.

Sanitation in the handling of food products.

Better laws and methods in the disposal of garbage and rubbish.

Reduction in fire loss; thus reduction in insurance rates.

Elimination of unsightly lots and spots.

Hundreds of school gardens.

Renovation in most of the homes in a way they had never been renovated before.

A great reduction in the number of flies and mosquitoes.

A stimulation of civic pride and cleanliness and safety of the home.

A united effort by practically the entire population toward an end for the public good.

The education of school children toward a better idea of living conditions.

The razing of dangerous buildings.

Elimination of public dumps, prospective early elimination of many more.

Hundreds of new street litter cans.

Higher standards of the people for home and city.

Cleaner yards and vacant lots.

Distribution of thousands of fruit and shade trees.

Collection of combustible waste by Salvation Army, relieving Street Cleaning Department, and reducing dump evil.

Development of community spirit through united action in a movement for public welfare.

Safer, cleaner, healthier and more beautiful cities.

Recommendations for 1916

Special effort to devise some workable plan to attack successfully the problem of the vacant lot.

Special stress laid on the downtown section by organized effort of the residents and owners of downtown buildings.

Some organized effort to interest manufacturers.

Instruction of all inspectors.

Revision of city ordinances.

A "vigilance committee" made up of people with leisure time and who are willing to devote it to the campaign.

Uniform reports from schools.

Some methods to bring about better conditions on streets and alleys.

Greater effort toward securing the use of proper receptacles for garbage and rubbish, and the adequate removal of same.

Some plan for securing observance of the law for tenants as well as landlords of tenement houses.

The Schoop Metal Spray Process

Coating Surfaces of any Nature with any Metal, Demonstrated at University of Toronto. Paper read at McGill University

By T. Stanfield Worthington

A new process of coating objects of almost any nature, with any kind of metal, has recently been placed before the public in demonstration at McGill and Toronto Universities. The invention is not at all a new one, but is the culmination of years of research work by Dr. Max Ulrich Schoop, of France, an electro-chemist of international reputation. Solid particles of any metal are rendered molten, atomized, and projected on metal or other surfaces so that they form an amorphous part thereof rather than simply a thin covering which will wear off by abrasion, oxidation, or corrosion.

No surface of any nature whatever is too small nor too large to receive a coating of almost any metal, varying in thickness from 1/1000ths of an inch to as thick as may be desired.

As already stated, the process of spraying metal is not a new one; crude attempts had been made of applying metal to surfaces by pouring molten metal into a high-pressure jet of steam directed at the object. This process was very unreliable and inefficient, and was ultimately abandoned. Experiments with spraying hot metal, however, showed that adhered coatings were sometimes formed. These observations, together with those of the spreading and adhesive action of bullets fired at an iron plate, suggested a combined apparatus for pulverization and deposition which proved a vast improvement on previous processes. This apparatus is now in quite extensive use.

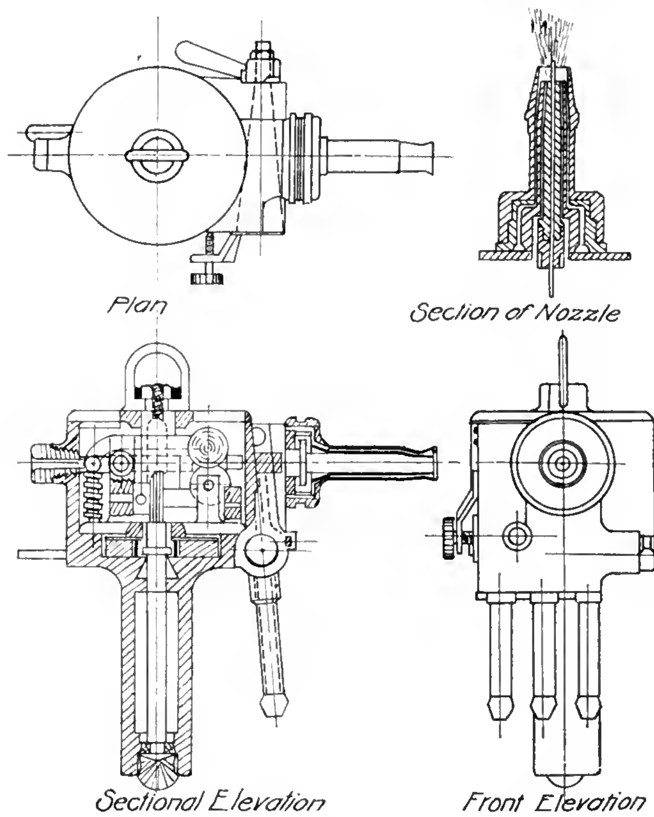
Apparatus

The essential parts of the machine, or "pistol," as it is called, are a combined melting and spraying jet, and a feed mechanism. The metal, in the form of rod or wire, is fed to the melting flame, which is formed by coal-gas, water-gas, acetylene, or hydrogen—burning in air or oxygen, according to the metal used. The gases are supplied at such pressures as to insure a highly de-oxidizing flame and yet prevent blowing out. The spraying jet is carbon dioxide, nitrogen, air, or steam, and is fed at such a pressure as to produce sufficient velocity for successful coating. The various pressures must be kept constant by accurate gauges and reducing valves. The feeding of the wire is accomplished by a small pneumatic motor, driven by the spraying medium, either in series or parallel with the main jet. The dimensions of the wire nozzle and feed mechanism vary with the different metals, and are so designed as to be readily interchangeable. For small work, hand operation is sufficient; but, when large work is undertaken, it is more convenient to have mechanical traverse and control.

To obtain the best adhesion, the surface on which the metal is sprayed must be thoroughly clean and of an open nature to give a key for the deposit. Sand blasting with sharp sand has been found best, shot giving too polished a surface. Such surfaces as fabrics, wood, unglazed earthenware, and asbestos require only freedom from grease, as their surfaces give a natural key. The mention of wood and fabrics as suitable substances to coat by means of an apparatus in which an intense flame is used may cause some surprise, which will be increased by the statement that celluloid, and even explosives, can be safely sprayed with metal.

Jet Design

With a given design of jet there is only a certain volume left by the air-jet which can be filled with flame, and this flame has a limiting temperature which



Plan, Elevation and Sections of "Pistol."

cannot be exceeded. The wire, passing through this cone of flame, is melted, partly by radiation, but chiefly by conduction. There is a definite limit to the amount of heat which can be picked up by the wire passing through the flame, and a definite limit to the rate at which it can be melted, which cannot be increased by forcing more gas into the flame, as the extra gas is merely blown away by the air-jet. It is possible to increase the rate of melting by shaping the nozzles so as to leave room for a larger cone of flame. There is, therefore, a definite and most economical quantity of gas which should be used in the pistol, this quantity being about 1.5 cubic foot of hydrogen per minute and 0.5 cubic foot of oxygen, or about 0.8 cubic foot of coal-gas to 0.65 cubic foot of oxygen for the present standard designs.

The outer jet performs a threefold purpose; it keeps the wire and nozzles cool, cools the object, and produces the requisite velocity. The velocity of the air leaving the jet will be independent of the volume discharged, and depends only upon the pressure at the jet, so long as there is no disturbance due to the entraining of air from the surrounding atmosphere. This, of course, will actually occur in practice, and the layer of air must have a certain thickness in order to prevent its being broken up and its velocity destroyed by mixing with the surrounding atmosphere. In addition to this the air-jet has to atomize the molten metal, and accelerate the particles up to its own velocity.

As at present constructed the standard pistol uses about 0.55 to 0.6 cu. ft. per minute for every pound per square inch of air pressure, so that with an air supply at 80 lbs. per sq. in., which is a very suitable figure for ordinary spraying, the air consumption will be from 45 to 50 cu. ft. per minute. The mass of this air will be from 830 to 920 grammes, and the mass of metal sprayed will amount to about 8 grammes in the case of iron to about 200 grammes in the case of lead.

Deposition

The action of deposition is probably a complex one. The minute particles of solid metal are driven with such force against the object that, in some cases, they fuse, but owing to their small relative size, are promptly chilled by the object to which they adhere. In addition, the suddenly chilled particles are possibly, or even probably, in the state of unstable equilibrium found in "Prince Rupert's Drops," and act like so many minute bombs, bursting on impact into almost molecular dimensions, and penetrating the smallest cracks and fissures of the object.

The process requires some care in manipulation, as, by varying the conditions it is possible to spray porous or non-porous coatings, and, with some metals, anything from a pure metal to a pure oxide. With care, however, non-porous, oxide-free, adhering coatings can be produced of almost any metal on almost any solid. In addition to metals, it is possible to spray fusible non-metals, or, by standard wires, alloys of metals, or mixture of metals, with non-metals.

Uses of Metal Spraying

The process is so new that its uses are still partly to be developed, but it is easy to see that it may have far-reaching value for protective coatings against weather or fire, for ornamental work, for electrical work, for the production of special alloys, for joint making, and for many other purposes.

Quite in a different category comes that of very fine casting. The surface of a pattern polished or slightly greasy is most minutely copied, and it is possible to produce process blocks very rapidly. It may also be useful to line molds before pouring in the metal.

The bulk of the work has hitherto been carried on in laboratories, but the apparatus is gradually becoming used in the more progressive factories where extended facilities, and the knowledge of specialized requirements, will insure rapid improvements in technique and results.

The Metal Coating Company of Canada, Montreal, holders of the Canadian patents on this process, gave an interesting demonstration of the process at the University of Toronto from April 10 to 15 inclusive. Many interesting specimens and samples of the process were on exhibit, and many practical operations were performed for the benefit of visiting business men.

Clay Qualities—Testing and Sampling

To Overcome Difficulties in Manufacture and Ascertain the Possibilities of a Profitable Business (Conc.)

By H. B. Henderson

The burning range temperature is most important. There are many clays and shales which will burn to a beautiful product at a certain temperature, but fail either above or below this temperature. A sample ware burned at this temperature might induce one to build a plant for the manufacture of the ware, but commercial operations would soon develop the fact that the material was impossible and the plant doomed to failure.

Limey clays often burn red at low temperatures, due to the iron content, but at higher temperatures when the lime begins to act, the iron is taken up with the lime to form a lime iron silicate, which has a buff green color.

A small amount of finely divided lime in a clay has no material effect, but as the lime increases in quantity it begins to get the limey color and short burning range effect noted in heat curves. Still higher quantities may act as a refractory and prevent the mass from fusing, but such very high limey clays will slake and crumble to pieces when exposed.

Gypsum (sulphate of lime) is frequently found in clays. It is the mineral which causes scumming, and any clay ware suitable for face building material should be tested for this trouble. Gypsum does not dissociate at low kiln temperatures and consequently may not act as a flux. When it develops as a white coating it goes through the fire unchanged, and the ware is unsightly in consequence. This is particularly true in oxidizing kiln conditions. Under reducing conditions, the sulphate breaks up and the lime content is set free to play the part of lime, and this may occur at a temperature when the ware may have nearly approached the failing point, and this additional flux introduced may be the last straw. When the surface is heavily coated with it, it may increase the density of the surface materially and cause increased shrinkage. If the ware has lamination the result would be to crack the surface and perhaps cause it to curl up and peel off.

Iron

Every clay contains iron in some form and in some degree, but any detailed discussion of iron in clay is far beyond the limits of this paper. Briefly, the iron may be present as a ferric (red) oxide, and it is to this that the red color is due; it may be ferrous oxide, or a carbonate, or a sulphide, or a constituent of some of the silicate minerals. It can be seen at a glance that its effect as a coloring agent will largely depend upon the state in which it occurs in the clay. As a red stain, coating each grain of clay, it would have the maximum coloring power. As mineral grains its coloring power depends upon the disassociation of the mineral at kiln temperatures and upon the fineness and distribution through the clay mass.

Usually, when in the form of a mineral other than the ferric oxide, a part or all of it passes into some other mineral form and it is lost as a red coloring agent. For instance, in the form of di sulphide (iron pyrites), when sulphur is driven off, the iron remains as ferrous oxide, in which form it is an active flux and readily takes up silica, lime, etc. If the kiln conditions are oxidizing, some of the ferrous oxide will be oxidized to the red oxide and serve to color the ware red, but a part, and the greater part, will be ferrous oxide which will combine with silica to form a black silicate. Such clays will first develop a red color from the free red oxide present, then become red-brown, the brown due to the effect of the black silicate, hence good color range may be very short and varying. As a red stain on the grains of clay, and without any appreciable amount of other iron minerals the red color may continue even until the ware is burned to glassiness. Iron carbonates will behave the same as the sulphides so far as color effect is concerned.

This again shows how futile chemical analyses are in determining the value of common clays, and also how important it is to determine the burning range which at the same time determines the color range. We may have beautiful ware at a certain temperature and there might be a safe burning range, but the color range may be very unsatisfactory.

Iron sulphide is frequently the cause of "popping." The little spot in the center of the "pop" will be red or black and will appear at a low red heat below cone 010 if due to iron minerals.

The danger from iron pyrites is dependent upon the quantity and state of aggregation. Thus, 5 per cent. of 20 to 40-mesh pyrites would not be noticeable in ordinary stiff mud products, while 5 per cent. of 16 to 20-mesh pyrites would cause some popping and where a grain happened to lie near the surface, a small fragment would fly off, destroying surface effect. If the quantity is large, as sometimes happens, the volume change of the pyrites may be great enough to burst the brick.

Iron, when in the form of pyrites, gives its greatest trouble in burning. The sulphur begins to come off at a low temperature, but it does not come off completely at any temperature, although the greater part of it can be roasted out before the clay becomes vitrified. Any sulphur given off after the mass becomes vitrified will cause blebs in the mass—bloated ware, familiar to nearly every clayworker. The swelling of ware in continuous kilns, which nearly every operator of a continuous kiln has experienced, is probably a sulphur trouble due to the sulphur gases of the kiln and not to the sulphur in the clay.

Magnesia is always present, usually in small amounts and gives no trouble. It may be in the form of a carbonate (dolomite and magnesite) or as a constituent of some silicate. Small amounts of magnesia are said to be beneficial as a flux, in that they produce toughness. In large amounts, we have found the material to have a short burning range similar to the behavior of lime. Magnesia, potash and soda in the form of sulphates cause efflorescence—the white scum which comes out on the wall after the brick are laid; indeed, it often appears on the ware in the piles on the yard.

Carbon

Carbon gives lots of trouble and if the clay is dark colored, the burning should be watched closely and a proper test should cover this feature. Carbon is a reducing agent, i. e., it takes oxygen from other minerals. Until the carbon is burned out oxidation of other minerals cannot take place and in their reduced condition they may be active fluxes. On the one hand, we have fluxes producing a vitrous impermeable body, and on the other hand, we have carbon and sulphur gases unable to escape as they develop, and instead, fill the mass with blebs which become larger and larger as the temperature advances.

Laboratories properly equipped have machines for the several processes which duplicate commercial conditions and are especially adapted to develop the difficulties in the clay. The laboratory machines are necessarily small and the results are largely dependent upon the experience of the operator and his knowledge of commercial operations. The tests, to be of value, must be practical, and a laboratory equipped with machinery for practical operations would require machines of all types and would be a greater institution than any factory, which is out of the question.

The point is this: Materials are sent in with the request that samples of sewer pipe, brick, stiff mud and dry pressed tile, hollow ware, etc., be submitted with the report. This is clearly beyond the province of a laboratory test. The laboratory test digs into the behavior of the clay in every stage of the manufacture and the tests are extreme in order to search out every weakness in the clay. All the products of the machines are subjected to subsequent tests which endeavor to destroy the product in order to determine the limits of the clay in every step of the manufacture.

Presentable ware is not practical in a laboratory test except the test be repeated under conditions in each stage which the real test has shown to be best. This subsequent work belongs to the manufacturer of equipment. The manufacturers of machinery are interested in the sale of such machinery and are prepared to make tests of clays in their machinery which will show how good a quality of ware can be produced. More should not be expected of them, and herein lies the cause of many failures. One cannot expect a manufacturer of equipment to go outside of his field to search out the faults of clay. He tests the clay honestly and sends back the results of the test, and is expected and expects, to give guarantees in regard to the working behavior. It is not his fault if the clay has had drying qualities, short burning range, scumming or efflorescence difficulties, bad color or lack of color range. Neither his machinery nor his test is at fault if the clay contains iron pyrites or concretionary iron or lime, if it develops cooling cracks or is seriously handicapped by porosity or lack of hardness range.

Cause of Failures

The manufacturer knows what his equipment will do with the material and there his responsibility should end. If failure follows, the fault largely lies with the owner of the material or the promoter of the project. The work of an occulist and optician are a parallel; the one tests your eyes, the other fits your glasses to them. If the eyes are normal, if they are not defective other than mere focal adjustment, the optician's work is satisfactory, otherwise not. In clayworking the time to settle such questions is before the plant is built, not afterward.

A recent test is illustrative. The material required an excessive amount of water to pug and it changed quickly from a mealy mass to one too soft to work. Unless tempered just right, there is danger of breaking the machine on one hand, or, on the other hand, ware too soft to handle. This fact, small as it seems, should be brought out and the factory equipped for a more uniform degree of pugging than is generally provided. Thousands of dollars may be lost in factory operations before this fault is determined and corrected.

In the laboratory tests it is often necessary to supplement the tests by chemical or mineralogical research. These are of little value alone, but are often of great value in determining the cause of failure.

Nearly every clayworker appreciates the troubles and loss in drying. One may build a dryer and if it fails, build another, and another, if his money holds out, until he has found a satisfactory one or proven that the clay cannot be profitably dried. Many have done this. We have seen clays possessing all the desirable machine qualities with none of the defects, yet they would persistently crack under all degrees of drying treatment that might be commercially practicable. The burning range was sufficient and the color good, but the clay was worthless because the market would not warrant the expensive treatment necessary to insure reasonably good ware.

Laboratories cannot be equipped with all types of dryers, but must be equipped to determine the drying qualities of a clay. Ohio probably has more good and fewer bad clays than any state in the Union. Of the sixty-eight known clays tested, only 15 per cent. were first class, namely: That could be safely dried in twenty-four hours or less; 51 per cent. were second class, requiring from thirty-six to seventy-two hours to dry safely; 19 per cent. required from seventy-two hours to one week to dry safely, and 15 per cent. required some preliminary treatment to make them practical. These dryers may be operated as sample dryers duplicating commercial dryers, or they may be adapted to special humidity conditions.

Shrinkage

Drying and burning shrinkages are obtained by marking the test bars with an instrument. The points are set accurately 100 mm. apart. When the ware is finished and set to dry, it is stamped very lightly, leaving a sharp yet distinct impression. At any stage of the test thereafter the distance between the point marks may be read directly in percentage on a millimeter scale. As a method adapted to all classes of clays we find it superior to anything yet proposed.

The burning requires a variety of kilns and must be under the direction of someone who has a knowledge of combustion and the effect of oxidation and reduction of pimpling, black coring, bloating and other burning difficulties. A description of these kilns is out of place here, but suffice it to say laboratory kilns are very inadequate for burning sample ware, but they have been designed and are operated to determine the difficulties in burning clay wares.

Following the burning comes the examination and testing of the ware, hardness and porosity, sometimes a freezing and thawing test is required to determine the value of the product. Color and color range must be considered and this involves getting a series of results at different temperatures. A clay may burn light red, dark red to brown within three cones. Another may be dark red through a range of five or six cones. If we select the dark red of the first to compare with a dark red of the second, it may have the better color, but because of the limited range of good color it is doubtful material for a profitable business.

Ordinarily we carry the burning through a range of fourteen cones, 07 to 7, which includes the average commercial kiln temperatures, not counting pottery or refractories. The greater number of red burning clays fail at or below cone 7. On the other hand, an occasional clay develops a good body below cone 07, as shown in curves No. 2 and No. 7.

Scumming

Scumming must be looked for and reported and tests must be made for efflorescence. Blistering and popping must be accounted for. Vitrification range is very important for an impervious ware and besides in paving materials the character of vitrification must be considered.

Attempts have been made to develop a satisfactory laboratory test for payers without success. Only a commercial test, followed by a rattler test, is conclusive. The ordinary preliminary tests, however, show the character and range of vitrification and serve to eliminate any clays which are not worth further testing.

Third Longest Steel Arch

The Needles bridge, across the Colorado River between Arizona and California, near Needles, Cal., which was dedicated on March 25, is the third longest steel-arch bridge span in the United States. Its 592-ft. arch is surpassed only by the 840-ft. Clifton arch at Niagara Falls and the 979½-ft. Hell Gate arch at New York City. This new highway bridge is the second highway crossing of the Colorado in the 1,000 miles from its mouth in the Gulf of California.

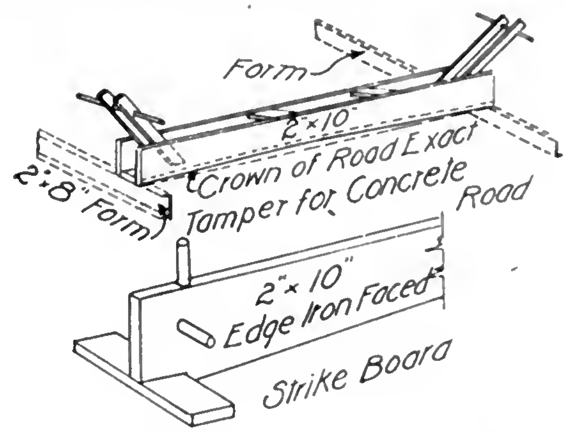
The Needles bridge is a three-hinged braced steel arch, 592 ft. centre to centre of end pins and with 100-ft. rise. The floor, a 22-ft. highway, is suspended from the arch ribs in the middle of the span and supported by posts at the ends. Approaches at each end, of 56 ft., make a total floor length of 832 ft. The end hinges are of the ordinary pin type, but the centre hinges are of the ball-and-socket type with a spherical compression bearing.

The method of erection was unique. The trusses from both the California and Arizona sides were built with the crown end resting on temporary pilework in the middle of the river and with the end hinges in place against the abutments. One truss was built so as to rest on the other. The tower for hoisting the trusses to make the centre-hinge connection was built from the material that was later used in the floor system. Sufficient end bracing was left from each truss to allow it to be hoisted into position without striking the tower, which was slightly narrower than the width of the trusses. The bridge was designed by J. A. Sourwine, County Surveyor, San Bernardino County, California. The steel was fabricated and erected by the Kansas City Bridge Company. J. P. Kemmerer was the construction engineer in charge of the work. The total cost of the bridge, exclusive of the concrete wing walls for the abutments, was $75,500. The Federal Government, the State of California and the State of Arizona each contributed $25,000, while the balance was furnished by the County of San Bernardino.—Eng. News.

A Combination Tamper and Strikeboard

For best results, concrete should be thoroughly tamped, and be as dense as possible. For sidewalk and road construction the practice generally followed is to place the concrete of such a consistency that it will not slide on a grade. While this is advantageous in so far as efficient handling is concerned, it is not conducive to best results in the matter of density. Especially is this true when the rapid commercial methods of striking off are used; the concrete is merely sheared off to the desired level, rather than tamped down. If a strikeboard which could be used as a tamper as well could be made, a firmer and more dense surface would result than one from the shearing action alone of the ordinary strikeboard. For this reason handles should be provided to the strikeboard, so that it can be worked up and down as it is drawn ahead. The following suggestion of such a combination is taken from a report of the Committee on Mixing and Placing Concrete as presented at the National Conference on Concrete Road Building, Chicago.

The construction of the tamper and strikeboard is very simple, as shown in Fig. 1, the strikeboard being crowned slightly in excess of the finished road requirement, while the tamper is finished to the exact cross-section of the finished road. After the concrete is struck off in the usual way for 10 or 15 ft., the center



being left slightly high, the tamper is used by two men, and moved forward a few inches at each application until the strikeboard is reached. In addition to giving the benefits of tamping for density, this brings the mortar to the face so that very little floating is necessary to secure a nicely finished road.

New Eight-room Public School for Cochrane, Ont.

(Continued from page 381)

The first floor plan is similar to the ground floor, except that a teachers' room takes the place of the principal's room, and the space over the entrance vestibule is reserved for a library. The staircases are at each end of the main corridor, and are built of oak.

The class-rooms are lighted with large mullioned windows from the left side only, with provision for electric lights. The walls have a 7-ft. dado of burlap, with a tinted sanded finish plaster above. The ceilings are stamped metal, and all the floors except the basement, which is concrete, are double, with insulating quilt and strips, the top or finish floors being hardwood. The ventilation is by heating ducts, which take off the foul air, fresh air being supplied through cased, indirect steam-heated radiators. Plumbing requirements are modern, and very complete.

The school was designed and its construction will be supervised by Angus & Angus, architects, North Bay and Sudbury, Ont.

Messrs. T. H. Higginson Limited, 70 Lombard St., Toronto, have just finished the sprinkler system in the South plant of the Goldie & McCulloch Co. Ltd., of Galt, Ont., within the time limit, and they have been awarded the contract to equip the North plant.

Montreal Builders' Exchange

Although the Montreal Builders' Exchange requested the Board of Control to revise the schedule of wages to be inserted in civic contracts, the scale as adopted shows little change. In two or three instances a slightly lower rate has been inserted, but in the main the schedule is from 5 to 15c an hour above that paid by the best city contractors. The following are the rates: Bricklayers, 55 cents per hour; carpenters and joiners, 45; cement finishers (foreman) 40; engineer on the crane, 35; electricians, 40; electricians' helpers, 27½; do. laborers, 22½; elevators: constructors, 35; iron workers: structural, 35; do. ornamental, 30; laborers, common, 25; do. on buildings, 25; lathers: metal, 40; do. wood, 35; masons, 50; marble cutters, 45; do. setters, 45; plasterers, 45; painters, 40; plumbers, 42½; do. helpers, 27½; do. steam fitters, 42½; do. steam fitter helpers, 25; stone cutters, 50; sheet and metal workers, 40; tile layers 45-50; carters: single wagon, $3.75 per day; do. double wagon, $6 per day.

For road work the rates are: for laying curbstones and flagstones, 35 to 45 cents per hour; for laying paving blocks, 48 cents an hour, and for asphalt, 40 cents an hour. Cement sidewalk finishers are to be paid 42 cents an hour. The wages of helpers are to be from 20 to 35 cents an hour.

Members of the Montreal Builders' Exchange on April 11 paid a visit to the Forests' Products Laboratories, University Street, Montreal. They inspected various departments, including those for the testing for strength of lumber and for the creosoting of lumber. The Laboratories have installed a small experimental plant for the latter purpose. Experiments are also constantly being carried on with a view of determining different uses to which Canadian woods can be applied, and of substituting native woods for purposes for which imported woods are now employed.

The Montreal Builders' Exchange have made a request to be represented on the Board of the Montreal Technical School. A deputation which waited on Sir Lomer Gouin, the Provincial Premier, received a very sympathetic hearing, the Premier promising to take the matter up with his colleagues. It was suggested by the deputation that representation of the Exchange on the school board would encourage young men to become more technically efficient in the building trades.

Increased Demand for Canadian Asbestos

Before the outbreak of the European war over 50 per cent. of Canada's asbestos was shipped to Germany and Austria, writes Consul Felix S. S. Johnson, from Kingston. When war broke out the two big asbestos corporations doing business in Canada found matters almost at a standstill. In a surprisingly short time they found a new and larger market for their entire output, with the result that the sales of the Asbestos Corporation of Canada increased 12½ per cent. over those of 1914, while the Black Lake Asbestos Co. turned a deficit of $32,000 in 1914 into a profit of $20,000. Prior to the war asbestos was used largely for industrial purposes, such as the making of shingles, fireproof boards, fireproof curtains for theatres, covering for machinery, etc. Today Canadian asbestos is finding a market in Great Britain, where it is being used as packing, for the covering of boilers and piping in the new ships built, and for other purposes.

Business Prospects Bright

Bird & Son, whose Roofing and Wall Board factory is located at Hamilton, report business prospects for 1916 as exceptionally good. Building operations and repairs, especially on the Western farms, have been more or less held up during the last two years, and now with money flowing more freely again, and prosperity returning, extensive repairs and new buildings are being pushed rapidly. Bird & Son are well posted as to actual conditions throughout the country, having branches in Vancouver, Calgary, Winnipeg, Montreal, Halifax, St. John, and Edmonton, from which their well known Neponset Paroid Roofing, Neponset Wall Board, and other products are distributed.

Preparing Harbor Plans

Mr. A. D. Swan, consulting engineer, of Montreal, is preparing plans for the mechanical equipment of harbors in Newfoundland, on the instructions of the Anglo-Newfoundland Development Company. The high freights now being charged by steamship owners have made it necessary to install machinery for the rapid handling of steamers. Canadian harbors are not, as a rule, provided with complete mechanical equipment, thereby making the charges of handling very high as compared with those prevailing in the United Kingdom.

Canadian Fairbanks Morse

Against a net loss of $101,099 in 1914, the accounts of the Canadian Fairbanks Morse Company for 1915 show a net profit of $709,048. The company's recovery was due to the demand for machines and equipment for munition factories and the enormous harvest in the West. Mr. H. J. Fuller, the president, states that the company's facilities are being at present taxed to the utmost, and prospects are good for the balance of the year.

Montreal Branch C.S.C.E.

The Rolling and Floating Steel Caissons of the Levis dry dock were described by Mr. L. R. Thomson at a meeting of the mechanical section of the Canadian Society of Civil Engineers, Montreal, on March 30. The dock, when finished, will accommodate the largest vessels afloat, and is being built for the Government by M. P. and J. T. Davis. The work on the caissons is sub-let to the Dominion Bridge Company, and is now in course of completion.

Correction

In the description of the Dale Presbyterian Church, Toronto, which appeared in last week's issue of the Contract Record, we inadvertently misspelled the name of the Eberhard-Wood Manufacturing Company, the contractors for the iron stairways.

A report from Quebec states that the Provincial Government has decided to construct an asphalt road between the city of Quebec and Valcartier camp. The greater part of the cost of $125,000 will be borne by the Provincial Government.

Cement Blocks vs. Bricks

Windsor, Ont., April 13th, 1916.

Editor Contract Record:

We were very much interested in a letter on the subject of "Cement Bricks" which appeared in the March 29th edition of your very excellent magazine and are taking the liberty of calling this gentleman's attention to certain facts relative to cement blocks, which he has apparently overlooked.

The cement block has certain advantages over brick and these points were described in the article written by W. W. Pearse, C.E., city architect for the city of Toronto. He states that, "cement blocks are here to stay as they appear to have certain advantages over solid brick. Being hollow, they are warmer and drier." He also says, "It is very generally accepted that a hollow cement brick wall is warmer in winter and cooler in summer than solid brick."

Yet this letter in your issue of March 29 tells us that, "they are neither as dry nor as warm as a brick wall—you cannot keep iron, steel, or leather goods in a cement building without keeping them well packed." This gentleman can tell you in a very few words why such is the case. We venture to say if he were asked his reply would be: "Because they are made from the dry-mix."

There you have the key to the situation. Make your blocks from the wet-mix or slush concrete and you at once eliminate all the objections mentioned by Mr. Thompson and retain the advantages over brick, described by Mr. Pearse.

Mr. Thompson has been in the business twenty-six years and apparently does not know that poured cement blocks are now being manufactured from the wet-mix concrete and that they are superior to brick. Clay brick will disintegrate in time; cement blocks, like wine, become better with age.

In Mr. Thompson's city, a certain machine company built an addition to their plant and used a poured cement block. All their valuable stock and tools are stored in this addition and the proprietors state that the place is perfectly dry and that there is absolutely no sign of moisture on the walls. These walls are neither lathed or plastered.

We will admit that Mr. Thompson is justified in his severe criticism of the cement block, when he refers to the dry-tamp product. However the wet-mix concrete is being substituted for the dry in practically all lines of cement work and in no product is this change more necessary or beneficial than in that of the cement block.

We trust Mr. Thompson will agree with our statement that a wet-mix cement block is cheaper, costs less to lay and is a better building material than solid brick.

Yours very truly,
Cast Stone Block & Machine Co., Ltd.
By F. J. Kinzinger, Secty.

Tenderer Deserves More Consideration

The Sherbrooke Board of Trade has passed a resolution asking the Federal Government to instruct the different departments to alter the present system of tendering so far as it relates to the retention of certified cheques—given as evidence of good faith—for certain percentages of contracts tendered on. The resolution points out that the cheques of the successful bidders are not only retained but are cashed and the proceeds held in the Government bank account until the respective contracts are completed to the satisfaction of the Government.

This procedure, it is contended, ties up unduly and unnecessarily for indefinite periods, capital and credit of the various contractors, needed in many cases to properly finance them through the very contracts they apply to—a particularly undesirable procedure in such a young country which needs every cent of capital and credit for expansion and development. While such procedure may not have a serious or detrimental effect in the case of large contractors who have immense capital, yet it undoubtedly and frequently deters and often debars contractors of merit, who have not sufficiently abundant capital or credit to allow a large amount of same to lie dormant, from tendering on public contracts, all to the detriment of the best interest of the public.

It is suggested that the Government should accept from successful tenderers guarantee bonds of approved Trust and Guarantee Companies, in lieu of accepted cheques, after the awarding of a contract, this method having been found satisfactory in many other cases.

The Montreal Builders' Exchange has endorsed the resolution and will ask other builders' exchanges to follow this example.

Manitoba Branch C.S.C.E.

At the last regular meeting of the Manitoba Branch of the Canadian Society of Civil Engineers, held at Winnipeg, Mr. Victor Gilbault delivered an interesting address upon the Panama-Pacific Exposition, which was illustrated with lantern slides supplied by Mr. M. C. Hendry. Mr. W. G. Chase, of Winnipeg, explained those slides pertaining to the waterpower developments throughout Canada.

The Department of Mines have issued bulletin No. 13, being a description of the laboratories of the Mines Branch of the Department of Mines, Ottawa.

Members of the Vancouver Branch C.S.C.E. on Active Service

Members—W. M. Davis, Colonel, 47th Battalion; J. R. Grant, Lieutenant, Royal Engineers; H. St. J. Montizambert, Lieutenant, 29th Battalion; J. H. Parks, J. M. Rolston, 29th Battalion.

Associate Members—H. L. Bodwell, Adjutant, 47th Battalion; J. F. Cahan, Lieutenant, 1st Canadian Pioneer Battalion; J. R. Cosgrove, Lieutenant, Div. Engr. 1st Canadian Contingent; J. A. Delancey, C. G. Du Cane, Major, Royal Engineers; M. L. Gordon, LeR. F. Grant, Adjutant, Can. Overseas Rly. Constn. Corps, c/o Office 1/c Records, London; N. M. Hall, 2nd Lieutenant, Royal Engineers; E. N. Harvie, 6th D.C.O.R., Vancouver; J. B. Holdcroft, Sergeant, 6th Field Co. Div. Engineers; R. G. E. Leckie, Colonel, 16th Battn., 1st Contingent; Campbell Macdonald, Lieutenant, Eng. Corps, 1st Contingent; Thos. Murhead, Lieutenant, 30th Battalion, 2nd Contingent, K. M. Perry, 1st Contingent.

Juniors—A. W. McKnight, Lieutenant, Div. Engrs. 1st Contingent; W. S. Ford, Private, Can. O'seas R'ly Constn. Corps.

Students—J. Hammer-Schou, 2nd Contingent; A. E. Humphrey, Captain, 2nd Contingent; J. C. Glanville, 1st Contingent.

Roll of Honor—D. P. Bell-Irving, Lieutenant, Divl. Engrs. 1st Can. Contingent.

Personal

Mr. Angus Matheson, a brick mason of Fort Frances, Ont., has enlisted for overseas service with the 141st Battalion.

Mr. Hugh Walker, a well-known contractor of Algonquin, Ont., has just returned from a four months' visit to England and France.

Mr. J. Martin Sterling was the guest of honor at a banquet given by local engineers in the Vancouver Hotel, Vancouver, B. C., on the 8th inst.

Mr. R. S. Lea, Montreal, has been in attendance at the session of the International Waterways Commission, Washington. Mr. Lee reported to the Commission on the level of the Lake of the Woods, Manitoba.

Mr. E. D. W. Courtice, Assistant Superintendent of the John Street Pumping Station, City of Toronto, has resigned his position to enter the employ of the Hare Engineering Company Limited, as Assistant Engineer.

Mr. N. K. Hay, who has been city engineer of Sydney, N. S., for the last three years, has resigned his position to enlist in the 224th (Forestry) Battalion. He has been granted leave of absence while at the front.

Mr. John D. McBeath, a well-known civil engineer of Moncton, N.B., has been given a commission with the Canadian Engineers for overseas service, and will leave shortly for Ottawa, where he will take the necessary course. Mr. McBeath is a graduate of the University of New Brunswick, and was for a time assistant engineer in Moncton, and later assistant engineer in Medicine Hat.

Lieut.-Col. J. A. Hesketh, recently connected with the engineering staff of the C. P. R., has been promoted from Major to Officer Commanding the Lord Strathcona Horse, with the rank of Lieutenant-Colonel. Lieut.-Col. Hesketh is well known in Winnipeg, where he resided for a number of years, and also throughout the West. He is a graduate of the Royal Military College, Kingston, and served in the North-West Rebellion. He was director of bridge work for the C. P. R. throughout the West, and is a member of the Canadian Society of Civil Engineers.

Obituary

Mr. Frank Anthony, a retired painting and decorating contractor of Brampton, Ont., was accidentally killed on April 8 by falling from the railway bridge near Brampton station to the street below.

The death occurred, on April 9, of Mr. David A. McIlroy, a prominent manufacturer of Hamilton, Ont. Mr. McIlroy, who was born in Hamilton thirty-seven years ago, commenced his business career as a junior in the office of Hendrie & Co., of Hamilton. Later he transferred to the office of the Hamilton Bridge Works Company, in which he rose rapidly to a position of trust, which he held for many years, until failing health compelled his resignation five years ago. After spending a year travelling in the south, he returned, with health improved, to Hamilton, and started the Hamilton Steel Construction Company. The news of his death came as a shock to his friends, as his condition was not considered serious until a few days before he died.

The Hare Engineering Company Limited, have recently received a contract to install their Fulton Water-cooled Mechanical Stokers in the new plant being built by the York Knitting Mills Ltd., Toronto.

If, as anticipated, the C. N. R. goes to Medicine Hat, Alta., this year, it is announced that the Saskatchewan Bridge and Iron Works will complete and operate their plant there, employing some 200 men.

Mainly Constructional

East and West—From Coast to Coast

The Iron Works, Limited, Owen Sound, Ont., have obtained a charter.

The Cement Company of Port Colborne, Ont., have resumed operations.

The city of Ottawa has seventy-two applications for the office of Works Commissioner.

The International Engineering Company, of Montreal, report a profit of $77,778 for the year 1915.

The building permits issued by the city of Hamilton this year to date represent an expenditure of $159,315.

The style of the Berlin Machine Works, Limited, Hamilton, Ont., has been changed to P. B. Yates Machine Co., Ltd.

The name of the Chateauvert Quarry Company, Limited, has been changed to that of Deschambault Quarry Corporation.

The City Council of Toronto has made an additional grant of $100,000 towards the cost of the Toronto-Hamilton Highway.

It is rumored that the Canada Cement Company have an order for one million barrels of cement from the French Government.

The Canadian Steel Specialty Company, Limited, has been organized, with head office at Grimsby, Ont., and a capital of $100,000.

The Builders' Exchange of Saskatoon, Sask., at a recent meeting, passed a resolution favoring the erection of an incinerator in that city.

Messrs. Wm. Steele & Sons Co., Philadelphia, Pa., Architects & Engineers, have opened an office at Room No. 423 Ryrie Bldg., Toronto.

There are signs of a marked improvement in the building trades in Toronto. On the 6th inst. the city issued building permits representing an outlay of $21,700.

Messrs. R. S. and W. S. Lea, of Montreal, will report on improvements to the water power at the paper mills at Pont Rouge, P. Q., of F. W. Bird and Son, East Walpole, Mass.

Fowler Machine Works, Limited, is the name of a recently incorporated company with head office in Vancouver and capital of $10,000, to carry on the business of iron-founders, mechanical and electrical engineers, brassfounders, boiler-makers, etc.

The building permits issued by the city of Ottawa during January, February, and March, 1916, totalled $156,900—an increase over the same period of last year of $28,475. Ottawa contractors complain of the indisposition of the loan companies to advance money for large buildings at the present time.

A commission of water experts, consisting of Messrs. R. S. and W. S. Lea, Montreal; F. W. Thorold and Co., Toronto; and Mr. F. A. Dallyn, sanitary engineer of the Ontario Provincial Board of Health, will report on the water supply for the city of Sarnia, Ont. The object is to obtain a better and larger supply of water.

The Builders' Exchange of the City of Stratford and County of Perth, Ont., held their annual meeting on April 6, marking the close of a very successful year, during which the membership had almost doubled. Mr. George Pounder was elected president. After the business of the evening had been disposed of the members held their annual banquet at the Royal Cafe.

Tenders and For Sale Department

To Contractors

Sealed tenders will be received up till noon, **April 26th, 1916**, by the Secretary, for the erection and completion of a six-roomed Public School Building for Finch School Board Section No. 3, in the Village of Finch, Ont.

Drawings and specifications can be seen at the undersigned. The Board reserves the right to reject any or all tenders. The successful tenderer will be required to furnish satisfactory guarantee as to good faith. Tenders will be opened after 8.30 o'clock p.m. May 1st.

GEO. S. CASSELMAN,
Secretary.

16-17

Tenders for Bridge

Tenders will be received and contracts awarded by the Council of the Township of Blandford at the Commercial Hotel, Woodstock, on **Saturday, the 29th day of April**, at the hour of 2 p.m., for the construction of a 40-foot steel girder span with concrete floor and abutments, at Ratho. Tenders may be separate or in bulk, and may be addressed care of:

F. J. URE, C.E., Woodstock, Ont.
GEORGE OLIVER, Twp Clerk, Bright.
EDWARD ADAMS, Reeve, Woodstock.

16-16

Sealed tenders addressed to the undersigned, and endorsed "Tender for metallic fittings for New Customs Offices and Examining Warehouse, Sussex Street, Ottawa," will be received until 4 p.m., on **Thursday, April 27, 1916**, for the work mentioned.

Plans, specification and forms of contract can be seen and forms of tender obtained on application to the office of Edwin Francis, Caretaker, Post Office, London, Ont., R. L. Deschamps, Overseer of Dominion Buildings, Post Office, Montreal, Thos. A. Hastings, Clerk of Works, Postal Station "F," Toronto, and at this Department.

Firms or others tendering are hereby advised that two separate tenders are to be submitted; one to cover filing cases, etc., the other to cover shelvings, etc.

Persons tendering are notified that tenders will not be considered unless made on the forms supplied, and signed with their actual signatures, stating their occupation and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honorable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, April 13, 1916.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—148.

The City Council have let the following contracts for supplies:—castings, Galt Foundry Company, Stone Road; hardware, Buchanan & Tait, Main Street; cement, I. D. Burns, Main Street, and Scott & Hogg, Water Street S.; lumber, W. I. Reid Company, Water Street N.

London, Ont.
The London Concrete Machinery Company, Ltd., have awarded contracts for the supply of machinery to the following firms:—Sparks & McKay, Hamilton; William Fralick, Wellandport; Globe Graphite Mining & Refining Company, Port Elmsley; J. C. Hunt, Dorchester; Dominion Steel Metal Company, Hamilton; Corporation of Village of Ormstown, Que.; George Bannister, Ottawa; J. E. Tomlinson, Malton.

Quebec, Que.
The City Council have let the following contracts for supplies:—pig lead and lead pipe, Charles A. Parent, 106 St. Joseph Street; cast iron pipe, Canada Foundry Company, 162 St. Antoine St., Montreal; iron and brass castings, F. X. Drolet, 206 De Pont Street, and Terreau & Racine, 196 St. Paul Street; brick, W. Cantin, Les Saules Street; clay pipe, Standard Clay Products Company, St James Street, St. John's, Que.

Fires

Ange-Gardien, Que.
Stable and barn owned by Joseph Letarte. Loss, $3,000. Will rebuild.

Aylmer, Que.
Residence of Herbert Routliff. Loss, $5,000. May rebuild.

Brooke Township, Ont.
Barns owned by Robert Toohill, Napier. Will be replaced by fireproof structures.

Chateau-Richer, Que.
Sawmill owned by J. Cauchon. Loss, $7,000. Will rebuild.

Drumheller, Alta.
Business block owned by W. E. McDonald. Loss, about $10,000.

Highfield, N. B.
Store and residence of Tobias Brothers. Loss, about $5,000.

Killarney, Man.
Plant of the Crescent Creamery Company, Ltd., Sherburn Street, Winnipeg. Loss, $5,000.

Lion's Head, Ont.
Store of Tackaberry & Tackaberry. Loss, $15,000. Owners considering rebuilding.

Napinka, Man.
Warehouses owned by James Carnduff. Loss, $6,000. Will rebuild.

Ottawa, Ont.
Residence of L. Charbonneau, Holland Avenue. Loss, $3,000.

Russell, Man.
Premises of the Union Bank of Canada. Loss, about $15,000. Manager, W. W. Barry.

St. Adalbert, Que.
Sawmill owned by Albert Caron. Loss, $4,000.

Ste. Foye, Que.
Residence owned by Ernest Myrand, 144 Latourelle Street, Quebec. Loss $4,000. May rebuild.

St. Hyacinthe, Que.
Hotel, owned by P. Jubinville. Loss, about $8,000. Will rebuild.

St. John, N. B.
Business block owned by the McLean Estate. Loss, $5,000.

Moulding shop of McLean, Holt & Company, Ltd. Loss, about $4,000. Manager, D. J. Barratt.

St. Lazare, Que.
Store and residence of Oscar Lavigne. Loss, $15,000. Will rebuild.

St. Paul du Buton, Que.
Sawmill owned by A. Blais and F. Letourneau.

St. Thomas, Ont.
Residence owned by Duncan Wrightman, c|o Pere Marquette Railway. Loss,

Business block owned by E. Morrissette. Loss, about $30,000.

Late News Items

Berlin, Ont.
The contract for laying about 6,000 square yards of concrete pavement with curbs and gutter has been awarded by the City Council to Ernest J. Holland, Ingersoll, at $8,742.

Brantford, Ont.
Tenders on the erection of a residence for E. L. Gould, 103 Darling Street, will be received until noon, April 22nd, by the Architects, Barber & Tilley, Temple Building. Approximate cost, $8,000.

Brockville, Ont.
The General Hospital Board have let the contract for masonry, carpentry and steel work required in the erection of a Home to A. Cameron, Alexandria. Approximate cost of building, $77,000.

Cottam, Ont.
The Secretary to the Gosfield Township Council, W. H. Noble, Cottam, will receive tenders until April 29th, for (1) drilling an artesian well and supply of castings, ets., and (2) drilling only.

Dartmouth, N.S.
The general contract for the erection of a foundry for the Williston Steel Foundry Company has been awarded to Rhodes, Curry & Company, Limited, Kempt Road, Halifax. Approximate cost, $16,000.

Halifax, N.S.
The following are contractors for the apartments now being built for F. A. Shaw, 32 Blower Street:—general contract, masonry, carpentry and roofing, J. D. Lavers, 1 Argyle Street; heating, Andrews Heating Company, Minneapolis; plumbing, C. H. Cragg, Water St.; electrical work, J. Starr Son & Company, Granville Street. Approximate cost, $10,000.

Montreal, Que.
The Protestant Board of School Commissioners, Belmont Street, have awarded the general contract for the erection of a school on De Jumonville Street to the Raymond Construction Company, Limited, 145 St. James Street. Approximate cost, $6,700.

Quebec, Que.
W. Brochu, 87 Claire Fontaine Street, has commenced the erection of a residence on Aberdeen Street, estimated to cost $7,000. Brick and frame construction.

Work has been started on a building for the Y. W. C. A., 125 Ste. Anne Street. The contract for excavation has been let to the Sharp Construction Company, 109 Fleurie Street. Tenders will be called shortly for the erection of the building. Estimated cost, $50,000.

St. Christophe Pont Viau, Que.
Vautrin & Bernier, 281 St. Andre St., Montreal, will receive tenders until April 28th for the erection of a chapel and parsonage.

St. Maurice de Thetford, Que.
The contract for interior alterations to the Roman Catholic Church has been awarded to J. St. Hilaire, St. Romuald, Que., at $35,000.

Toronto, Ont.
The plans for the proposed Masonic Temple on Spadina Road have been revised, and the cost reduced to about $175,000. The Directors expect to call for tenders shortly. Architect, H. B. Knowles, 1170 Broadway, New York City.

Wood Coffer Against Back of Dam Used in Replacing Masonry

Two temporary spillways left in constructing the La Boquilla dam of the Northern Mexican Power Company, Limited, were closed under a considerable head of water by constructing timber shutters across the upstream openings, building a rubble masonry wall across them and filling the space between wall and shutter with concrete in which large stones were bedded. The masonry placed in this space was laid under water, as the shutters could not well be made tight. The east spillway was deeper than the west, and the masonry proved so porus that it was not practicable to grout it. G. G. Underhill, chief engineer, and Edwin Duryea, Jr., consulting engineer for the power company, then decided to replace the back face of this masonry, doing the work in a timber cofferdam seated against the back of the dam. The method is described by them in a recent issue of the Cornell Civil Engineer.

The construction of the dam, which is in the State of Chilhuahua, Mexico, had been delayed by the difficulty of securing cement. Meanwhile the reservoir filled so that at the time the 33-foot-wide east spillway was closed it was passing water at a depth of 20 feet. The volume of water descending into the gorge below at high velocity menaced the foundations of the power house, 140 feet below the spillway floor. By the time it was decided to remove the porous masonry from the back of this spillway section cement had been secured, the dam had been carried considerably higher, and the reservoir had filled to about 33 feet above the bottom of the section to be repaired.

A cofferdam 46 feet high and braced with horizontal I-beam stringers inside vertical studding was used. Over the latter were nailed two layers of 2-inch plank covered with canvas. Because there was no site convenient for a launchway, the studding, floor and lower part of the sheeting were assembled on shore and handled to place by the two cableways spanning the dam. The cofferdam was completed in place and lowered a few feet at a time as it was built up. On reaching the required depth, the sides and floor of the cofferdam were caulked against the back face of the dam with bags, etc., by a diver. Several vertical cross walls of three 2 x 12 inch 40-foot timbers each were then set and wedged against the I-beams by the diver. These were found far easier to place than crossbraces, and were considered much superior. During the building of the cofferdam it was hung on two 1-inch wire ropes fastened to the floor near the upstream edge and clamped off around blocks hung from eyebolts in the masonry above. These lines pulled the bottom of the cofferdam against the masonry, while the top was held in by short side lines fastened to eyebolts on either side of the section. The lowering was done by two stiffleg derricks, set one on each side of the old spillway, helped when necessary by the cableways. The floor of the cofferdam was weighted with stone to help sink it.

When the cofferdam was in place and braced it was unwatered with three 8-inch centrifugal pumps. As the water was lowered, inclined timber struts were placed from notches in the masonry to blocks bolted to the studs. They were required in addition to the friction of the cofferdam against the masonry to overcome the uplift.

The coffer once pumped out, the work of removing the defective masonry to an average depth of a yard and replacing it with good concrete was readily accomplished, working from the bottom up. This wall provided a solid backing, enabling the interior part of the porous section of concrete to be grouted without difficulty.

Good Roads in Peace and War

THAT good roads are an indispensable asset to any country is being fully demonstrated by the present European war. Engineers generally have recognized that good roads are a military asset, but few have fully realized the momentous part being played by good roads in the outcome of the present war. They were probably the determining factor in stopping the great German drive early in the war on Paris. General Joffre, by the aid of motor transports, taking advantage of the splendid highway system around Paris, concentrated forces at strategic points with such rapidity that he was able to check the German drive and prevent the investment of Paris by the Teutonic invaders. By commandeering all available motors he was able to transport during the days previous to the battle of the Marne a steady stream of soldiers night and day, which was effective in turning the tide of invasion.

* * *

Again, the Kaiser's stupendous drive on Verdun, when that strategist launched his human battering ram against the great French fortress, was apparently defeated by the mobilization of sufficient French troops and munitions by vehicular traffic over well-maintained highways with sufficient rapidity to withstand the fiercest onslaught in the history of human warfare.

Add to these the conditions necessary to bear the heavy traffic transporting modern artillery, ammunition columns and the great number of fast-moving motor transport trucks, the strain of which may be partly realized when one remembers the millions of men to be fed daily with both food and shells. The nature of the surface required to withstand such traffic indeed must be of a most permanent nature. This volume and weight of traffic is such as to justify and require only the most substantial of roads, surfaces permanent enough to bear the shearing action of these heavily-laden, fast-moving trucks. Traffic must move quickly; the ever-present watchful eye of the enemy, the air-craft, are always ready to detect any traffic on highways and the slow-moving, mule-drawn transport which had its place in the South African campaign would only furnish good bomb practice in the present conflict.

The same argument, though in a less degree, proves the superiority of motor transport over steam roads. The steam line, being fixed in position, is a much easier target for air-craft and a tie-up must cause much greater and more prolonged delay.

* * *

Indeed, the present conflict appears to bring home to us sharply the strategic value of good military roads which appear to outweigh that of railways from a military point of view. Railways are much more easily demolished, harder to repair, and not nearly so flexible, especially in a rough country. Added to this there are generally many parallel roads, leading to the same destination, any one of which could be utilized in case another is destroyed. In modern warfare, where two large, well-equipped armies, of practically equal strength, battle, success is generally going to come only by applying at the crucial moment a strong, well-mobilized force at the weakest point in the enemy's lines. To do this, mobility and rapidity of movement in all directions is the essential feature, and here the great tactical value of the improved highway in lessening the fatigue of forced marches and increasing the effective radius of action, is appreciated.

Considering, then, how good roads conduce to the wealth of a country in peace times, as well as to the national defence in war time, the plea for more improved highways seems amply justified.

Architects' Association Has Not Exclusive Rights

An important decision respecting the Association of Architects of the Province of Quebec has just been handed down in the Court of Review by Acting Chief Justice Archibald and Justices McDougall and Mercier.

It appears that a Mr. Gariepy had transgressed the rules of the Association of Architects of the Province of Quebec by giving himself the title of architect without first becoming a member of the association. The association took the matter up, and the Supreme Court some time ago confirmed a ruling of the association which condemned Mr. Gariepy to pay a fine of $100. The Court of Review now reverses the judgment of the Supreme Court, and in so doing denies the Association of Architects of the Province of Quebec the right to exclude architects who are not members of their association from practising in Quebec.

The following extract from the recent judgment indicates clearly the attitude of the Court of Review on this question:—

"To justify plaintiff's conclusions we would have to rely upon inference and implication to agree to the proposition that the provincial architects' association is a close corporation—that the charter under which this action is brought gives the Association of Architects the exclusive right for their members to practise as architects in this province and to bar out all others who do not join their ranks. We cannot subscribe to such doctrine.

"The privileges afforded the association are stated in the terms of the statute—neither more nor less. By inference, we are now asked to decide that because the Bar, the physicians, notaries, surveyors and certain other professions have obtained exclusive charters wherein the prohibitive enactment is expressed in clear and unmistakable terms, the Legislature intended to do the same thing for the profession of architects, although the language used in the Architects' Act presents serious points of difference from the simple, direct and plain phraseology of these other acts.

"If such was the intention, why not express it? The fact that it was not so expressed is apt to lead one to the presumption that the law-giver did not intend to grant exclusive rights here. Coupled with the further circumstance that the architects when applying for and obtaining their charter, as well as the legislators upon granting it, had before their eyes and in their minds the charters already granted to the said other corporate entities, what conclusion are we to draw when we see them departing from well-known, symmetrically-drafted, bomb-proof models, to ask for and receive a version so at variance therefrom?"

The Sanitary Service at the Front

Writing in the London Times on the R.A.M.C. service in Flanders, Dr. Grenfell, of Labrador, who has been working with a Canadian unit, says:—

"The sanitary services of all the towns and villages near the line have been taken over entirely by the R. A. M. C. Sewers and drains have been put in order; garbage and filth disposed of at the least possible cost. At certain places near the line one sees a series of furnaces all made from old tins filled with clay, having air spaces between, which once lighted require next to no attention, but are eternally doing their work, like modern 'Valleys of Hinnom.' Water supplies are all the while being tested and retested by ambulatory laboratories. One sees everywhere the trail of their work in labels hanging to melancholy looking taps, such as 'This water is not to be used until chlorinated.' It is at best a muddy fluid that serves for trench tea. Yet at the front there is is less typhoid than measles.

"The happiest men we saw in France were in the baths close behind the trenches. In one converted dyeing factory 2,000 men got baths in a day. One saw batches of men rolling about in the huge vats filled with clean hot water, while their uniforms in superheated steam chests and under heavy hot irons were being freed from the plague of trench vermin, and entirely new sets of well-aired underclothing were being put out for each man. The splendid physique of the men, as one viewed these regiments in statu naturae before they returned once more to the battle line, suggested the pathos of the preparations of the Spartans before their 'field of honour' at Thermopylae. Yet to be of service these prophylactic measures have to be conducted so close to the firing line that just before we entered 'the baths' a stray 'Jack Johnson' lopped over fussily past the side entrance into the canal that furnishes its water supply. The lot of a washerwoman is not looked upon as heroic in civil life, but anyone inspecting the conditions under which the laundries close behind the lines carry on their warfare, with the essential coverings of a trench army, would find no reason to grumble if an occasional decoration fell into the hands of some of the leaders of these tireless hosts."

Ottawa Branch C.S.C.E.

At the meeting of the Canadian Society of Civil Engineers, Montreal, on the 13th inst., Mr. John Murphy, chairman of the Ottawa branch of the Society, gave an informal talk on a visit to the Panama Canal. By means of slides, Mr. Murphy described in particular the earth slides in the Calebra cut, referring to the manner in which the earth was forced up from the bottom of the canal, the means taken to remove the enormous masses which obstructed the waterway, and the difficulties which were encountered by the engineers. Afterwards Lieut. Col. F. A. Snyder, a member of the society, gave an address on map making and map-reading in military work. He described an original diagram for making military scales for interpolation of contours and the reduction and enlargement of maps, a method which has been adopted by the Canadian Militia Department.

Proceeding with Construction Work

The Montreal Board of Control has decided to proceed with the completion of the north wall and the construction of the south wall in connection with the aqueduct scheme and the new filtration plant. Plans are also being prepared for the new power house required for the proposed hydro-electric development portion of the scheme, by which power will be provided for pumping and lighting purposes.

Collingwood Adding Waterworks Equipment

The Board of Water Commissioners of the town of Collingwood have awarded the Turbine Equipment Company, Toronto, a contract to supply and install two De Laval single stage centrifugal pumps, each having a capacity of 1,000 Imperial gallons a minute, against 165 feet head, and each direct-connected to a 75 h.p. Canadian Crocker-Wheeler motor, complete with valves, piping and Venturi meter.

Work on the nave of the Episcopal Cathedral of St. John the Divine, in New York City, which will be the largest church in the United States, will begin May 8. The work is expected to take 5 years and to cost nearly $3,000,000.

The 10th report of the Board of Railway Commissioners for Canada, covering the year ending March 31, 1915, is just to hand.

Shall I Build Now, or Wait? Comparative Prices To-day and at Outbreak of War

(Continued from April 19)

Stone and sand—Prices somewhat easier.
Brick—Fully twenty-five per cent. drop.
Cement—Reduction of 10 to 15 cents a barrel.
Lime—Exactly same.
Lumber and millwork—Same, or slightly in advance of 1914; considerably lower than 1912-13.
Hardwall plaster—No advance.
Plumbing and heating—A considerable advance in nearly all metal prices.

This sums up the situation so far as we have been able to gauge price conditions in our last three issues. A number of miscellaneous items remain which are of more or less importance, such as paints, glass, roofing, etc. Discussion on these follow:

Fireproof Doors, Windows, Sash, Etc.

The A. B. Ormsby Company, Toronto, have supplied us with the following data regarding prices of metal doors and windows:

"In connection with hollow metal sash the price of iron has been steadily advancing and today we are paying about $3.00 more per cwt. for it than we were when the war broke out.

"In connection with steel sash—Any manufacturer that has not a heavy stock on hand at the present time will find it impossible to get section, as the Steel Trust are so busy they do not know what to do. The price on this has also been steadily advancing.

"Regarding fireproof doors, tin plate has gone up in sympathy with the other metals, and on account of the scarcity of lumbermen the price of timber has gone up, so that there is a considerable increase in the price of fireproof doors.

"Labor is getting scarcer every day and the quality poorer, the result being that it costs considerably more to make up the goods today than it did at the beginning of the war or a year ago."

Papers and Felts

The enemy found us unprepared in more ways than one. We had been satisfied to purchase a number of items of commerce from Germany because the cheap labor conditions of that country prevented our competing with them in cost of manufacture. Such items, for example, were bleaching and dyeing materials. The increase in cost of the analine dye, which has made itself so indispensable during the past ten years, figures out at more than 10,000 per cent. Bleaching materials have advanced about 1,000 per cent. Fortunately these items do not bulk large in the building trade, but manufacturers of ready roofing, wallboard, felt, etc., used in building have advanced their prices sharply and are taking orders for immediate shipment only. The following figures covering ingredients which enter into the manufacture of these articles show clearly the reason of the advance in price (Table I.) For these figures we are indebted to Messrs. Bird & Son, Hamilton, Ont.

Table I.

		Before the War	Mar. 1, 1916
Roofing rags	per cwt.	.85	$3.12
Alum	per cwt.	.95	4.75
Bleach	per cwt.	1.30	12.00
Soda ash	per cwt.	.65	4.00
Starch	per cwt.	1.79	2.05
New colored cuttings	per cwt.	1.40	3.50
New dark cuttings	per cwt.	1.00	3.00
Flax waste	per cwt	1.60	5.00
Sulphate pulp	per cwt.	1.75	3.05
Sulphite pulp	per cwt.	1.60	3.00
Bleached sulphite pulp	per cwt.	2.60	4.50
Mixed papers	per ton	5.00	10.00
Folded news	per ton	6.00	12.00
Kraft papers	per cwt.	1.00	2.30
Analine dyes	per lb.	.27	30.00

Metallic Roofing

Prices of most lines have advanced from 10 to 25 per cent., metallic ceiling material alone remaining at the old figure. The following table (Table II.) shows the relative cost of materials to-day as compared with August 4, 1914. These figures were kindly furnished by the Metallic Roofing Company of Canada, Toronto, who state that unless steel and spelter show a decline in the near future these prices must further advance.

Table II.

		Aug. 4, 1914	To-day
Galv. "East Lake" Shingles	per sq.	5.00	5.50
Painted "East Lake" Singles	per sq.	3.50	3.75
Galvanized Siding	per sq.	3.95	4.45
Painted Siding	per sq.	2.75	3.00
28 G Galv. Corr.	per 100 sq. ft.	4.00	5.00
22 G Galv. Corr.	per 100 sq. ft.	6.75	8.50
28 G Painted Corr.	per 100 sq. ft.	3.00	3.25
22 G Painted Corr.	per 100 sq. ft.	5.25	5.75
Metallic Ceiling	per sq.	4.00	4.00
10-in. O. G. Trough	per 100 ft.	2.97	4.15
3-in. Conductor Pipe	per 100 ft.	3.90	5.22

From the above information it is plain that under the heading of "Miscellaneous" we encounter a number of items that cost appreciably more than they did a few months ago. Whether these increases are offset by the gains at other points, or whether they can be balanced against the general willingness of contractors to do business these days on a very narrow margin, can only be determined when the exact conditions surrounding any individual case are known. Looking at the matter superficially, it seems to be quite possible that this may be the case. Further items under "Miscellaneous" will be considered in our next issue.

(To be Continued.)

What promises to be an important new development in roofing material for homes, is being shown by Bird & Son, Hamilton, Ont., who operate the largest factory for roofing and wall boards in Canada. It consists of an asphalt-saturated felt base with crushed slate surface, and made twice the size of an ordinary shingle. It is claimed for the shingle that it is not only as handsome as slate, but that it is economical as to cost, very durable, resists fire, and is easy of application on account of uniform size. The new shingle is being marketed in conjunction with this firm's paroid roofing and Neponset wall board.

The Construction of Highway Bridges

More Careful Consideration of Bridge Design and Construction as a Factor in Improved Highways

By Lucius E. Allen*

A consideration of any scheme of highway development must include as a component part of such system its highway bridges, which in many highways bears no small part of the total cost of the road. In view of this fact, a careful study on the part of highway officials and engineers should be given to the designing and construction of bridges that in point of cost and durability combined with the utmost safety will best conform to present and future conditions upon our highways.

While the wearing surface of the roadway will wear out and require renewal from time to time, the bridge structure should be so constructed as to be practically permanent. To attain permanency in bridges as in other structures, requires not only careful designing at the start, but also the judicious selection of those materials best adapted for that particular bridge, and finally, experienced workmanship in combining the materials at hand into a finished structure.

Substructure Design

It would be of little interest to many members of this Congress to enter into a technical discussion of the engineering of bridge design, but there are certain facts common to almost every bridge that is to be constructed, that have an important relation to the life of a bridge, which should be of interest to everyone connected with highway work. One common error often made in the construction of a bridge is the lack of attention paid to securing a good foundation. It matters not what the superstructure may be, whether of steel or reinforced concrete, unless the foundation is sound, the superstructure may be damaged beyond repair. Accurate and careful soundings should always be taken to determine the character of the bottom upon which the abutments or bridge piers will rest. This may be done by the use of steel rods driven until either solid rock or a sound foundation is found. In some cases a wash drill outfit may be used consisting of a drill point attached to short sections of iron pipe which may be connected together as the drill penetrates into the soil. Water is forced through this pipe by means of a force pump and in this way the character of the sub-soil can be determined. In rivers or streams where ice conditions are severe, it is usually necessary to trench into the rock bottom so that the pier will have proper and secure footing to withstand ice jams. This also prevents underwashing of the pier from the currents existing in the stream.

As a general rule it is not advisable to construct the arch type of reinforced concrete bridges upon anything less than a good rock foundation or its equivalent. Where the foundation conditions are not suitable for the use of the arch type of bridge, the girder-beam type of reinforced concrete may be used. In this type, should settlement subsequently occur in the abutments, the concrete slab would still be intact, the reinforced-concrete beams acting in a similar capacity to the steel girders in the girder type of steel bridge.

*Engineer County of Hastings, before the Canadian and International Good Roads Congress, Montreal.

Due attention should also be given to the size and type of piers and abutments. In some cases it is economy to use reinforcement in the piers and abutments, thereby reducing the size of the pier or abutment and adding to its strength and ability to withstand heavy lateral strains. The wing or reventment walls connected with the abutments should be constructed of such height and length as to prevent backwashing of the abutment, and also retain to a proper slope the earth approaches to the bridge. In some cases it is advantageous to start the growth of willows along the edge of the stream adjoining the wing walls to further restrict washing, etc. It is important to remember that as in many sections of this country the forests are being depleted, the watersheds of many rivers and streams, while not being changed in area, yet the spring runoff of water is much quicker than formerly, thereby increasing the danger of washouts to bridge foundations. It is therefore good practice to anticipate such conditions, and so construct the foundations of our bridges as to withstand the test of time.

Selection of Type of Bridge

Unlike highway construction, there can be no standard type of bridge that will be adapted for every locality. Local conditions should in every case govern the choice or selection of the type of bridge. This will in most cases resolve itself into a consideration of three points:—length of span and head room; character of river or stream as well as traffic conditions; and the character of the foundation available.

The length of span will depend largely on calculating the relative cost of long spans with fewer piers, or shorter spans with an increase in the cost of the foundation. The cost of the superstructure should be made to balance as nearly as possible the cost of the substructure. In some cases the lack of head room or elevation of the approaches to the bridge will prevent the adoption of the reinforced concrete arch type, in which case the girder-beam type may be used to advantage.

If steel is selected as the best material to use for a bridge, the length of span will determine the type of truss. Usually bridges with spans up to 75 to 80 feet the low truss type is the most economical, above 80 foot span the high truss type is usually used. The use of pin connected truss bridges is being displaced to a large extent to the use of riveted sections, either singly or made up of angles, channels and plates.

The girder-beam type of reinforced concrete bridge above 45-foot span is not usually as economical as the arch type. In the construction of reinforced-concrete bridges too great care cannot be exercised in the selection of the best materials entering into the concrete. Many concrete bridges have been made failures simply from the use of poor material or inexperienced workmanship. The work of pouring the concrete should be as continuous as possible, especially in the slab or rib of the arch. A careful check should be made during construction to see that every piece of steel reinforcement is placed in its proper location in the bridge. Many times a careless workman, not realizing the importance of the location of a steel reinforcing bar, will displace it from its proper location, thereby weakening for all time the strength of the bridge. Sufficient camber and grade should be given the concrete floor slab to drain the water from the bridge floor. If solid concrete side walls are used, short sections of iron pipe may be placed at the bottom of the floor and through the side wall to drain the water quickly away from the floor.

Traffic

As before stated, the character of the river or stream will in many cases determine the best type of bridge adapted for the locality, but the character and amount of traffic passing over a bridge should always be taken into consideration in determining the character and width of the bridge. While it is difficult in all cases to anticipate future traffic conditions on a given highway, on main connecting roads or roads leading into large cities or towns, the traffic is very likely to increase. For ordinary country roads, a clear roadway of sixteen feet is sufficient for ordinary traffic. For main roads, where the motor traffic is heavy a bridge width of twenty feet is not too great. In England many of the old masonry arch bridges have in recent years been widened to accommodate the large increase in traffic.

It may be of interest to note that in a report presented by Mr. H. Howard Humphreys and Mr. W. J. Taylor, County Surveyor, Southampton, England, at the Third International Road Congress in London, it is stated that of thirty-three Engineers of County Councils, who furnished information regarding the use of reinforced concrete for bridge work, eighteen reported that reinforced concrete had been used for the construction of bridges anl culverts carrying main roads within their respective counties, while others were considering its use.

The reasons chiefly advanced by these county engineers in favor of reinforced concrete bridges, as compared with steel and masonry were "economy in first cost" and "economy in maintenance." If the floor slabs of reinforced concrete bridges are kept properly covered with from five to six inches of gravel or crushed stone, there will be little wear on the concrete surface of the slab itself.

Artistic Design

The artistic design and finish of a reinforced concrete bridge should also not be neglected. With little if any additional expense artistic effects may be given to the concrete sidewalls by panels or open balustrades and suitable panelled end posts. If surfaced lumber is used for forms and the forms are removed before the concrete is too hard, the surface can be brushed and given a uniform appearance which will add much to the general effect of the bridge structure.

If steel has been chosen as the best material suited to the locality, the engineer for the municipality should prepare suitable plans and specifications which may be submitted to the various bridge builders for tender. The old practice of allowing each bridge builder to submit his own plans should be avoided, as in this way there is no uniformity of design, and many times price was the main consideration. The fabrication of the steel work should also be inspected, especially the riveted connections. While ordinary shop riveting is usually well done, the riveting done in the field in erecting the bridge is often poorly done. All rivets after being driven and inspected should be immediately painted in the field, previous to the painting of the entire bridge. Two coats of paint in the field in addition to the shop coat should be given the steel work, each successive coat being of a different color to insure every portion being covered.

Too much stress cannot be put upon the matter of painting steel bridges. Many steel bridges in Canada which when constructed were first class bridges, through neglect to properly repaint them have practically been destroyed. The speaker has examined some steel highway bridges which were constructed from twelve to fifteen years ago, which have had to be replaced by new bridges owing largely to the lack of proper painting. Steel is not often put to a more severe test than when used in bridge work, the action of moisture, water, the acids from the bridge floor, etc., all tending to contribute to rapid corrosion unless protected by paint.

Bridge Floors

The matter of the best type of floor covering for a given bridge is also of great importance. While the use of concrete as a floor covering adds greatly to the weight of the floor system, and thereby increases the size of the trusses, etc., it is generally considered to be better than wood floors on account of the lower cost of maintenance. On main highways, or in cities, a combination of concrete and wood blocks makes a very durable bridge floor. The wood blocks should be creosoted, and the joints filled with pitch or asphalt to seal the joints. One advantage of wood block bridge floors is a reduction of vibration due to traffic, as well as being noiseless.

The capacity or safe load that a steel bridge is designed to carry is an important factor, and should be given attention before designing the structure. The future traffic requirements should again be borne in mind, as it is much easier to design a bridge for a 20-ton moving load than after having been constructed to reinforce or strengthen it for increased loads. Owing to the increased use of heavy road making machinery, such as tractors, road rollers, etc., which pass over bridges, it is necessary to design the bridge to safely take a maximum load equivalent to the weight of this machinery.

Capacity

The load capacity for different highway bridges may very conveniently be divided into two or more classes, depending upon traffic, and ranging from bridges capable of carrying ten tons up to twenty tons or more, which will ordinarily be sufficient for any heavy moving load as above mentioned. Allowance should also be made for decrease in strength due to age, so that at the end of, say, fifty years, what was originally designed as a 20-ton capacity bridge, may have fallen to 15 tons loaded capacity.

There are many other details which time will not allow me to mention that must be considered in selecting and constructing a highway bridge that combines economy of design with permanency. It is, however, a source of much gratification to highway engineers, that more careful attention is being given to this important branch of highway work than formerly, and great advancement has been made within the past few years in methods of construction, so that when the construction of a great Canadian national highway from east to west is commenced, as we believe it will be, the construction of its bridges will conform in beauty and permanency with that if the highway itself.

Mail Order Building of the Robt. Simpson Co., Mutual Street, Toronto

WORK on the new Mail Order Building and Warehouse of the Robert Simpson Company, which is to be completed and ready for the fall trade, is advancing rapidly. Profiting by the splendid weather, the general contractors, Wells Brothers, have been rushing the work, and at the present time are pouring concrete on the third floor. The building is the result of the increasing demand for larger accommodation due to the growth of the mail order business.

The building is situated on Mutual Street, just north of Wilton Avenue, and occupies the whole site 279 feet by 115 feet 3 inches. It is of fireproof construction, reinforced concrete on seventy-eight concrete caissons, which go to rock, with brick panels; is eleven storeys high, and in addition has two mezzanine floors. The Mutual Street elevations on all eleven floors except the first have the concrete columns set well back from the front wall, and show an unbroken expanse of glass between the two corner towers which surmount the entrances. On the west elevation the building will back up against the old warehouse building; the concrete parapet of the old building, which is five storeys high, will be removed to roof level, the roof patched, and space between the two buildings closed off. Thus the west elevation of the new building will have windows only above the fifth storey.

The main entrance is off Mutual Street at the south end, and the employees' entrance is also off Mutual Street at the north end. The main entrance has double plate-glass doors, with a transom above, and over all a frieze with a granite name-plate bearing the company's name. The entrance vestibule, which is very spacious, has a tile floor with marble wainscot and trim. Through the entrance vestibule the lobby, also tiled floor and trimmed with marble, opens to two passenger elevators and contains the inquiry bureau.

The ground floor plan shows on the south side a paved driveway, the Retail Receiving Court, with a platform with freight elevators at each end. On the west side is a similar driveway, the Retail Shipping Court, with an 8-ft. trucking walk beside it, also paved; and on the north side the Mail Order Shipping Court, with a platform with freight elevators similar to that on the south side. The concrete columns around these courts have cast wagon bumpers, with steel guards to protect them from deterioration. A steel stack for the boiler room is built up on a concrete foundation on the south-west corner of the building.

The first floor storey is 18 ft. 1 in.; the second is 16 ft. 4 ins.; and the remaining floors 12 ft. in height. Over the area-ways on the first floor is a mezzanine floor with a 7 ft. 4 in. ceiling, and on the second floor is a similar floor. The second floor plan, which is

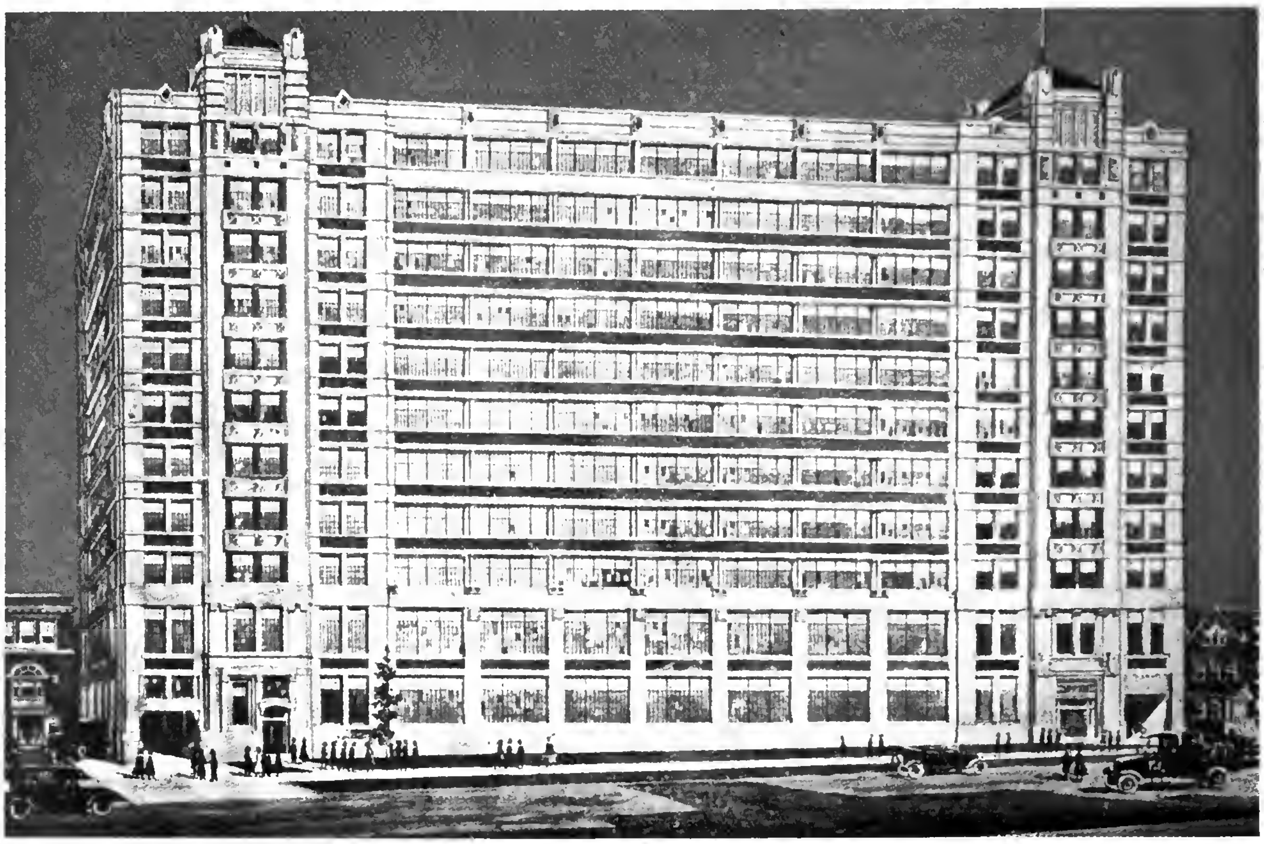

Fig. 1 The Robt. Simpson Co's. New Mail Order Building on Mutual Street, now under construction.

Fig. 2.—Ground Floor Plan of the New Robt. Simpson Mail Order Building Showing Arrangement of Foundation Piers, and Shipping Courts.

typical of the remaining floors except the top one, shows the two passenger elevators near the main entrance vestibule, with a flight of stairs beside; fire escape stairs in south-west and north-west corners inside the building; a pair of stairs leading from the employees' entrance; freight elevators at each end of the building; lavatories in the south-east and north-east corners of all floors. On the eleventh, or top, floor is the elevator machinery and the water storage tanks for the water system. There are two square 9,000-gallon tanks fed from a 40,000-gallon tank on the roof, and in addition to these two 3,000-gallon tanks in the machine rooms.

The roof is five-ply composition and gravel, 3/8 in. to 1 ft. pitch, made with 1½-in. grout on cinder fill on ceiling slabs. The roof is counter-flashed with galvanized iron, at all vertical walls and all copings are cast concrete. The four penthouses over the elevators containing the elevator machinery, have concrete floors, brick walls, moped cast concrete copings, and sky-lights. The tower roofs are built of steel angle irons covered with copper, with copper gutters.

The floors throughout the building, except the mezzanine floors, which are hardwood, are concrete. All doors and elevator doors are fireproof; steel stairs, diamond pattern, with safety tread; windows, leaded glass, steel sash; sills, cement, poured after sashes are set. The building is equipped throughout with a sprinkler system.

The building, which will cost $750,000, was designed by Max Dunning, Chicago (Burke, Horwood & White, local representatives). The general contractors are Wells Brothers, and the following subcontracts have been awarded: plumbing, heating and sprinkling, Purdy Mansell; glazing and glass, Imperial Glass Works; plastering, F. G. Roberts; ornamental iron, fireproof doors, etc., Canadian Ornamental Iron Company; elevators, Otis-Fensom Elevator Company.

The Electric Zinc Company has constructed a plant at Welland, Ontario, for the recovery of refined zinc from zinc oxide. It is intended, eventually, to treat the zinc ores from Notre Dame des Anges, Quebec, at this plant.

Contractor Offers Some Good Advice

Mr. Frank Gilbreth, the New York contractor, who built several large buildings in San Francisco after the big fire, has summarized his views on steel and concrete construction as follows:

1. A steel frame, properly painted and buried in masonry, will not rust enough in thirteen years to affect its strength any measurable amount.

2. The better the steel is coated with mortar, the less it will rust.

3. Portland cement is better than lime mortar for imbedding steel to prevent it from rusting.

4. Unpainted iron rods buried in mortar composed of lime and a large proportion of Portland cement rust very little, certainly not enough to impair their strength.

5. Columns should be of such cross section that they can be thoroughly imbedded in Portland cement, avoiding a hollow column unless latticed and filled with very soft concrete.

6. Wherever possible, preference should be given to those shapes of steel that present the least surface to the action of rust.

7. If steel is not thoroughly cleaned from rust before it is painted, the paint will not greatly retard the progress of the rust.

8. It is much easier to cover steel thoroughly with concrete than with brick masonry. If brick masonry is to be used, the bricklayer should thoroughly plaster the steel work ahead of the brick work.

9. The quality of the paint used, though important, is not so important as surrounding every part of the steel with Portland cement.

10. Interior columns do not rust as much as exterior columns.

11. Cinder concrete does not injure to the slightest degree a steel floor beam that has been painted.

12. No pipes or wires should ever be placed behind fireproofing, as they will buckle from the heat and push off the fireproofing.

Wall Plaster and Gypsum Products

The Production, Chemical Constitution, and Building Properties of Gypsum

Gypsum, the material used so extensively at the present time in building construction, chiefly for wall plaster, was the main subject of a paper on "Plaster and Gypsum Products," delivered by S. G. Webb, secretary of the Gypsum Industries Association, Inc., before the New York State Builders' Supply Association. Mr. Webb's paper deals with gypsum, its occurrence, its composition, its manufacture, its uses, and some of its products.

To begin with, gypsum is one of the oldest-known building materials and is found as the material on which mural decorations were placed in the tombs of the Califs in Egypt, erected over 4,000 years ago, and to-day, in the pyramids of Egypt it is found in the form of plastering on the surfaces of walls in the interior chambers, as solid as the stone upon which it is placed.

Gypsum is the geological name for hydrated sulphate of lime and is composed of lime in chemical combination with sulphur radical and water, the water being in the form of water of crystallization. It is found quite lavishly distributed over the earth's surface and occurs as rock, which is either in the form of veins below the ground or in masses near the earth's surface covered with only a thin layer of soil.

In the United States it is found in twenty-three states, including Alaska. The total amount mined in these states during 1914 was 2,476,465 tons. A part of this production of gypsum, amounting to 443,687 tons, was used without calcining as an ingredient for Portland cement, in paint and as land plaster. The remainder of the output was calcined and sold in the form of wall plaster or manufactured into gypsum blocks, gypsum plaster boards and other structural forms.

Production of Gypsum

In the production of gypsum, New York State produced the largest quantity, Iowa ranking second and Michigan third, and, therefore, the building supply dealers of New York State are peculiarly interested in this material for the reason that not only is it produced in the State of New York, but is produced in larger quantities in this State than in any other part of the United States.

In addition to the gypsum produced in the United States, a considerable tonnage was mined in Nova Scotia and New Brunswick and shipped to calcining mills located on the Atlantic seaboard, at New York, Newark, N.J., Newburgh, N.Y., and Chester, Pa. The quantity so imported from Canadian points amounted in the year of 1914 to 369,214 tons, making a total of material manufactured and used in the United States of 2,845,679 tons.

It will be noticed, therefore, that not only does the State of New York produce the largest amount of the domestic production of gypsum, but it also uses up the greater part of the gypsum imported from Canada in the eastern mills.

Chemical Conversion

The gypsum to be converted into plaster and manufactured articles, such as gypsum block, gypsum board, etc., has to be calcined into plaster of Paris. This is effected by crushing the gypsum rock and then grinding it to a very fine powder and placing this powder in what are known as kettles and subjecting the material in these kettles to external heat. In this way some of the water of hydration is liberated, which is approximately fourteen per cent., leaving about seven per cent. of water of hydration still remaining in the material.

The gypsum is thus converted into plaster of Paris and this plaster of Paris is mixed in mixing mills with ingredients such as wood fibre, sand, hair, retarder, asbestos fibre, or combinations of these materials, to form wall plaster. In the case of neat gypsum wall plaster, the sand is omitted. Such plaster is known as neat gypsum plaster and when the plasters are ready for use, they are known as ready mixed gypsum wall plasters.

It may be well to consider the qualifications of gypsum wall plasters, which have been responsible for the very great and rapid growth of the use of gypsum or hard wall plasters, as illustrated by the fact that the gypsum mined in the United States has grown from 90,000 short tons in 1880 to 2,476,465 short tons in 1914. Gypsum plasters must, therefore, possess distinctive merits to bring about such a wonderful increase in their use.

Qualities

I will mention some of these qualifications, not necessarily in the order of their importance, as follows:

First—Hardness; Plaster of Paris is a hydraulic cement which resumes the form of gypsum or hydrated sulphate of lime when water is added to it. It thus "sets" or becomes hard and is so hard that it will withstand a breaking pull of 100 or more pounds per square inch and this qualification of hardness acts as a valuable means of stiffening or strengthening the building in which it is used, particularly in the case of frame buildings.

Second—Sanitation; It is sanitary because of its very hardness, this hardness being throughout the entire mass of plaster, the hydraulic or setting qualities of the plaster occurring throughout its entire mass. This gives a wall surface in which injurious disease germs or objectionable insects cannot find lodgment, and it also offers an impediment through which larger vermin find it impossible to make holes.

Third—Durability; I have mentioned the fact that gypsum plaster is found to-day in perfect and hard condition as the covering of many of the walls of the chambers of the Pyramids in Egypt and that it has been there for upwards of 4,000 years. Under the city of Paris, France, gypsum is found in large quantities and has been used there for plastering and structural purposes for hundreds of years—the name of plaster of Paris being derived from this fact. This qualification, therefore, of durability of gypsum wall plasters means that they resist wear and tear in a building very efficiently.

Fourth—Quick Setting and Quick Drying; Gypsum wall plasters can be used during any time of the year, and will set and become hard and dry out very quickly, so that the owner can have the use of his building in the least possible time. He can also proceed with his painting and decorations with very little, if any, misgiving that these will be injured by too early application.

Fifth—Convenience in Handling; The fact that gypsum plasters are usually marketed packed in bags in the ready mixed form, necessitating only the plaster being mixed with water at the building, enables the dealer and the builder to handle in convenient packages only the exact amount of material that is required, and in a minimum amount of space in the building. This great convenience in handling and using has been a considerable factor in increasing the popularity of gypsum hard wall plasters, and is a very good and real reason why the dealer can handle the ready mixed gypsum wall plasters to considerable advantage.

This is a brief outline of some of the principal advantageous qualifications which gypsum wall plasters possess, about which there is no real dispute.

Corrosion of Metals

I desire to refer at this time to one question that is frequently raised as an objection to the use of gypsum plasters, and that is the assumption that gypsum tends to corrode metal. Gypsum is a neutral salt, that is, it is neither acid nor alkaline, and, therefore, cannot be corrosive when in contact with steel or iron. This statement has been amply demonstrated by experience, namely, that in the absence of damp conditions there is no corrosion of the metal when in contact with gypsum plaster. In the earlier days of gypsum plaster manufacture, however, it was the practice to use some acids as retarding agents, and it was because this acid, in conjunction with damp conditions, in some cases caused corrosion, that there grew a certain amount of prejudice against gypsum in this connection. The bugbear, therefore, of corrosion may be properly dismissed. When corrosion occurs on metal which is surrounded by gypsum plaster, it is generally found that damp conditions would bring about corrosion of the metal in any event, and whether Portland cement or lime was the plastering material used instead of gypsum. Such cases are due to the oxidation of the iron from the combination of dampness and oxygen gaining access to the metal, and are not caused by anything in the gypsum.

Is Gypsum "Noisy"?

Another question which is frequently raised as an objection to the use of gypsum plaster is that it is "noisy." The fact is that gypsum plaster is no more "noisy" than any other plastering material. I recall very well making an examination of the New England Conservatory of Music in Boston, the walls between the classrooms of which were constructed of double gypsum blocks, separated by an inch space in which was hung a sheet of Cabot's seaweed quilt. The outside faces of the walls forming the interior faces of the walls of the rooms were plastered with gypsum hard plaster. In the earlier use of this building a great deal of complaint had been made about the noisiness of these rooms by the professors conducting the musical classes, until some bright person was able to draw a distinction between echoed sound and transmitted sound. They then placed rugs on the floors, draperies at the windows and tapestries on the walls, and this reveberated sound ceased to exist; and then it was that they found that no sound whatever passed through the walls from room to room. In the designing of buildings it is frequently found that there are pipes, air ducts or openings permitting sound to pass from room to room or from floor to floor, and when such sounds are noticed, immediately the gypsum plastered walls, which are what are seen in the room, are blamed for the noise, and gypsum plaster is said to be "noisy."

I recall another case where the owner of a two-storey brick business building in a small town in Ohio improved one of the two stores on the street level and then rented it as a drug store. He put tile on the floors, covered the walls with cases with glass fronts, and put a metal ceiling over the existing plastered ceiling. After he had done all this he found that the words spoken in ordinary tones in the store were clearly heard in the Masonic Hall immediately above this room and vice versa, and so bad was this condition that the Masonic lodge contemplated cancelling its lease. The other store on the street level was a clothing store, which he did not improve. It had wooden floors and plaster ceilings, and clothing was exhibited throughout the store. Now notice the difference. No word spoken in that room could be heard in the hall above, which was occupied as a Knights of Pythias lodgeroom, and neither could any word spoken in the Knights of Pythias' room be heard in the clothing store beneath. In considering this question of sound, therefore, it is necessary to be acquainted with the conditions and find out whether there are other conditions responsible for the sound trouble. You will find that invariably there are.

Gypsum Products

I see that the subject assigned to me includes gypsum products. I hope I may be pardoned therefore, if I say a word or two about other gypsum materials that are or should be of considerable interest to the building material dealer. There is gypsum plaster board, the use of which is growing tremendously as its usefulness is recognized and I question very much whether there is any dealer within hearing of my voice who does not at this present time find it to his advantage to sell plaster board.

In addition to the advantages there is from a business point of view in selling plaster boards, you are undoubtedly interested in the fact that plaster boards have a very real value in preventing the spread of fire. Many cases might be cited of fires that have occurred where the damage has been kept to a minimum because boards have been used as a lathing material. In selling plaster boards therefore, you are helping the cause of fire prevention.

In recent years a very large growth has occurred in the use of gypsum plaster blocks, principally for the construction of partitions in the so-called "fireproof" type of buildings. Many tests have been conducted by the Underwriters' Laboratories and other institutions, which have demonstrated that gypsum block partitions have a very high efficiency in fire resistance and so its growth has been rapid until to-day in the country at large probably sixty times as much gypsum plaster blocks are used as were used only eight years ago.

This growing appreciation of the value of gypsum plaster blocks is leading to recognition for the protection of important vertical openings in buildings, such as elevator shafts and for steel protection and more recently, as book tile for roofs, placed between the steel frames or steel perlins of steel roofs. A very considerable area of structural floors are now being used made of gypsum in poured form reinforced by steel. In this connection, it will be interesting to you if I refer to what happened in Paris, France, during the days of the Commune immediately following the Franco-Prussian War. As you know, efforts were made to burn Paris, but these efforts were futile and it is a coincidence, if it can not be proved to be directly the reason for this failure to burn up Paris, that ninety-five per cent. of the floors of buildings in Paris were and are to-day, constructed of poured plaster of Paris; in other words, reinforced gypsum.

The Improved Highway as a Tactical Unit in National Defence

By P. S. Bond, M.A.S.C.E.*

The usefulness in war of a substantial system of highways can scarcely be overstated, but it can be misunderstood and frequently is. Our freedom from wars, during long periods, has made the term "military road" little more than an historical phrase in America. It calls to mind the Cumberland pike and suggests the conditions of military enterprise that gave rise to our constitutional provision for federal military roads.

Those conditions antedate the railroad. In the present state of affairs the longer hauls for the assembling of soldiers, munitions and supplies will almost invariably be made by rail. Military considerations do not call for long single lines of road through the interior of the nation so much as for intensive systems of parallel and intersecting roads in the probable zones of actual warfare in case of attack by a foreign enemy.

Military Roads

To appreciate the tremendous usefulness of such road systems, it may be necessary to review some of the conditions of modern war as exemplified in Europe to-day. In speaking of innovations, I use the word with respect to popular United States conceptions of war, which are still largely founded on the civil war of the sixties. The European war has really developed very few innovations, from the standpoint of the military student. Attacks by gas and liquid fire, effective as surprises, have been among these few. The general nature of the struggle was either anticipated by military men or actually demonstrated in the other wars of the last two decades. I wish particularly to refer to some phases of modern war with reference to the use of highways.

While less reliance than formerly is placed upon permanent fortifications, trench warfare between nearly equal forces tends to develop a condition of deadlock, in which the tactics are similar to those of a siege. Hence, the routes of supply do not, under certain conditions, vary as much as in the old days of open fighting when one army would pursue another half across a continent on foot.

Nature of Military Traffic

Not only are routes of distribution more nearly permanent, but the volume and weight of the traffic is such as to justify and require the most substantial kind of highways. Larger armies eat more food. Larger and more intricate guns consume immensely more ammunition. The British army in Belgium is said to have fired more shells in a single day than were used in the entire Boer war. These are transported from the railroad terminals to the place of consumption very largely by motor truck and the effect on any but the most substantial roads can be imagined.

Add to these conditions the mobility now required for very heavy guns. It can be seen that the placing and replacing of ordinance weighing many tons per piece—the saving of guns in case of a sudden retreat—would be virtually impossible under the conditions that prevail on most United States highways during long seasons, or would impose the heaviest possible tasks upon the engineering arm of the service.

We have pictures showing the kind of improvised roads upon which the Germans have been compelled to rely in Russia. They follow the principles of the old American corduroy road, with a foundation of stringers and transverse logs, on which are laid brush and dirt. The contrasting advantages of level, durable road surfaces, prepared in time of peace with an eye to the exigencies of war, are so striking as to make comment unnecessary.

Motor Truck in Tactics

But the greatest advantage of motor trucks and suitable motor roads has yet to be mentioned. To appreciate it, one must bear in mind the broad nature of battle tactics. War is not unlike football. An army must hold the foe in check at all points on the line and rely for its success upon smashing attacks by the concentration of troops at some particular point. In the old days the plan of attack was often concealed from the enemy until the moment when it was sprung. Distance and natural obstacles to vision made it possible to work out a manoeuvre with comparative leisure. To-day the hostile aeroplane hovers overhead and conveys prompt information of the concentration of any considerable body of troops at any given quarter.

To render such an attack effective, it is therefore necessary to make it a sudden attack, like the dash of the backfield in a football game. To be able to move a whole division by truck and auto to a critical point at a rate of twenty or thirty miles an hour would greatly facilitate both offence and defense. It is said that the battle of the Marne was won by the sudden concentration of French troops, using motor transport over the splendid chaussees of France, upon the German left wing.

System of Roads

One road will not suffice for this variety of tactics, although one is better than none. The ideal would be a number of parallel routes traversing the line of battle, with frequent cross roads to permit the distribution of reinforcements at any desired point or points. In war there is only one rule for success, and that is to oppose a lesser force with a greater force at the crucial point in the conflict. This does not mean that the largest army always wins, for the largest army may have three-quarters of its numbers out of action through lack of generalship or failure of transport facilities. Mobility can take the place of numbers much better than numbers can be made to take the place of mobility. When this fact is digested, the

* Major, Corps of Engineers, U. S. Army.

immense tactical value of paving can be better appreciated.

The motor can thus lessen the fatigue of forced marches and increase their possible radius five fold or more. It is also probable that motors will take over part of the work of transport formerly accomplished by rail. There is considerable necessary delay in entraining troops and getting a clear track for their movement, so much so that the old rule was to undertake movements of thirty miles or less on foot, as being prompter than train service. With suitable roads and an abundance of motor vehicles, this line of demarcation might be placed at sixty or a hundred miles or more, depending on the particular circumstance of the case.

Efficiency of Brick Pavements

The unimproved highway is our weakest link today from the standpoint of military transport. America has the railroads. It has the autos and auto trucks. Whether the latter can be used, or whether we must go back to the age of the mule whacker and the dreary march rests with those who are responsible for our highway improvements. Any city within a hundred miles of our coast or frontier may some day be the base of military operations that will put its surrounding highways to the severest test. Very few would meet it creditably. Cuyahoga County, surrounding Cleveland, would offer a better opportunity for modern manoeuvres than any similar locality with which I am familiar. The brick road, properly constructed, stands high in the estimation of army men for such purposes as I have been describing.

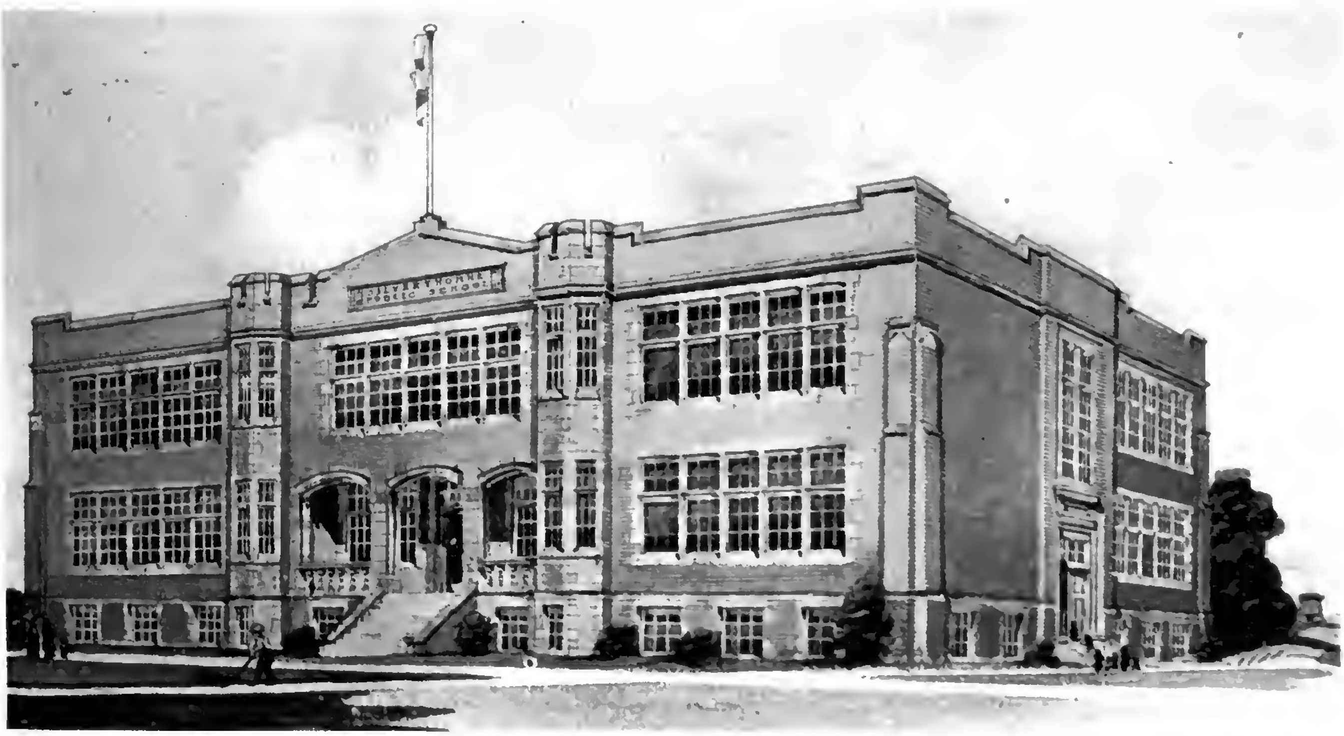
In a military crisis such a system of roads would much more than pay for itself in the saving of other forms of military expenditure. Considering also how they conduce to the wealth of the nation in times of peace, there seems to be no possible argument against this phase of preparedness.

Silverthorne Public School, Mount Dennis Ont., Under Construction

Contracts have been awarded for a new public school for School Section No. 28, Mount Dennis, Ont., and work has been actively commenced.

The new school is to be semi-fireproof in construction, to be built of common stock red brick, with stone trimmings and copings; foundations and footings are concrete. The building will be two storeys and basement high, to have five standard classrooms, kindergarten, a principal's and teachers' room. The basement has provision for large playrooms for boys and girls, the usual room for fuel and heating equipment, and lavatories. The classrooms will have mullioned, leaded glass windows, hardwood floors, slate blackboards, and are all provided with a separate cloakroom. The corridors on the first and second floors run the width of the building, and will have terrazzo floors. The basement floors are concrete. The stairs will be steel with mastic treads. The system of heating and ventilation is to be by forced steam with electric fan ventilation. A more complete description of the school will be furnished on completion.

The school was designed by S. B. Coon & Son, architects, Toronto, and the following contracts have been awarded: masonry, Albert Webb; carpentry, Hudson & Mosely; heating, plumbing, and ventilation, George Sainsbury; steel, McGregor & McIntyre; steel sash, Henry Hope & Sons; plaster, George White; painting, Fells Bros.; electric wiring, Moon & Company; terrazzo floors, Italian Mosaic and Marble Company.



Silverthorne Public School, Mount Dennis now under course of erection.

Canadian Railway Statistics, 1915

Dominion Roads Show Creditable Record Despite Adverse Conditions—Gross Earnings, $199,843,072.13

Returns of the railway statistics of the Dominion of Canada for the year ending June 30, 1915, are to some extent rather remarkable for the first year of the war. Receipts show a decrease, but the operating expenses show a decrease also, while the total mileage shows an increase.

Though the railways were hit hard by the war, due to the scarcity of freight for transportation and the decreased tourist trade, but more particularly by the poor western crop of 1914, they showed a remarkable adaptability in adjusting themselves to the adverse existing conditions. With the record crop of 1915 to handle, the increasing activity in industrial life, especially in munition work and trades pertaining thereto, we may safely say that the lowest point has been reached and passed, and that returns for the present year will show a big increase in receipts and gross earnings.

There was an unprecedented increment in the mileage operated, reports showing an increase of 4,789.9 miles, as compared with 1,491.01 miles increase in 1914. This addition brought the total mileage in Canada up to 35,582.44—a mileage which places Canada in the first place among the nations on the basis of railway mileage per capita, and fourth among the nations in regard to the total mileage, being exceeded only by the United States, Russia and Germany. There was also 1,593.4 miles of line reported as still under construction. Ontario led in the increase in mileage with 1,447.53 miles, with Alberta a close second with 1,122 miles.

The capitalization of railways officially classified as being in operation stood at $1,875,810,888 on June 30, as against $1,808,820,761 in 1914—an increment for the year of $66,990,127. There was an increase for 1915 of $2,977,412 in consolidated debenture stock, an increase of $69,322,267 in funded debt, and a decrease of $5,300,552 in stocks. The falling off in stocks was due to an adjustment of capitalization by the Canadian Northern and its subsidiary corporations. The total amount of cash aid given during the year was $5,059,-284.17. This contribution was made up as follows:—by the Dominion, $4,644,664.17; by the provinces, $414,620. Land grants by the Dominion Government and the province amounted to 43,929,312 acres.

Traffic

The public service of Canadian railways in 1915 was represented in the carrying of 46,322,035 passengers and 87,204,838 tons of freight. As compared with 1914 there was a decrease of 380,245 in the number of passengers carried, and a decrease of 14,189,151 tons in the movement of freight. It should be understood in connection with the number of passengers carried, that in 1915, for the first time, the report of the Canadian Northern Railway system includes traffic attaching to the Niagara, St. Catharines and Toronto Railway heretofore classified with electric railways. The number of passengers carried by this electric line was 4,771,004. Earnings from passenger train service—including ticket sales, mails, express, baggage, etc., were $65,354,768.16, as compared with $72,564,203.20 in 1914. The record of passenger service for the year shows quite clearly that fewer people travelled by rail, and that the average journey was considerably reduced. These basic facts are reflected in lowered earnings and a smaller average number of passengers per train and per car.

Of freight, 87,204,838 tons were carried in 1915, which showed a decrease of 4,189,151 tons as compared with 1914.

Gross Earnings

Gross earnings for 1915 amounted to $199,843,-072.13, or $43,240,456.91 less than for 1914. This decrease was equal to 17.8 per cent. Operating expenses aggregated $147,731,099.47, which involved a decrease of $31,244,159.43, or 17.5 per cent. as compared with the preceding year. The ratio of operating expenses to gross earnings was 73.94, as against 73.63 in 1914. These figures show how flexible the railways were in adapting themselves to meet the adversity of the decreased traffic, the percentage of operating expenses to earnings increasing only a fraction of one per cent.

The difference between gross earnings and operating expenses, popularly regarded as net earnings, was $52,111,972.66, as compared with $64,108,280.14 in 1914. Gross earnings from the outside operations of Canadian railways were $20,332,305.65, as against $23,882,141.90 in 1914. Combining ordinary earnings and outside earnings, a total gross corporate revenue of $220,175,-377.78 is established for the year. After deducting operating expenses, the net earnings from outside operations in 1915 were $6,273,794.26, as compared with $4,097,338.28 for the previous year. The aggregate of net earnings from these two sources, as represented by the difference between gross receipts and operating expenses, was $58,385,766.92. To the foregoing should be added the income of railways from other sources than ordinary and outside operations, amounting to $14,111,482.85. With this addition the final net revenue would be $72,497,249.77. This total in 1914 was $82,134,693. The total revenue from passenger train service for 1915 was $60,699,934.82, made up as follows: passengers, $50,173,267.29; mail, $3,026,773.41; express, $6,059,384.72; other sources, $1,440,509.40.

The railways were perhaps the first industry to feel the shock of the war, and within the year the number of employees was reduced from 159,142 to 124,142. Yet, with this large decrease in men, the high standard formerly maintained on road-bed and equipment was not sacrificed. With the decreasing traffic the rolling stock was correspondingly decreased, the old deteriorated equipment being taken off, leaving only the better equipment. Fuel consumption was also very materially decreased, from 8,547,675 tons in 1914 to 6,903,418 tons in 1915; and with a lower cost per ton of $3.02 as compared with $3.12 the previous year, expenses were thus materially reduced. A striking feature of the fuel consumption was the increased use of oil by locomotives.

A large factor in the increased cost of maintenance has been the rising price of ties, and the increasing use of treated ties is the natural result of the excessive cost of untreated wood.

The number of accidents from train movement was ever so much less than in the previous year—360 killed in 1915, against 565 in 1914, and 1,578 injured in 1915 compared with 2,287 in 1914.

Electric Railways

Electric railways seem to follow pretty closely the steam roads; again the reports show an increase in the growth of the industry but a decrease in the revenue. During the year 50.51 miles were added to the mileage, bringing it up to 2,102.95. Capitalization increased from $147,585,342 in 1914 to $150,344,002 in 1915. Gross earnings amounted to $26,922,899.70, as compared with $29,691,077.21 for 1914. Operating expenses had a total of $18,131,842.18, as against $19,107,817.60 for the year preceding.

Reviving Activity

The crisis seems to be past; yet we cannot hope for some time to attain again the high-water mark of 1913. Especially in railway construction. According to the reports, there is only about 1,600 miles contracted for for the coming year. Railways are built on borrowed capital, and with the stringent state of the money market capital is at too high a premium to make financing an easy matter. Yet trade in general has responded to the confidence of the people, already the railways are beginning to make up the deficit, and the railways are a good barometer.

Canada is in a grand position to stand the strain of the war, and well adapted to take advantage of commercial opportunities when it is successfully terminated. For years immigration has aided both the railways and the country, and with the termination of the European struggle Canada should again experience a marked increase in immigration. Whether we build more railways or not in the near future, we are supplied in the meantime with sufficient mileage to develop the resources of the country—which should be our chief consideration.

Recommended Practice in Concrete Road Construction Adopted at Chicago

THE report of the Committee on Resolutions to the Second National Conference on Concrete Road Building, held at Chicago, February 18, contained a number of interesting conclusions. In an outline of the conclusions of the conference, the report gives a list of 12 salient features of practice. These are: (1) Drainage of the roadbed is vital; (2) subgrade must be of uniform density and should be compacted; (3) aggregates must be clean, hard and tough; (4) fine aggregates (sand) should be coarse and well graded; (5) a rich mixture must be used; (6) materials must be accurately proportioned; (7) mixing must be most thorough; (8) sloppy concrete must not be used; (9) in general, the use of reinforcement is justifiable; (10) inspection must be intelligent and thorough; (11) concrete must be protected from rapid drying; (12) pavements must not be opened to traffic too soon.

The following principles were adopted as representing good practice in the construction of concrete roads and pavements:

Materials.—Portland cement shall meet the requirements of the standard specifications of the American Society for Testing Materials, and tests should be made in accordance with the methods outlined by the American Society of Civil Engineers.

Aggregates.—Samples of materials should be submitted to the engineer for approval before orders are placed, and, if possible, laboratory tests should be made. If this is impracticable, field tests should be made. The different aggregates should be kept clean and separate. Aggregates to be used in the wearing course of two-course pavements should be placed on planks or some other means provided to keep them free from dirt.

Water.—A large supply of water is necessary for (a) sprinkling the subgrade; (b) mixing the concrete, and (c) keeping the concrete moist during early stages of hardening. For this latter purpose 25 to 30 gallons per square yard of pavement will be required during the summer months. Insufficient sprinkling is detrimental to the wearing qualities of the pavement.

Reinforcement.—The use of reinforcement is increasing. A coating of light rust will not be detrimental, but excessive rust, paint or other coatings interfere with proper bond. Reinforcement should be kept free from dirt and should be subjected to occasional tensile and bending tests.

Joint Filler.—Joint filler should preferably be of single thickness. Transverse joint filler should be cut to the crown of the pavement by the manufacturer when metal plates are used. A type of joint filler which will iron out readily under traffic is preferable for use in unprotected joints. A joint filler which will not bend easily when concrete is deposited against it is to be preferred.

Joint Protection Plates.—Metal joint protection plates should be properly bundled and wired by the manufacturer. Plates up to 20 feet should be shipped in single lengths. The exact length should be provided so that the contractor would not have to cut plates. In cutting plates for length, spacing between eccentrics on the installation bar should be considered to avoid interference with anchorage lugs on plates. The manufacturer should use particular care in crowning the bar to avoid the necessity for duplication of work by the contractor.

Drainage.—For roads, proper drainage may be secured through lateral ditches. For streets, as well as roads, tile drains may be used. They should be laid on each side of the roadway or on one side only, with cross drains leading thereto. Drainage trenches, if placed under the subgrade, should be completed before the final rolling.

Grading.—In general, fills should be made in thin layers, the depth depending upon the character of the material used. The fill should be allowed to stand for as long a time as possible, giving it an opportunity to settle before the pavement is placed on it. Deep fills should be allowed to settle through one winter whenever possible. Puddling will be found advantageous in compacting deep fills. Wetting and rolling should be performed when making a fill, in order to secure thorough compaction. Fills should never be made with frozen materials nor with lumps greater than 6 inches in their greatest dimension.

Subgrade.—The fundamental requirement of the subgrade is that it should be of uniform density so that it will not settle unevenly and cause cracks in the surface of the pavement. When the pavement is constructed on virgin soil, care should be taken to remove all soft spots. If laid on an old roadbed, even more care should be taken, as the subgrade is likely to be more compact in the centre than at the sides. An old roadbed should be scarified, re-shaped and rolled. The subgrade adjacent to curbs should be hand-tamped.

Forms.—Metal forms are preferred. When wooden forms are used they should of be at least 2-in. stock, capped with 2-in. angle iron, so constructed that sections can be lapped. Particular care should be taken to see that top edges of forms are clean, so as to avoid unevenness in the finished pavement.

Pavement Section: Thickness.—In view of the increasing use of the heavy motor truck and bus, it seems unwise to build pavements less than 6 inches thick at any point. In general, pavements should be thicker at the centre than at the sides. Alleys with an inverted crown and narrow, one-slope roads should have a uniform thickness. Wherever increased thickness can be secured without excessive cost to secure a flat or nearly flat subgrade, such increase is advisable.

Width.—The desirable width for a single-track road is 10 feet; for double-track road, 18 feet. The total width should be not less than 20 feet for single and 26 feet for double-track roads.

Crown.—The crown of roads and pavements should not be less than 1/100th nor more than 1/50th of the total width. Except in unusual cases, 1/100th is sufficient for country roads and 1/50th will be considered satisfactory for alley pavements. For city streets an average crown of 1/75th will generally be found sufficient and should not be reduced except on grades.

Joints.—Transverse joints should be placed across the pavement perpendicular to the centre line, about 50 feet apart. There seems to be a tendency to widen the distance between joints. Joints should extend entirely through the pavement as well as through the curb if integral curbs are used.

Longitudinal joint filler should be staked or otherwise securely held against the curb. Joint material should be placed around manholes, catch basins, etc.

The tendency of present practice is toward the omission of metal protection plates for joints. Plates are more essential in street pavements than in country highways. Plates for protected joints should be wired together with the joint filler and securely held in the installing bars, even when short sections of filler are used. Supports should be used when the pavement is of such width that the installing bar deflects. On wide streets every joint should be checked as to crown with sighting T's. When necessary to have plates in two sections, the contractor should arrange to have the manufacturer drill the abutting ends so that the plates may be wired or strapped together. As the plates do not fit tight to the installing bar, a ¼-in. shim is placed under each end of the installing bar to insure that the plates are not covered with concrete.

Mixing and Placing Concrete: Measuring.—It is recommended that a sack of Portland cement, containing 94 lbs. net, be considered the equivalent of 1 cubic foot. The method of measuring materials, including water, should insure accurate proportions at all times.

Proportioning.—The proportions should not exceed five parts of coarse aggregate, measured separately, to one part of Portland cement. The fine aggregate should not exceed 40 per cent. of the mixture of fine and coarse aggregates.

Aggregates.—Bank-run material shall not be used. Proportioning based on sieve analysis or by relative density tests is not practical for concrete roads except where laboratory direction is available. Where proper facilities are available, the above proportions should be varied as the tests warrant.

Mixing.—The ingredients should be mixed in a batch mixer of approved style and the size of the batch should not exceed the rated capacity of the mixer. The mixing should be continued for at least one minute after all the materials are in the mixer and before any of the concrete is discharged. The speed of the mixer should not be less than ten revolutions per minute. The time and not the number of revolutions should be the gauge of proper mixing.

Consistency.—The practice is to mix entirely too wet. The consistency should be such as not to require tamping, but not so wet as to cause the separation of the mortar from the aggregate in handling and placing.

Placing.—If the subgrade has been disturbed by teaming or other causes, it should be brought to its former surface and thoroughly saturated with water. The concrete should be deposited rapidly to the required width and depth. The section should be completed to a transverse joint without the use of intermediate forms or bulkheads, or a transverse joint may be placed at the point of stopping. If the mixer breaks down, the concrete should be mixed by hand to complete the section. Where reinforcement is used, it should be embedded in the concrete before it has begun to set. The concrete above the reinforcement should be placed within 20 minutes after placing the concrete below. In two-course pavements, the top should be placed within 20 minutes after placing the bottom.

Finishing.—The surface should be struck off by means of a template moved with a combined longitudinal and transverse motion. The excess material accumulated in front of the template should be uniformly distributed over the surface of the pavement, except near the transverse joint, where the excess material should be removed. The concrete adjoining the transverse joint should be dense and any depressions in the surface should be filled with concrete of the same composition as the body of the work. After being brought to the established grade with the template, the concrete should be finished from a suitable bridge, with a wood float to true surface. A metal float should not be used. Brooming of the surface is not necessary and grooves are objectionable, even on grades.

Retempering.—Retempering of mortar or concrete that has partially hardened, that is, mixing with additional materials or water, is strongly condemned.

Protection and Curbing.—Too rapid drying out, early exposure to low temperature or opening to traffic at too early a period may seriously damage the best concrete. Hot sun and drying winds are most liable to dry out concrete too rapidly, causing shrinkage cracks or a surface which will not wear well under traffic. The use of a canvas covering will be found effective in preventing this. Sprinkling should not be omitted during the day in case the surface shows a tendency to dry out. Where there is danger of freezing, sprinkling should be omitted and a covering of canvas or straw and canvas should be used. Placing concrete roads in temperatures at or near the freezing point is not advisable. Where such practice is unavoidable the water and aggregates should be heated and fresh work protected from freezing for at least ten days. Chemicals should not be used to lower the freezing point of the mixture. Concrete should not be deposited on a frozen subgrade.

Opening to Traffic.—Under most favorable conditions a concrete pavement should not be opened to traffic in less than two weeks. When conditions warrant, the interval should be at least four weeks.

One-Course Pavement.—Where the materials most readily available are such as to give good construction in one-course pavement, such construction is recommended.

Integral Curb.—The integral curb is recommended in preference to straight curb or combined curb and gutter. Precaution should be taken that the curb is thoroughly bonded to the pavement proper.

Specifications.—The standard specifications for pavements and roadways of the American Concrete Institute are recommended.

Building Construction and a Few Common Causes of Failures

Failures, whether in the building trade or in any branch of engineering, always furnish a peculiarly interesting subject for investigation; because from the failures and errors of the past present builders may gain experience and incorporate new ideas, which should result in a better class of buildings. "Dangerous Structures" was the subject of a practical paper along this line, recently read by W. G. Perkins, district surveyor, before the Concrete Institute, London. The following extracts from Mr. Perkins' paper in The Surveyor are interesting.

Causes of Failures

Amongst the causes of a dangerous structure are the following:—(a) faulty construction; (b) faulty materials; (c) faulty design; (d) decay and fatigue; (e) overloading; (f) removal of extraneous support; (g) wind pressure, shock, etc.; (h) fire and explosion, bombs.

I propose to enumerate a number of cases where failures have resulted from one or more of these causes; particularly (a), (b) and (c).

Perhaps few of us have had any experience with failures arising from faulty design and materials in modern structures, as a sufficient period has not elapsed for time to have done its work, but there are numerous instances in buildings erected by former generations.

We moderns are often called to account for the supposed inferior manner in which we build, being told that our buildings are not solid like those erected in "the good old times," that we have lost the art of making good mortar, etc. People who make such remarks have, I fear, only an acquaintance with the jerry-builder of the very bad type. The majority of buildings erected in London 100 to 200 years ago were constructed in a most inferior manner. The mortar appears to have been compounded with a fat lime, dry slaked, and, judging from the nodules of loam it contains, mixed with a good deal of the "top spit" of the field. Naturally such stuff has, and had, no binding qualities, and to this day is only so much dusty rubbish.

The bricks were badly shaped and easily broken, so much so that in taking down old walls one finds course after course of what appeared to be headers to be only "bats."

In many old buildings the main beams of the floors are placed diagonally and the loads from the roof and four storeys are imposed upon a pier of brickwork about 14 inches square. Needless to say, such piers have crushed.

Strangely enough, this kind of brickwork is always stronger in damp positions, the moisture having enabled the lime to a certain extent to set. Workmen refer to this state as being "water bound."

Again, I have found a wall of this period built with two skins of brickwork, 4½ ins. thick, "tied" together with wooden laths at intervals of about 18 inches in height, the space between being filled with small pieces of brick and stone.

A form of construction frequently found is a shell of 4½-in. brickwork around a stout timber post. You see the brickwork bulging and wonder why a stout-looking pier, perhaps 2½ bricks square and 8 feet in height, should be failing under a comparatively light load. The explanation is that the timber post has decayed at its lowest end and the thin shell of brickwork is unable to carry the superstructure.

Modern Brickwork

Modern brickwork is not without its faults, due principally to the lax manner in which it is supervised and an imperfect knowledge on the part of the specification writer. He will, for instance, require that four courses shall not exceed 12 inches in height, and then select bricks that are very little less than 3 inches in thickness. The consequence is that the bricklayer, to keep to the specification, will put an insufficient bed of mortar in laying the bricks. I have had as much as 3 feet of glazed brickwork at a time taken down because there was absolutely no mortar in any of the beds. And this was on a first-class job, under architects and a clerk of works. Again, when the bricks have a frog, that frog should be upwards when the brick is laid, otherwise the brick beds only on the rim and its bearing area is reduced by one-third. When the bricks have two frogs, one should be "buttered," or filled in before laying.

Unless strictly supervised, the vertical joints are never filled solid. Some mortar is rubbed over the top of the course with the flat of the trowel, which may enter the joints some three-quarters of an inch.

A habit of the bricklayer, after having spread the bed is to work the mortar away from the centre with the point of the trowel. The mortar does not squeeze along and make a solid bed as some people argue. To ensure solid work the beds should be thickly spread and the bricks pressed down into it, frogs up, and the whole course grouted up by heaping mortar on the wall and softening it with water from a "gauge pot" so that it becomes soft enough to flow into the vertical joints until they are full.

Unless the beds and joints are full you cannot expect to get the full value out of your walls and piers, which, by the way, are always eccentrically loaded. The evil is aggravated when the wall is faced with stone, for the mason generally spreads a bed of putty, 3 or 4 inches wide, along the outer edges of the stone he is laying (which may be 14 or 18 inches on bed), points up the back edge, and after having poured some grout down the vertical joints, considers he has made a solid job! Have the stone taken up again and note the result.

Workmanship of this sort leads to "flushing" and the fall of pieces of stone. The bed of every course of masonry should be screeded.

Many people object to slate damp-proof courses, as they become inefficient owing to the slate cracking. They only crack or crush when they have been imperfectly bedded. The usual way is to lay them on a bed of cement(perhaps containing a number of small stones) and tap them down with the trowel. This always results in the centre of the slate being unbedded. Walk along such a damp course on your heels, and you will demonstrate to the builder in a striking manner the hollowness of his work.

Use cement made with a sand that contains no small stones, rub each slate well into its bed, and you will get a damp-proof—not a damp—course.

I am not partial to asphalt damp-proof courses unless they are of genuine asphalt. Artificial asphalts are brittle when cold, but become soft in the heat of summer or near a heating chamber, and squeeze out. This allows settlement, and in the case of a retaining or other wall with a lateral thrust to sustain, may allow sliding on the bed, a result which happened not very long ago "somewhere in the Midlands."

Dangerous Concrete

Failures have occurred by using unsuitable materials in the composition of concrete.

There was the case of the reservoir where blast furnace slag was used as the aggregate for its concrete walls. The water affected the concrete so that it became quite soft and rotten, and the walls had to be rebuilt.

Concrete made with breeze is a dangerous material. It is one of the materials specified in the London Building Acts as a fire-resisting material, and as a district surveyor I have, much against my better knowledge, to pass it. This stuff was used for the floors of sculleries in the first storeys of a row of houses built under my official supervision. In every house this stuff expanded, pushing out the walls, some of which had to be rebuilt.

In another district I had to inspect a block of residential flats, the walls of which were bulged at every floor level, owing to the expansion of the breeze concrete.

Loading of Bressummers

It is convenient at this point to refer to the loading of bressummers. Text-books state that when an imperforate wall is built upon a beam the load on that beam may, owing to the bond of the brickwork, be assumed as the weight of the brickwork enclosed by an equilateral triangle which has the clear span for its base.

It is dangerous to make this assumption, for it cannot hold good unless the bond is practically perfect, and all the vertical joints filled solid with cement. Unless you watch every brick, the work is not done in this manner, but as I have already described.

And I would ask, if by the bond all the load of brickwork above the equilateral triangle can be transferred direct to the supports, why should not any portion of the load near the supports or any concentrated load actually over the supports be distributed over and towards the centre of the span?

The method of building a wall brick by brick with soft mortar ensures, I think, that the whole of the masonry over the spans is borne by the beam, and this view is borne out by a case with which I have recently dealt.

Wooden storey posts supporting bressummers decay at the ground line, and are a fruitful source of dangerous structures, as a rule easily dealt with.

You are all familiar with the small suburban house of two or three storeys in which one-half of the weight of the roof and floors is imposed upon a central partition of slender timbers lathed and plastered. The timbers of this partition in the lowest storey are sometimes found to be in a state of decay owing to the want of a damp-proof course. Rotting at the feet, they allow the floors and roof to sag towards the centre of the building and tend to push out the walls.

By-laws which permit the most heavily loaded portion of the building to be constructed with 2 x 4 in. or 2 x 3 in. battens are seriously defective.

Ends of beams and roof trusses solidly built into walls sooner or later decay, and cause dangerous floors and roofs. Ventilation is a sine qua non wherever timber is used. A roof boarded, felted, and covered with slate or metal and ceiled will develop dry rot.

Foundations

The term "foundation" is sometimes used in a very indefinite manner, and may mean the actual base upon which the superstructure is reared or the soil itself.

It has been suggested that the proper meaning of the word is the artificial arrangement or construction prepared or made to support the base of a superstructure; whilst the soil beneath should be termed the foundation bed.

Foundations are important, as when defective or insufficient they will lead sooner or later to a dangerous structure.

In dealing with structures rendered dangerous by settlement owing to the insufficient bearing capacity of the soil, I prefer, wherever there is an underlying stratum of firm material, to sink down to it, even though it should be at a considerable depth. The sinking should be in the form of pits (the area of which would be determined by the loading and the bearing capacity of the firm material), filled up with good mass concrete. Then from pier to pier either construct beams of reinforced concrete or fix rolled steel joists encased in a rich and well-graded concrete or turn arches.

I am not an advocate of raft foundations, for unless your structure can be symmetrically disposed about the raft or its centre of gravity be made to coincide therewith—a very difficult thing to do except in a symmetrical building—the pressure on the soil will be unequal, the raft will tilt and throw your structure out of the perpendicular. The same thing will happen if the soft soil is not of even consistency and bearing value all over.

Trenches

Digging trenches for drains and sewers without sufficient timbering has been a fruitful source of dangerous structures.

(Continued on page 412)

Vertical and Horizontal Reinforcing of Concrete Columns

Considerable has been written from a technical point of view on the strength of reinforced concrete members, as governed by the systematic placing of the reinforcing bars in such positions as to give the maximum strength to the members. Mr. A. M. Wolf, C.E., writing in the Cement World, gives a few notes on placing reinforcing in concrete columns, from a practical point of view.

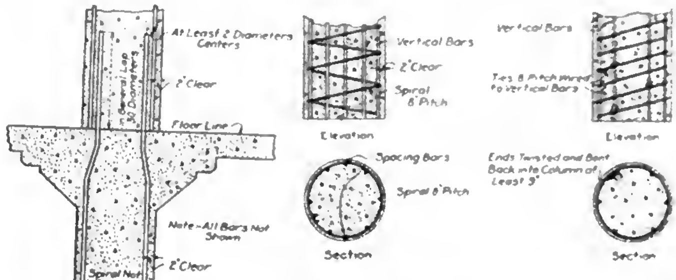
A plain concrete column should not be allowed in any first class building; this does not mean that it should not be used in piers, but for slender columns, those less than 18 inches in least dimension, never. The chances taken with such construction are out of all proportions to the additional cost of a few reinforcing bars, which will at least give the column a factor of safety of more than 1. Experience on actual construction shows that the same care is not exercised in pouring plain concrete as is in the placing of reinforced concrete; and for this reason, if no other, some reinforcement should be used in a bearing member. Even if a column with a ratio of length to least dimension of six with a unit stress of only 200 pounds per square inch is used, it is in the writer's opinion, money well spent to provide longitudinal reinforcement stayed at intervals of not greater than 6 to 12 inches, depending on the size of column or size of bars. In other words, plain concrete columns should be absolutely forbidden, since they have no place in building work. When they are, we will have fewer failures to record.

As for considering eccentric load on plain concrete columns, the writer considers this procedure as flirting with danger. It is perfectly logical and correct to consider this in the development of a discussion on columns, but in the writer's opinion all such discussion should be plainly labeled as theoretical and not practical, since the man who had little experience is not in a position to distinguish the practical limits of theory.

In connection with the design and construction of what are commonly known as longitudinally rodded columns, the writer has found that where such columns are used, that is for carrying light loads as in the upper stories of buildings, and in which the unit stresses are low, i.e., below 500 pounds per square inch on net section, a continuous spiral at a wide pitch is better than a number of loose ties. Such a spiral at 6 to 8-inch pitch by virtue of being continuous, is unquestionably better fitted to stay the longitudinal bars than a number of disconnected, loosely fastened hoops and at the same time requires only a trifle more steel. It also eliminates the difficulty experienced in holding longitudinal bars and the hoops themselves in place. By using two light spaces on such a spiral it can be shipped, "knocked-down," and when expanded, and the spacers set opposite one another, a fairly stiff cage is formed to which the vertical bars can be fastened: this insures proper spacing of bars and hooping which the loose hoop tie method does not. The fabrication cost for such spirals is less than that for hoops at about the same spacing, and the cost of placing the reinforcement is also much less than where hoops are used. Since economy can be effected, and the column materially strengthened by the use of spirals at wide pitch in place of hoops, it seems rather unprogressive to continue the use of the latter, except of course in cases where the vertical bars are placed in the form of a square or rectangle instead of in a circle.

Recent experiences in severe fires have shown conclusively that a covering of 2 inches outside of reinforcing bars cannot be relied upon to stay the latter under such conditions, and engineers are now practically agreed that a rodded column without ties is not good practice. A study of the various reports on the Edison fire will reveal the truth of, and the basis for this statement.

A few words regarding the splicing of column bars at floor levels will probably not be amiss. As for wiring or clamping bar together, to transfer the stress from one to the other in lieu of the longer lap of bars wherein the transference of load is obtained by bond between concrete and steel, it has been shown by tests that such methods of splicing will not develop the proper strength. With both wired and clamped splices where the length of bar lap is cut down to make allowance for the "supposed" efficiency of the splices, it has been found that they cannot be made tight enough to act before considerable slip of bars,



Diagrams show methods of Vertical Reinforcing and Lapping Column Bars at Floor Lines

sufficient to rupture the concrete, has taken place when stress is applied. To the present time no more efficient splice has been found than the simple method of lapping bars a certain number of diameters dependent upon the stresses in same. Such a splice depends on bond between concrete and steel for its strength and it is highly important therefore that the bars are entirely surrounded by concrete, not less than 2 diameters of bar center to center of bars. This means that where columns of the same size and also of different sizes are spliced, the bars from the lower story column should be bent in on easy bends to form a circle well inside the circle formed by the bars above, rather than to have them close together, for where they touch, no bond value can be developed.

Splicing bars by means of pipe sleeves is not done very often at present. Such splices do not tie the different stories of a building together as well as lap splices, nor are the bending stresses likely to be developed in the columns so well provided for, with the use of pipe-sleeve splices. If the sizes of column bars are limited to 1⅛-inch to 1¼-inch bars as a maximum size, splices can be developed without difficulty by bond between lapped ends of bars.

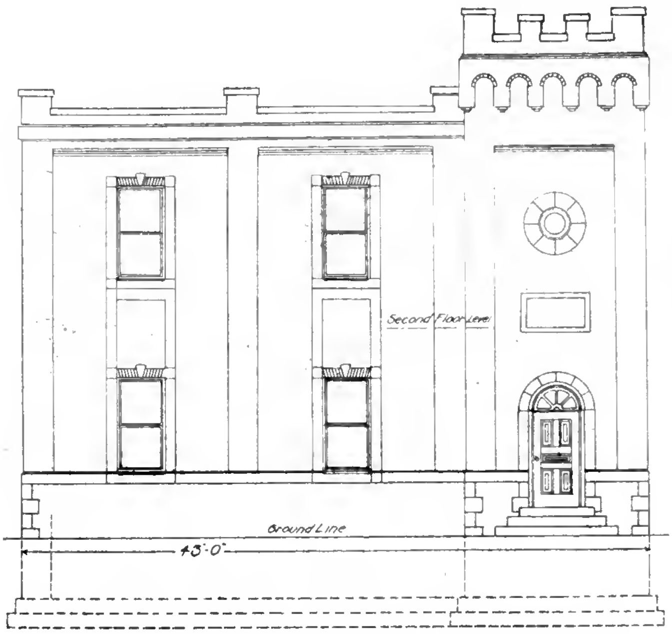
In special cases, as at footings, as combination lap and bearing splice between columns can be used to good advantage, the vertical bars resting on a steel or cast iron ring will transmit some of their load direct by bearing of ring on the concrete, and the remainder by bond between concrete and the stub bars.

Municipal Power and Pumping Station, Sault Ste Marie

THE contract for an electrical sub-station to cost between $10,000 and $15,000 has been awarded by the city of Sault Ste. Marie. When the city assumed the municipal control of the water and light distributing systems in 1914, at which date the franchise of the Tacoma Water and Light Company expired, they entered into an agreement with the Algoma Steel Corporation to supply them with power for lighting, and with the city water-works department to operate the pumping system.

Up to the present the pumping and electrical machinery have been operating in their former location in the power house of the Algoma Steel Corporation. The city, however, decided to build a power and pumping station and to move their equipment into it. Accordingly plans were prepared by their engineer for a building on city property on Gore Street.

The site is an irregular one, being much longer on the front elevation than on the rear. The building is



East Elevation of Municipal Power and Pumping Station, Sault Ste Marie.

consequently irregular also. The building is two storeys, of fireproof construction, brick with stone base and trimmings, with concrete floors and roof.

The lower floor will be taken up largely by two sewerage pump wells with space for future extension. Switchboard and electrical equipment will be placed on the second floor at the North end, where there will also be ample room for extension. The larger part of this floor is partitioned off for use as a meter-testing room for testing water and light meters. The switchboard, which was only recently purchased, is very complete and up-to-date; no new equipment will be installed at present.

The contract for the building has been awarded to I. I. Fitzpatrick, Sault Ste. Marie, and was designed by A. E. Pickering, City Engineer.

The Philip Carey Company, Lockland, Cincinnati, are distributing an attractive booklet entitled "Architects' Specifications for Carey Building Materials." The booklet is splendidly illustrated throughout in colors.

Construction Activity in Berlin, Ont.

The following items indicate the work likely to be carried on in Berlin during the present summer:

Queen Street is to be paved with 6,000 sq. yds. of reinforced concrete; Tarvia pavement with concrete base will be laid on Eby Street and a macadam roadway on South Street; a number of macadam roadways are also to be re-surfaced. Ornamental lighting on Queen Street to Schneider's Creek is under way. A large storm-drain is contemplated through part of Berlin and Waterloo. Sewers will be built on Glasgow Street, Prince Arthur Avenue and Dundas Street. A reinforced concrete bridge is to be built on South Street and also one on Courtland Avenue. The new auxiliary sewage disposal works consisting of pumping station and pumping machinery, sedimentation tanks, spraying filters and humus tanks, were partly constructed last fall and will be complete this year, probably about July. George Moogk, of Weston, is the contractor. The Regal Motor Company intend to build a new factory on South Street. The Onward Manufacturing Company have taken out a permit to build a $10,000 factory on Ahrens Street.

Improvement in Montreal

With the advent of open weather, the construction and supply trades of Montreal are improving. As far as can be seen, no very ambitious building schemes are likely to materialise at present, but a large amount of repair work is being carried out. The permits for last month show only a trifling decrease as compared with the corresponding period of 1915, and this is all the more satisfactory in view of the falling off in the first two months of the current year. Reports from the province are to the effect that a considerable amount of building is in progress, and that the farmers are spending freely on repairs and on new construction.

Have Increased Pumping Capacity

The city of Charlottetown, P.E.I., Water Department has just successfully completed the work of installing a new pump and turbine, having a capacity of 2,000,000 gals. daily, as an addition to the water supply service for the city. Work has been done under the specifications and supervision of R. S. & W. S. Lea, hydraulic and sanitary engineers, Montreal. The machinery was supplied by Fraser and Chalmers, Montreal.

Building Construction and a Few Common Causes of Failures

(Continued from page 410)

Extreme care should be taken when working in bad ground, and the scantlings of the timber should err on the large side, as it is difficult to calculate the pressure to which they will be subjected. If the ground contains water, the pressure may be equal to the extent of the weight of the adjoining buildings. The struts which fix the walings, from the very manner in which they are fixed by driving in, are eccentrically loaded by the earth thrust, and, in my opinion, a system of cross-bracing and vertical ties should be provided to the struts in all deep trenches (of course, at intervals sufficient to leave working room), so that the timbering would not fall to pieces should a movement of earth occur.

Montreal's New Street Lighting System

Cast Iron Standards Fed from Cables in Underground Ducts Embedded in Concrete, Replace Poles and Wires in Business Section

An ornamental lighting system,—the cables for which are installed in the municipal conduits,—has lately been put into operation in Montreal. The streets lighted by the new system are St. Catherine Street, between Atwater and Papineau Avenue, a distance of 2¾ miles, Bleury Street and Park Avenue, between Craig Street and Pine Avenue, a distance of one mile. The system is now being extended down town to include Craig, St. James and Notre Dame Streets and Fortification Lane between Victoria Square and St. Lawrence Street, the square being included. The light is furnished by ornamental inverted magnetite 6.6 ampere arc lamps mounted on cast iron standards of special design.

On St. Catherine Street there are 141 of the new lamps, replacing 57 aerial arcs, while on Bleury Street and Park Avenue 41 of the new lamps replace 18 aerial arcs. These 182 lamps are divided into four circuits, so interconnected in pairs that should one circuit be interrupted some of the lamps on the end of the circuit can be thrown on the other circuit by changing the connection of the four point cutouts in these lamps. The down-town system will have 91 new lamps to replace the 43 aerial arcs now in service. These 91 lamps will be divided into two circuits. The lamps are spaced at an average distance of 125 feet on alternate sides of the street, there being one standard at every intersection and two standards at important intersections and transfer points.

The cable carrying the current to the lamps is No. 6, twin-conductor, paper-insulated, lead-covered, 7500 volt cable, and is installed in a special duct of the Municipal Conduit System which loops in and out of each standard. The cutouts are of the absolute type, and were especially designed to meet the requirements of the Light Department, having four accessible terminals. The location of faults in the cable is thus greatly facilitated, as all four conductors can be exposed in every standard. The leads from the cut-outs to the lamps are No. 6, single conductor, varnished cambric insulated and braided cable. The cables and leads were subjected to a factory test of 20,000 volts for 30 minutes and a test of 10,000 volts for 5 minutes after installation.

The cost of the erection now in operation was approximately $42,000—and the cost of the erection now being installed will be approximately $25,000.

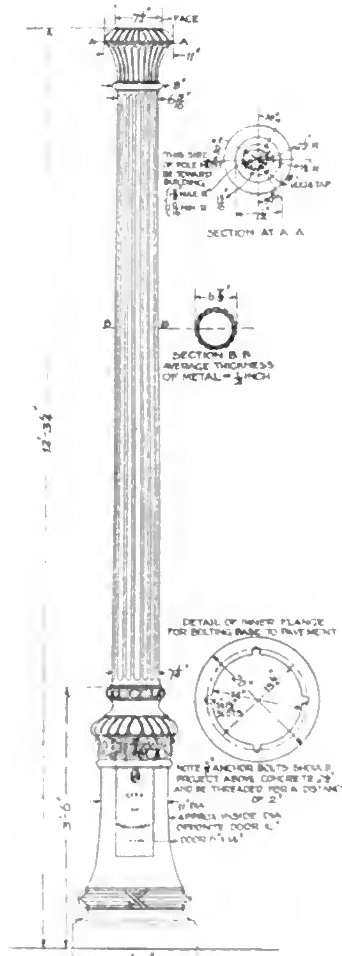
The contracts for the supply and installation of the standards, which included the construction of the concrete bases, were let to G. M. Gest, Limited, of Montreal, Winnipeg and Vancouver, for both sections. The contracts for the supply and installation of the lamps (the glassware for which was manufactured by the Jefferson Glass Company, Limited) were let to the Canadian General Electric Company for both sections, while the order for the supply and installation of the cable and cut-outs was given to the Eugene F. Phillips Electrical Works, Limited, for the system now in operation, and to the Northern Electric Company for the section at present being installed. The cut-outs are manufactured by the Northern Electric Company.

The current for the lamps is supplied by the Montreal Light, Heat & Power Company, under a ten years' contract, at $72.70 per annum per lamp, this price including the supply of station apparatus and the general care and maintenance of the whole system.

The putting into operation of the municipal conduits and the new lighting system on St. Catherine and Bleury Streets, and Park Avenue has enabled the city to remove a considerable part of the unsightly poles and overhead wires from these streets, and the remainder will be removed as soon as conditions permit. The clearing away of this aerial equipment, of which there was a great quantity, has greatly improved the appearance of the streets—especially when seen at night under the brilliant illumination of the new lights. The clean and uncongested appearance of St. Catherine Street as compared with that of former days is especially noticeable.

As soon as the Municipal Conduit System is extended over other districts the new lighting system will also be extended. The districts now under consideration are the section of the city bounded by Commissioners, Notre Dame, McGill and St. Lawrence Streets, and the district comprising St. Lawrence Boulevard from Craig Street to Sherbrooke Street. The work of preparing the estimates, plans and specifications for the new system and the general supervision of the installation was under the direct charge of Mr. Arthur Parent, superintendent of the Light Department, and Mr P. S. Gregory, his assistant.

The removal of the poles and wires above referred to was only possible owing to the construction of underground conduits. In the spring of 1913 tenders were first called by the Electrical Commission for the installation of the conduits. Contractors from many sections bid on this work, G. M. Gest, Limited, being the successful tenderers.



Design of Montreal's new lighting standards

The first installation was made on St. Catherine Street from Guy Street to Papineau Avenue, conduit being placed in the sidewalks on both sides of the street with runs at each intersecting street, while at very important corners these runs were placed at each side of the intersecting street. Later in the same year the ducts were extended on St. Catherine Street from Guy Street to Atwater Avenue, and a system was also installed on Bleury Street from Craig to Sherbrooke Streets, on both sides of the streets, and on Park Avenue from Sherbrooke Street to Pine Avenue, but on the west side of the street only.

The following year the downtown section was constructed on Notre Dame, St. James and Craig Streets from St. Lawrence Boulevard to McGill Street and Victoria Square, including all intersecting streets within these limits, and Fortification Lane. G. M. Gest, Limited, made this installation, as well as that on the two preceding contracts, and in the meantime completed another contract on St. Lawrence Boulevard from Notre Dame, southward.

It was during the construction of the downtown section that the war started, and the work was ordered closed, but through the negotiations of G. M. Gest, Limited, with the city of Montreal, the former carried on their work successfully, thereby giving employment to many men.

In all the conduit contracts the same general type of construction has been used. Three and one-half square bore

15 duct run showing concrete encasement.

tile duct has been used for all light and power cables, excepting that for the services into the buildings, which are of 3½-in. fibre. The top ducts for the police and fire alarm signal wires, street lighting, Gresham Guarantee Company, are 3½-in. fibre, and are separated by a concrete fill from the balance of the system. The ducts are all enclosed in a three-inch concrete encasement, and graded to drain through the manholes at each end.

Main and service manholes are of concrete of octagonal shape, the 6 ft. x 8 ft. holes occurring at street intersections, with service holes 4 ft. x 6 ft. located between street corners, providing for services into all buildings. Each hole is drained through a trap and connected to the street sewer, thereby affording perfect drainage through the whole system. Ventilated covers are provided and these are of such design as to give sufficient strength without being unduly heavy.

Each of the operating power companies is provided with its own transformer manholes, which in general are about 10 ft. x 12 ft. with 8 ft. headroom. These are located in the side streets and are connected with the main manholes by fibre pipes. They have covers made in three sections of ample size to admit of transformers being placed. These holes are also of concrete and are connected to the sewer through a trap.

Owing to sub-surface conditions of many of the streets,

St. Catherine Street, Montreal.

it seemed at times almost impossible to place some of the intersecting runs and manholes, as the streets were already filled with the sewer, gas and water pipes on each side, the duct systems of the Montreal Light, Heat & Power Company, and the Bell Telephone Company. However, the past experience of the conduit contractors was of great service in overcoming these obstacles, and in no instance was it found impossible to make an installation as required.

The Bleury Street and Park Avenue section differed from that of the other streets in that a portion of the system was made jointly with the Bell Telephone Company, having separate ducts and manholes. These joint holes had a common wall, but with enough offset on each side to allow ducts to take care of the distribution in intersecting streets.

The telephone ducts are of multiple tile, and at all points are separated from the power ducts by at least six inches of concrete and gradually fanning out to reach the manholes. In addition to the power company having cables in the municipal ducts, the street lighting occupies a duct as also the fire alarm system. Ample space is provided so that future electrical needs can be taken care of without undue crowding.

It is the plan of the Electrical Commission to gradually extend the conduit system over the entire city of Montreal, removing all overhead wires and poles, thereby making Montreal entirely free from delay and danger to which it had been subjected in the past.

Ninety-one members of the Corporation of B. C. Land Surveyors have become members of overseas forces since war broke out. Four have been killed in action, four have been wounded, and two are prisoners in Germany. Among the wounded is Lieut. P. D. Booth, Royal Field Artillery, who has been awarded the military cross for bravery at the Dardanelles.

Regulations Respecting Highways

Ontario Department Issues Rules for the Guidance of Road Superintendents and Engineers in County Road Construction and Repairs

The following are the Regulations of the Department of Public Highways with respect to county road construction, maintenance and repair under The Highway Improvement Act and The Ontario Highways Act, upon compliance with which the county becomes entitled to the Provincial subsidy payable under the said Act:—

County Supervision and Records

1. The management of all road improvement, maintenance and repair is to be centralized in a capable county road superintendent appointed by and acting under the direction of the county council. A foreman is to be placed by the superintendent in charge of any works which he cannot personally oversee.

2. An approved system of keeping road accounts is to be adopted showing the extent and location of each work of improvement, and the cost of labor and materials used. Expenditures for maintenance and repair are to be kept separate and distinct from construction costs. Time sheets and time books are to be used for the payment of men. Such returns, reports and statements respecting all details of work, methods and expenditure, are to be supplied to the Department of Public Highways as may from time to time be required. Blank forms for annual returns will be supplied to superintendents or other officials upon request.

Departmental Returns

3. Returns to the Department of Public Highways are to show definitely, according to township, lot and concession, the location and terminal points of the work done; thereafter, similar work of construction for that road is not to be a charge upon the Province. Each section of road is to be fully completed at one time unless circumstances do not permit. A repeated charge for any class of work, such as draining, grading, metalling, etc., will not be allowed as construction; but when reported complete by the superintendent is to be regarded as finally completed for that class of work on the defined section of road.

4. Statements of annual expenditure are to close on December 31st of each year, and are to be transmitted to the Department of Public Highways as soon thereafter as circumstances will permit.

GENERAL CONSTRUCTION

5. Improvements are to be of a character suited to the requirements of the district as regards the amount of travel, nature of the soil, quality of road metal available, and other local conditions.

6. Construction is to be guided by the last revised "Handbook of Roadmaking" issued by the Deputy Minister of Highways, except as more specifically stated in these regulations.

7. Work on old gravel or stone roads of the nature of reconstruction or repair may consist of:—

(a) Grading by cutting away shoulders of earth and sod at the sides, and improvement of drainage.

(b) Grading, draining and metalling with good gravel or broken stone, or other approved surface material.

8. Work on new roads may consist of:—

(a) Grading and draining.

(b) Grading, draining and metalling with good gravel or broken stone, or other approved surface material.

9. General construction is to be in continuous stretches of not less than one mile in length. Unless for unavoidable reasons, work done on shorter sections will be rated as maintenance.

10. The road allowance, before construction is undertaken, is to have a minimum width of 66 feet between fences.

Grading and Earthwork

11. It is essential that all roads be permanently graded and earthwork completed before putting on gravel, broken stone or other surface material. Old gravel and stone roadbeds are not to be unnecessarily injured or destroyed by being covered with earth and sods from the sides. (Vide section 26). Roads are to be given easy, flowing, uniform grades, cutting down hills and knolls, and filling depressions. The standard grade shall be 4 per cent., but a maximum rise of 8 per cent. may be permitted by the Department. Thorough grading is insisted upon.

12. The roadway graded for traffic is to be as straight as practicable, and in the centre of the road allowance, with a uniform width between the inside edges of the open ditches, and the superintendent shall see that work is carefully staked out for this purpose in advance of draining, grading and metalling.

13. The width of the graded roadway, shoulder to shoulder between ditches, should not be less than 18 feet for least travelled single-track roads; and roads of heavier traffic should be graded to a width of 24 feet if for single-track and 27 feet if for double-track.

14. Side slopes are to be suited to the natural stability of the soil, but are to be not less than one and one-half feet horizontal to one foot vertical.

Finished Camber or Crown

15. The crown or camber given the newly graded and consolidated roadway is to be uniform, and on single-track roads is to have a rise of one inch to the foot from the shoulder of the ditch to the centre of the road. On double-track roads metalled with broken stone and thoroughly consolidated by rolling, a crown of one-half inch to the foot will be sufficient. Special care is to be given to the crown at or near the top of hills and at the foot. The crown on hills is to be sufficient to turn the water to the gutters and prevent it from following the wheel tracks. In resurfacing old gravel and stone roads, the camber of the consolidated surface should be not less than one-half inch to the foot.

Foundation

16. Stone and gravel roads should have an adequate foundation adapted to the strength of subsoil and the probable weight and frequency of traffic; the upper four inches of consolidated material to be regarded as the wearing surface, and the remainder of the road crust, with the subsoil, to be considered as the foundation.

Gravel and Broken Stone

17. Road metal (gravel and broken stone) is to be placed in the centre of the grade to a width and depth sufficient to form a serviceable road, having due regard to the character and extent of traffic. Single-track roads shall preferably be metalled to a width of ten feet, and double-track roads to a width of eighteen feet.

18. The gravel or stone spread on the road should not be of a less width than eight feet, nor of a less depth than eight inches.

19. The gravel or broken stone used on the road should

preferably be obtained in the vicinity of the road, but must be of good quality.

20. The stone used may be broken field stone, quarry stone, crushed and screened gravel or natural gravel of good quality, care being taken to select a durable quality such as will withstand wear and exposure to the atmosphere, discarding weathered limestone, friable sandstone, or other weak metal.

21. Gravel is to be clean, moderately coarse and free from an excess of clay, sand or earthy material.

22. In applying natural pit gravel containing many large stones, the large stones are to be raked forward from the loose gravel, spreading them so as to be underneath the next load and in the bottom of the road.

23. The gravel or broken stone placed on main roads is to be thoroughly rolled. Roads of less importance, if not rolled, are to be maintained by raking, or trimming with a grader until consolidated by traffic. Each county shall have at least one steam roller.

24. Stone when crushed is to be elevated into bins, from which it can be conveniently and quickly loaded into wagons.

25. Clay, sod or other earthy material is not to be used as a surface dressing or binder on broken stone roads. Stone screenings are to be used for this purpose. Care is to be taken that an excess of this surface dressing is not used.

26. Where roads have heretofore had gravel or broken stone placed on them, they should be reconstructed or repaired by cutting off shoulders with a grader and adding a sufficient amount of gravel or broken stone to fill ruts, depressions, properly crown and make a road sufficiently strong to accommodate the travel. The sod and soft material is to be thrown outward, never drawn to the centre.

Drainage

27. Good drainage is of primary importance. Open drains are to be provided at both sides of the road, with a constant fall to a free outlet, and with sufficient capacity to carry away surface water.

28. Tile under drains are to be laid to carry away excessive subsoil water, lower the water-line, and secure a dry roadbed wherever a moist, damp or springy condition of the subsoil exists.

Bridges and Culverts

29. Durable sluices and culverts are to be built when necessary. Bridges must be substantial in character, preferably of concrete or steel.

30. Bridges are to comply with the approved specifications of the Department of Public Highways; all forms of tender, specifications, and the work throughout, are to be in charge of an engineer qualified to see that such specifications for steel and concrete bridges are carried out. Wherever practicable, bridges are to be built by contract, for which tenders shall be received after due public notice has been given.

Machinery and Miscellaneous

31. Modern roadmaking machinery, equipment, implements and plant are to be used so as to secure the greatest results from the expenditure, and to do the best work. Machinery and other equipment is to be sufficient only for proper construction, maintenance and repair, and authority to purchase is subject to approval.

32. Work is to be carried on in such manner and at such rate as will ensure completion of the designated system of roads without unnecessary delay and within a reasonable period, consistant with the local extent and cost of construction.

33. When in any county the roads assumed as county roads are not of equal importance, they may be classified, and the nature and extent of improvement to be carried out on each class designated by the Department of Public Highways. Provincial liability shall thereafter be limited to the cost of improvement so designated.

34. All plans of road construction, systems and means of carrying on the work, contracts and specifications pertaining thereto, are to be such as will produce durable construction with economy of outlay, and are to be submitted for and shall be subject to approval.

35. Whenever a concrete, brick, bituminous, wooden block, stone block, or other durable type of surface is considered desirable by the county authorities, rather than a water-bound broken stone or gravel roadway, specific approval must be obtained for such construction, together with approval of plans and specifications.

MAINTENANCE AND REPAIR

Repair

36. For small repairs the county shall employ patrolmen to take charge of definite sections of all heavily travelled roads. The length of each section may vary with traffic and general requirements of the road, as experience may determine, but the number of men so employed, and the section allotted to each, shall be such that the system of roads will be kept in an efficient state of repair.

37. Patrolmen may work singly or in pairs as the superintendent may direct, and shall be subject solely to the instructions of the superintendent.

38. Patrolmen employed by the county are to be industrious, honest, sober, and of practical ability so that they will give full value in service for every dollar received. Failure in these particulars is to be met by dismissal by the superintendent.

Duties of Patrolmen

39. For purposes of repair, suitable gravel and stone will be supplied by the county, preferably in piles along the roadside, for use of the patrolmen.

40. For the repair of depressions, holes and wheel tracks, stone of the largest size possible is to be used, up to 2-inch gauge, and stone dust and chips are to be used for binding. The use of clay, loam, sods or earthy material of any kind is prohibited.

41. Holes and depressions in the road surface are to be filled promptly, using the same material as was employed for construction, viz.: gravel for gravel roads, and broken stone for stone roads.

42. Ruts and holes should be so filled that there will be neither a lump nor a depression when the new material is consolidated.

43. Deep holes in gravel and stone roads should have earth and soft material cleaned out of them before filling with new metal.

44. Loose stones are to be raked from the surface of the road, collected in piles, and thereafter used in the improvement of the road.

45. Sod, loam or earthy material is under no circumstances to be drawn from the shoulders to the surface or centre of a stone or gravel road.

46. When it is necessary to place loose gravel or stone on a road (without rolling) the wheel tracks are to be raked full from time to time until the road surface has been consolidated by traffic.

47. Ditches and drains are to be kept clean and free from obstruction.

48. Attention is to be given at all times not merely to keeping the existing drains in the condition following construction, but to improving such drains wherever practicable so that water will not remain in depressions on the road or roadside.

49. Special care is to be taken that the shoulders of the road are kept smooth and free from weeds so that surface drainage is not impeded.

50. Snow and ice are to be removed from the ends of

drains and culverts, and drainage outlets are at all times to be carefully watched to see that they are not obstructed by leaves, weeds, silt or other material.

51. Brush and noxious weeds are to be cut and burned, or otherwise removed from the roadside.

52. Brush is to be cut at all cross-roads, bridges, railway crossings, curves or other points of danger.

53. Floors of bridges and culverts, the approaches to bridges and culverts, and all guard rails are to be kept in repair by the patrolman.

54. The patrolman is to promptly provide protection in case of washouts or other emergency, and to place red lights, notifying the superintendent immediately of any such conditions.

55. Unauthorized signs erected within the road allowance are to be removed if so directed by the county road superintendent.

56. The patrolman for water-bound macadam or gravel roads is to supply a horse and light wagon (or cart), and is to have a shovel, rake, scythe, pick, heavy broom, tamper, and such other tools as he may from time to time require. Where tar or heavy oil is used, the foregoing are to be supplemented with the necessary equipment in accordance with the quality of material used.

57. The patrolman will be held responsible for tools provided by the county, which are to be kept suitably protected and in proper repair.

58. Snowdrifts are to be shovelled out by the patrolman, and when help is needed to do this work promptly, he should engage the necessary assistance.

59. The patrolman should keep a time-book showing time employed on the road, and nature, location and amount of work performed. The time-book should be mailed or sent each week to the superintendent (and by having two such books they can be used for alternate weeks).

Maintenance

60. The maintenance of roads (as distinguished from small repairs) and including re-surfacing, oiling, widening or other improvement authorized by the Department, is to be adequately and promptly carried out by the county, so that unnecessary injury will not result to the road from neglect.

61. The work of maintenance is to be performed under the general organization and regulations provided for first construction in so far as applicable, the county preferably to have one outfit under a foreman, with suitable tools, equipment and workmen, continuously engaged on such maintenance, or construction and maintenance, during the working season.

62. Earth roads prior to metalling may be maintained by the systematic use of the grader and drag.

63. Work of repair, such as the removal of sod shoulders and occasional cleaning of ditches, which can be cheaply done by machinery, is to be done by the maintenance outfit rather than by the patrol system.

Special Local Conditions

64. Where, owing to special local conditions, any departure from the foregoing regulations may be desired, upon application to the council or superintendent to the Deputy Minister of Highways, an examination of the road or roads or circumstances in question will be made by an engineer of the Department for the purpose of deciding with regard thereto.

Interpretation

65. In these regulations relating to construction, maintenance and repair of county roads, "superintendent" shall mean county road superintendent appointed by the county council in accordance with section 7 of the Highway Improvement Act.

66. "Approved" or "approval" shall mean approval by the Deputy Minister of Highways, whose decision as to the scope, intention and interpretation of these regulations, or any part thereof, is to be final.

67. "Old" roads include such highways as have been previously well graded and metalled with gravel or broken stone, and which have a solid and deep roadbed. Former toll roads, and roads of a similar character will usually fall within this class.

68. "New" roads in general include earth roads which may or may not have been previously graded, and which have had little or no gravel or stone placed upon them.

69. "Single-track" roads shall be those metalled from 8 to 12 feet wide, and "double-track" roads shall be those metalled more than 12 and up to 18 feet wide.

70. "Repair" shall mean the mending of holes and ruts, the cutting of weeds, the cleaning of ditches and gutters, the raking of loose stones, and such mending as is necessary to keep the road smooth and in good condition for traffic, and to prevent rapid deterioration.

71. "Maintenance" shall relate to the uniform wear of the road under traffic, and the periodic expenditure and work necessary to re-surface and restore the road crust to its original thickness, or may include the widening or strengthening of the road crust made necessary by increased traffic, also oiling or the use of bituminous or other carpet-coat materials to protect the road and prevent dust after first construction.

72. "Department" shall mean the Department of Public Highways of the Province of Ontario.

Trade Inquiries

Names and addresses may be obtained from the Department of Trade and Commerce, Ottawa.

320. Asbestos cement sheets—A London firm of engineers are in the market for 250,000 square yards of asbestos cement sheets, 3/16 in. thick, and invite quotations from Canadian manufacturers.

324. Brass steam fittings—A Glasgow firm wishes to obtain the representation of a Canadian house for the above. Satisfactory references.

325. Steel billets and wire rods—A Coatbridge firm asks for Canadian sources of supply.

326. Rolled steel joists; bars of all sections, rivets and bolts. A Glasgow house will be glad to receive catalogues and quotations c.i.f. Glasgow quay.

327. Steel joists—A large Glasgow firm would be pleased to receive quotations for say 150 tons steel joists to the following sections, or nearest procurable sizes: 9 in. by 4 in. by 21 pounds; 8 in. by 4 in. by 18 pounds; 7 in. by 4 in by 16 pounds; 6 in. by 3 in. by 12 pounds; 5 ins. by 3 in. by 11 pounds; all in 40 ft. lengths.

328. Galvanized fencing wire—A Glasgow firm desires to know if galvanized fencing wire can be obtained from Canada. Supplies formerly procured from Belgium.

330. Tinned steel mattress wire—A firm at Liverpool manufacturing wire mattresses would like to receive quotations from Canadian manufacturers of tinned steel mattresses wire in 21½, 22½ and 23 standard wire gauges.

329. Iron or steel bars—A Glasgow firm is open to purchase iron or steel bars notably bulb tee bars 1½ by 1½ equal 2½ pounds per foot, and varillas ¾ in. by ½ in by 8 oz. /ft.

339. Representation—A gentleman in New York who has travelled throughout Asia, the Pacific Islands and Australia for the past seventeen years in the interest of certain United States manufacturers, desires to be put in touch with Canadian manufacturers who are anxious for export trade, since he has had many demands on past trips for goods manufactured in Canada.

In the Public Eye

A budget of comment presented in the interest of public welfare, independent of party politics and with malice toward no one.

After eighteen months of silence "Industrial Canada," the mouthpiece of the Canadian Manufacturers' Association, has joined its voice to those of other journals that could not stomach what went on at Ottawa in connection with the letting of contracts for shells and fuses by the late Shell Committee. "Industrial Canada" tells us in its latest issue a few things it knows about fuse contracts and says that eighteen months ago the Canadian Manufacturers' Association went to the Government and tried to make it realize that the "license to loot" ought to be terminated. Their warnings, like those of many of the Government's political supporters were, according to "Industrial Canada" allowed to pass unheeded. So, at this late date, after giving the matter eighteen months of silent thought, the organ of the Canadian Manufacturers' Association, the members of which are both liberal and conservative, comes into the lime-light with its statement of some of the things that have come under its notice.

* * *

I will outline the story told by "Industrial Canada" a little later on, after I have said what I feel about the part this mouthpiece of the manufacturers has been taking. While the making public of this story is better late than never, I cannot help wondering how such a journal can square itself with its own conscience for having kept silence all these months. It seems to me that this is just another example of the weakness exhibited by 90 per cent. of the journals of Canada in failing to do their plain duty. What is a public journal for, if it is not to tell the public some of the plain facts about its public men, especially when the good name of the country is being soiled? When the testing time comes, many of these journals lack the backbone, or the nerve to speak out. They act the part of Falstaff whose chief maxim was the comfortable idea that "discretion is the better part of valor" and they just keep mum. They wait until the burglar gets away with the swag, and finally, when so much has been filched from the public purse that no one can shut his eyes to it any longer, some of them join in the chase with a great hue and cry.

Why did not "Industrial Canada," in the interests of manufacturers, make its public protest eighteen months ago, when the trail was hot and there was some prospect of getting hold of the culprits before they cleared off with whole skins and a big swag? It was left to this paper—the Contract Record—to make the first protest in the interests of the manufacturers of Canada, and in the interests of clean government and the good name of the people of Canada; and for some time it was left to us also to continue the protest almost alone. The Canadian Manufacturers' Association, through their organ "Industrial Canada," made their protest silently and without effect eighteen months ago. They should have followed this up at that time with a public statement, instead of waiting for eighteen months and watching the continuation of those evils about which they told the government in a whisper.

I do not relish the idea of saying much about my own doings, but I may be excused for pointing out such shortcomings on the part of other journals, and saying, that in spite of my own loneliness all these months, I have felt, and still feel, that I have been doing the Canadian manufacturers and the Canadian public a real service in laying bare some of these ugly truths; a service which the public had a right to expect, the manufacturers especially, from those other journals, and more especially from their own industrial mouthpiece.

* * *

Here is the story of "Industrial Canada," told as briefly as we can put it:—Eighteen months ago the Canadian Manufacturers' Association approached the Government and told them some of the things they knew about the way in which fuse contracts were being given to Americans and refused to Canadians, and what people were saying about it all. "The reception given these suggestions, says Industrial Canada, "was not of a character calculated to invite further co-operation."

"There are limits," Industrial Canada continues, "to the patience of loyal citizens even in war time, and much as we may deplore the disgrace that the fuse scandal has brought publicly home to Canada, and warmly as we may resent the effort to make political capital out of it at a time when our national energies ought all to be centred on winning the war, there is no getting away from the fact that the situation was intolerable, and that the license to loot had to be terminated."

After a little more in the way of an introduction, the article continues, saying that Mr. T. A. Russell and Mr. Lloyd Harris, of the Russell Motor Car Company, Limited, heard in April, 1915, that fuse contracts had been "going begging," since November, 1914. Their first information about it was received in New York from Sir Sam Hughes, who, by personal introduction referred them to Col. Allison in the Manhattan Hotel for details. Preferring to do business direct with the Shell Committee, Messrs. Russell and Harris went to Montreal and made overtures to the Committee through Gen. Bertram and Col. Carnegie." The upshot of this business was that they were again referred to Col. Allison, "who was said to have the matter in hand for prospective contractors in the United States." After considerable perseverance and general rebuffs, Messrs. Russell and Harris "were given a promise that one million of the five million fuses required would be held, pending the receipt of a tender from them, providing that tenders were submitted within a reasonable time." A reasonable time in their case "was defined as two weeks, notwithstanding the fact that Allison had presumably been busy on the proposition for five months without being able to offer anything definite."

Within the two weeks Messrs. Russell and Harris notified the Shell Committee that their proposition would be ready on the date specified. "And now for the fact that requires explanation," continues the article in Industrial Canada. "On May 25th, 1915, the Russell tender was turned in, offering to make 1,000,000 fuses at $4.20. On May 19, without waiting for this competitive tender, which was known to be on the way, and regardless of the promise given to hold at least a portion of the business open, the committee awarded contracts for the whole of the 5,000,000 fuses to the companies promoted by Allison and his associates, a small fraction of them at $4.00, but the majority of them at $4.50. The loss in money is a matter of easy calculation from the records of the committee. The loss in time of delivery is also determinable, because whereas the United States contractors have fallen far behind with their obligations, the Russell Motor Company are now delivering ahead of time under a contract they subsequently secured at $3.70. The indirect loss to Canada and to the Empire through the sacrifice of domestic to foreign enterprise is beyond computation."

* * *

It is unnecessary to comment on this story at present.

It simply adds a chapter to many that I have already published. Nor is it necessary to say much about the characters of the parties who are referred to as taking part in it. The fact that one of these parties is Mr. Lloyd Harris, stamps the story as deserving of every confidence. Mr. Lloyd Harris is one of the brightest and cleanest men we have in Canada today, and there are a good many others of his type. The thing that I cannot quite understand is why he, or others of his calibre, were not employed by the government in this crisis. Can it be that he was too big a man for them? Whatever reply you give to this question, the Dominion Cabinet needs a good cleaning out, if the conservative party is to be saved from defeat.

* * *

Just by way of an example of the above idea, I may mention the case of Hon. A. E. Kemp, the chairman of the Purchasing Commission, who also has been acting Minister of Militia during the absence of Sir Sam Hughes. Is it in the interests of the people that a man who is so interested in companies selling goods to the Government should be occupying an important position on a Purchasing Commission? Is there not even a sufficiently vigorous public opinion in Canada to teach such men that their positions as members of Parliament are positions of trust, to be exercised for the public welfare, not positions of profit to be utilized in their own interests? Does it not make you question whether the men who get to the top of the tree in our political life are men of the large calibre they should be? In the name of Heaven, are there no big men in this country who could handle our affairs more after the manner in which we have every right to expect they should be handled?

SEARCHLIGHT.

Personal

Mr. William G. Murdoch, city engineer of St. John, N.B., delivered an instructive address to the engineering students of the University of New Brunswick on the 17th inst., his subject being the Suspension Bridge.

Mr. J. Quail, formerly sales engineer for the Manitoba Bridge and Iron Works, has accepted the position of manager of the western office of the Canadian Bridge Company, of Walkerville, Ont. His office will be in the Garry Building, Winnipeg.

Mr. H. V. Keating, civil engineer, Fort Frances, Ont., has charge of the construction of a large paper mill for Warren Curtis, of Thorold, Ont., to be built about sixteen miles from Shelter Bay, on the lower St. Lawrence, below the island of Anticosti.

Mr. E. J. Lennox, a Toronto architect, has received a judgment for $1,309 against the Russell Motor Company. Five years ago Mr. Lennox was entrusted to prepare plans for a factory for the defendant company, and the action was for recovery of money due on the work.

Mr. W. H. Fairchild, the newly-appointed city engineer of Galt, Ont., has had a long and varied experience in his profession. He is a native of Brant county, and started his engineering career in 1895 with City Engineer Jones of Brantford. After four years' training he moved to Simcoe, where he engaged in private practice and received the appointment of engineer for the counties of Norfolk and Haldimand. In 1907 he returned to Brantford, and controlled practically all the engineering outside the city of Brantford in the counties of Brant, Norfolk, and Haldimand. In 1913 Mr. Fairchild went to Vancouver, where he had charge of the Pacific Coast Freight Buildings for the C. N. R. On the outbreak of war, work ceasing on this job, he went back to Brantford, where he practised his profession until appointed city engineer of Galt.

Mainly Constructional

Owing, it is said, to lack of competition, the price of cement in Calgary is 23 cents higher than in Edmonton.

The town of Dundas, Ont., are considering the installation of a sewerage system, and have engaged Messrs. Murray & Lowes to prepare plans and estimates.

Work that will run up to a quarter of a million dollars is in sight already in South London, Ont., and a very busy season in the building line is expected. A large number of splendid residences are being erected.

The Ohio State Highway Department has made the first important awards of the season of state highways work. The amount of the contracts exceeds $1,250,000 and the work covers more than 90 miles of roads in many counties.

The property of the Nova Scotia Car Works, Limited, Halifax, N. S., is to be sold for the benefit of creditors. The company's liabilities amount to $347,000. It is understood that the Nova Scotia Steel and Iron Company are desirous of securing the property.

It is now said that the Nova Scotia Steel and Coal Company are about to embark upon the steel ship-building industry, and that this was the reason for the increased capitalization of the company which was authorized at the annual meeting a few weeks ago.

Thomas Kelly, the Winnipeg contractor, has lost his fight against extradition in the Supreme Court at Washington, and will have to return to Winnipeg to face a charge of having obtained $1,250,000 by false pretences in connection with the Parliament Buildings contract.

The Blystone Manufacturing Company, of Cambridge Springs, Mass., are considering the erection of a factory shortly in Niagara Falls, Ont., on a site purchased by the company a year ago. The company manufacture concrete mixing machinery, and the Niagara Falls plant will be used as an assembling department of the main factory in Philadelphia.

Mr. E. W. Bowness, of the Edmonton Power Company, is on his way to England, where he will consult with the head office of Sir John Jackson, Limited, regarding the city's power scheme. Mr. Bowness states that on his return, some time in May, the work on the railway end of the project from Edmonton to Blue Rapids will be commenced immediately.

Bradstreets report that building permits for ten Canadian cities in March numbered 339, with a total value of $745,515, this being a decrease of 52.3 in the number, but an increase of 6.4 in value. For the first quarter of 1916 permits totalled 660, with a value of $1,367,219, a decrease of 48.7 in number and of 26.5 in value. At the same time 149 United States cities showed a decrease of 20.2 per cent. in value.

The city of Edmonton has constructed at the foot of 101st Street on Ross Flats a sewage disposal plant at a cost of $50,000. The plant is being completed along experimental lines, and thus serves the double purpose of treating part of the city's sewage and acting as a guide in the design of larger plants which will be constructed later. The new activated sludge process of sewage purification is being tried.

Mr. M. H. MacLeod, general manager of the Canadian Northern Railway, has completed arrangements for the west coast terminal facilities of the railway, and a million-dollar station at Vancouver will be commenced in a few weeks. The station will provide for development of the railway, being planned to meet all possible requirements for many years. In addition to this, the company are undertaking a car ferry service from Vancouver to Vancouver Island, part of which will be in operation next month.

The Dickson Building Company, King Street, have commenced the erection of a factory on Hatt Street. Brick construction.

Harry Cohen, King Street, is now receiving tenders on the erection of a store and residence, estimated to cost $6,000. Brick and concrete construction. Architects, Ellis & Osborne, Dundas and Toronto, Ont.

Edmonton, Alta.
The Western Mausoleum Company, Limited, Boyd Building, Winnipeg, propose to build a mausoleum at an approximate cost of $400,000. Work may start this summer. Granite construction, marble interior.

Galt, Ont.
Dr. J. A. McDonald has decided to rebuild the Imperial Hotel, and will have plans prepared.

Hamilton, Ont.
The Grasselli Chemical Company have prepared plans for an addition to their factory, estimated to cost $30,000. Brick and corrugated iron construction.

Kentville, N.S.
Perry Bishop is about to build a business block by day labor under supervision of Arthur B. Ward. Frame construction. Estimated cost, $6,000.

Kingsville, Ont.
The Erie Tobacco Company intend to rebuild their premises, which were recently destroyed by fire. Manager, Oliver Fox.

London, Ont.
Tenders will be called early in may for the erection of a warehouse for Webster & Harvey, Richmond and Oxford Streets, for which plans are being prepared by J. M. Moore, 415 Richmond Street. Approximate cost, $12,000.

Markham, Ont.
The Markham Agricultural Society will receive tenders until May 12th for the erection of a building suitable for an agricultural hall and rink. Particulars at offices of James Malcolm.

Montreal, Que.
W. A. Mahoney, Telephone Building, Guelph, Ont., is preparing plans for an addition to the premises of the Canada Stove Company.

New Westminster, B.C.
The City Council will shortly call for tenders on the erection of a market building on Lytton Square. Concrete construction. Approximate cost, $30,000.

Ottawa, Ont.
The Imperial Motor Company, 150 Albert Street, propose to erect an addition to their premises.

Quebec, Que.
Work has been started by day labor on the conversion of a store into a theatre for Delphis Brochu, 63 St. John Street. Estimated cost, $6,000. Architects, Tanguay & Lebon, 20 d'Aguillon Street.

Saskatoon, Sask.
Plans have been prepared for an incinerator to be built for the City Council. It is probable that the contract let in 1914 to Laurie & Lamb, Montreal, will be cancelled and new tenders called. Approximate cost, $100,000. Engineer, G. D. Archibald.

Toronto, Ont.
The Campbell Flour Mills Company, Limited, are considering the erection of a storehouse and cooperage, at an approximate cost of $5,000. Work will include the wrecking of existing buildings.

The Brandon Company, 108 Vine St., have had plans prepared for a machine shop to cost about $5,000. Steel and brick construction.

Whitby, Ont.
The erection of two stores on Brock Street is being considered by W. J. H. Richardson and the Misses Richardson. Brick construction. Approximate cost, $5,000.

Whitebread, Ont.
R. Stenton, Wallaceburg, is about to start work on the erection of a barn, estimated to cost $3,000. Frame and concrete construction.

Windsor, Ont.
Plans of stores and apartments to be built for H. Benstein, 54 Pitt Street E., are being prepared by G. Jacques, Boug Block. Tenders will be received from May 6th to 15th. Brick and concrete construction. Estimated cost, $18,000.

Yarmouth Township, Ont.
J. B. Turner, Edgeware Road, St. Thomas, proposes to rebuild his barns, recently destroyed by fire. Fireproof construction. Approximate cost, $3,500.

CONTRACTS AWARDED

Fenelon Falls, Ont.
The general contract for the erection of three stores for James Fraser has been let to A. McLeod, 57 Benlamond Avenue. Smaller trades will be sub-let. Concrete block construction. Estimated cost, $4,000.

Halifax, N.S.
The general contract for the erection of a machine shop for the Halifax Graving Dock Company, Granville Street, has been awarded to G. M. Brookfield Ltd., Granville Street, and the electrical work to Farquhar Brothers, Barrington Street. Approximate cost, $16,000. Reinforced concrete construction.

Hamilton, Ont.
George Hill, 21 Vine Street, is building a stable, estimated to cost $6,000, and has let the contract for masonry to H. Jones, 29 Macaulay Street E. Contracts will also be let for steel work and roofing.

The contract for the construction of

(Continued on page 47)

Tenders and For Sale Department

To Contractors

Sealed tenders will be received up till noon, **April 26th, 1916**, by the Secretary, for the erection and completion of a six-roomed Public School Building for Finch School Board Section No. 3, in the Village of Finch, Ont.

Drawings and specifications can be seen at the undersigned. The Board reserves the right to reject any or all tenders. The successful tenderer will be required to furnish satisfactory guarantee as to good faith. Tenders will be opened after 8.30 o'clock p.m. May 1st.

GEO. S. CASSELMAN,
16-17 Secretary.

Construction of Cribwork and Concrete Wall

Sealed tenders will be received up to 12 o'clock noon, **Monday, May 1st, 1916**, addressed to the Chairman of the Toronto Harbor Commissioners, 50 Bay Street, Toronto, Ont., and marked "Tenders for Harbor Head Walls."

All information may be obtained by applying to the above address. Tenders received after the time above named will not be considered.

The Commissioners reserve the right to reject any or all tenders received.

E. L. COUSINS,
16-17 Chief Engineer and Manager.

Tenders for Dredging

SEALED TENDERS addressed to the undersigned, and endorsed "Tender for Dredging, Port Hope, Ont.," will be received until 4.00 P. M., Tuesday, May 2, 1916, for dredging required at Port Hope, Ontario.

Tenders will not be considered unless made on the forms supplied, and signed with the actual signatures of tenderers.

Combined specifications and form of tender can be obtained on application to the Secretary, Department of Public Works, Ottawa. Tenders must include the towing of the plant to and from the work.

The dredges and other plant which are intended to be employed on this work shall have been duly registered in Canada at the time of the filing of this tender with the Department, or shall have been built in Canada after the filing of the tender.

Contractors must be ready to begin work within two weeks after the date they have been notified of the acceptance of their tender.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, for five per cent (5 p.c.) of the contract price, but no cheque to be for less than fifteen hundred dollars, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works, Ottawa,
Tuesday, April 22, 1916.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—1147.

Tenders for Diaphragm Pumps

Tenders will be received by registered post only, addressed to the Chairman Board of Control, City Hall, Toronto, up to noon on Tuesday, May 9th, 1916, for the supply of Two Gasoline-driven Diaphragm Pumps.

Envelopes containing tenders must be plainly marked on the outside as to contents. Specifications and forms of tender may be obtained at the Works Department, Room 6, City Hall. Tenderers must comply strictly with conditions of City By-law as to deposits and sureties, as set out in specifications and forms of tender. The lowest or any tender not necessarily accepted.

T. L. CHURCH (Mayor),
Chairman Board of Control.
17-17

CITY OF LONDON, ONTARIO

Storm Sewers and Sewage Disposal Works

Sealed tenders addressed to the "Chairman and Members Board of Control" will be received at the office of the City Clerk until 10 A. M., Friday, **May 12th, 1916**, for the following works:—

Contract 1—Wharncliffe, etc. .....2,300 Lin. ft.
Contract 2—Victoria, etc. ....6,000 " "
Contract 3—Waterloo, etc. ....4,400 " "
Contract 4—Elizabeth, etc. ....3,000 " "
Contract 5—Quebec, etc. ....2,400 " "
Contract 6—East End Sewage Disposal Works.

Specifications, forms of tender, plans, profiles, etc., may be seen at the City Hall, London, or at Room 204 Mail Bldg., Toronto, after May 1st, 1916.

Each tender is to be accompanied by a marked cheque as called for in the Instructions to Bidders.

The lowest or any tender not necessarily accepted.

H. A. STEVENSON, Esq., Mayor.
H. A. BRAZIER, Esq., City Engineer.
CHIPMAN & POWER, Consulting Engineers.
April 24th, 1916.

FOR SALE

Two low pressure 30 H.P. steel boilers complete with mountings, grates, etc. Have been in use less than two months. Good for steam or hot water heating purposes. Each will carry 3,000 square feet of steam radiation. Further particulars—MacM. R. & D., 4 Beaver Hall Sq., Montreal. 17-t.f.

FOR SALE—Asphalt Roller

One "Erie" 5-Ton Tandem Steam Roller, in perfect condition. Used about one week. Full specification and price upon request. P. O. Box 65, St. Catharines, Ont. 16-17

Construction Work

Superintendent or foreman on general construction work (Railway or Canal) on Concrete, Rock and Earth, wants position. Frank Brown, General Delivery, Sub-Station F, Toronto. 16-17

Reinforced Concrete Superintendent

Superintendent for past twelve years. Had full charge of some of the largest plants and buildings. Now open for engagement. A Martin, care of 51 Macpherson Ave., Toronto. 16-17

AGENTS WANTED

Canadian sales agents wanted for best line of excavating outfits made in the United States. Apply Box 393 "Contract Record & Engineering Review," Toronto, Ont. 17-19

Good Form Design Saves in Labor and Lumber on Building Work

Form designs should be arranged to reduce the number of special panels and pieces, should take into account the total quantity required, considering the movement of the forms throughout the job, and should furnish an accurate key to the quantity and size of stock required and to the order in which the component parts should be made, according to a paper presented at the twelfth annual convention of the American Concrete Institute at Chicago by R. A. Sherwin, of the engineering force of the Aberthaw Construction Company.

Such a design requires a careful study of the building plans, with a view to having modified such details as would make the form work unnecessarily expensive, and the immediate preparation of a progress chart. The latter is usually determined by the time allowed for completing the biulding. As soon as it has been prepared, the quantity of forms and the order in which they are to be erected and moved can be determined. This chart also shows when the form design must be ready to allow sufficient time for making up and erection.

A conference is then held between the man in charge of form design and the field men, at which the sizes and kind of lumber that will be cheapest and that can be delivered on time are determined. The point at which work must begin and the location, type and capacity of the concrete plant must also be settled. The general scheme of the form work should be outlined at this conference with field men to make sure that the design is understood and acceptable to them. If this is the case, they can carry it out much more readily. The first study and drawings are made from a general assembly, which is selected from different combinations as the most economical for the conditions. Joists and girts should be in as few lengths as possible. Stock sizes of lumber should be used.

Business Buildings and Industrial Plants

(Continued from page 45)

an ice plant fo rthe City Hospital Board has been awarded to the Canadian Ice Machine Company, 250 Wellington St. Approximate cost, $13,645.

The contract for masonry, carpentry, steel work and roofing required in an addition to the premises of the Zimmerman Manufacturing Company has been let to George Frid Company, 701 Bank of Hamilton Building. Approximate cost of building, $25,000.

The general, masonry and carpentry contracts for an addition to the premises of the Steel Company of Canada, Hess Street North, have been let to R. A. Campbell, 117 Duke Street, and the roofing to T. Irwin & Son, 22 McNab St. S.

London, Ont.
The general contract for remodelling a store for J. G. Steele, Dundas Street, has been let to S. Willis, 765 Talbot St. Estimated cost, $3,500.

Merritton, Ont.
The contract for the construction of an electro-chemical plant for the Riordan Pulp & Paper ompany has been awarded to the John V. Gray Construction Company, 59 Marmaduke Street, Toronto. Estimated cost, $30,000.

Montreal, Que.
The following contracts have been let in connection with the stores which are being built by William Boivin, 317 Fourth Avenue, Rosemount, for E. De Hivers:—mill work, H. Beaucage, Sorel; roofing, Samuel & Frere, 562 Panet Street; heating, plumbing and electrical work, G. Champagne, 78a Inspector Street.

The following contracts have been let in connection with the erection of an emergency hospital for the Montreal Locomotive Works, Limited, Longue Pointe, Montreal: — structural steel, Structural Steel Company, 10 Cathcart Street; roofing, Sibley & Huot, 34 Martin Street; plastering, Watson & Wilson, 1678 Hutchison Street; reinforcing steel, A. H. Cederberg, 10 Cathcart Street; plumbing, L. E. Moulton & Company, Limited, 142 Inspector Street.

Montrose, Ont.
The general contract for the construction of round house, coal dock and other buildings for the Michigan Central Railway Company has been let to Walbridge & Aldinger, Detroit, Mich. Estimated cost, $250,000. Brick and concrete construction.

Ottawa, Ont.
The general contract for constructing gymnasium rooms for the Y. W. C. A. Hintonburg Branch, has been awarded to J. H. White, Eastview, near Ottawa. Approximate cost, $7,000.

In connection with the erection of a power station on Slater Street for the Imperial Realty Company, the contract for construction of building has been let to John Sutherland, 216 Cooper Street, and for supply of steel, boilers, refrigeration plant, etc., to the Campbell Steel & Iron Works, 855 Carling Avenue. Brick and concrete construction. Approximate cost, $30,000.

Peterboro, Ont.
The contract for cement required in the erection of an addition to the premises of the Bonner-Worth Company has been let to H. Shurter, 599 King Street, and the carpentry to William Padgett, 576 Boliver Street.

Pointe aux Trembles, Que.
The general contract for the construction of an oil plant for the Imperial Oil Company, Limited, 918 St. Patrick St., Montreal, has been let to the James Shearer Company, Limited, 225 St. Patrick Street, Montreal. Work consists of an underground viaduct of reinforced concrete, mechanical and stores building, power house, boiler house and transfer pump house. Structural steel will be supplied by the Structural Steel Company, Limited, 10 Cathcart Street, Montreal.

Saskatoon, Sask.
The City Council have let the general, masonry, carpentry, steel, roofing, plastering and painting contracts for an addition to the power plant to James Priel. Estimated cost, $9,882.

St. Catharines, Ont.
The general, masonry, carpentry, steel, roofing and plastering contracts for the erection of an office building for the Waterloo Mutual Fire Insurance Company have been awarded to Casper Braun, 295 King Street W., Berlin. Approximate cost, $5,500.

In connection with the factory now in course of erection for the Dominion Food Company, the contract for steel work has been let to the Hamilton Bridge Company, Bay Street, Mamilton, and the painting to Begy & Son, Company, James Street.

Three Rivers, Que.
The contract for structural steel required in an addition to the plant of the Canada Iron Foundries Ltd., 7 St. Maurice Street, has been let to Canadian Bridge Company, Walkerville, Ont. Remainder of work by general contractor.

Truro, N.S.
R. O. McCurdy, Willow Street, has let the contract for heating and plumbing required in the erection of a store and office to F. Dexter, and the electrical work to W. Conn.

Vancouver, B.C.
In connection with the addition to the premises of the American Can Company, 535 Railway Street, the contract for installation of an elevator has been let to the Otis Fensom Company, New York, N. Y.

The general contract for the erection of an addition to the plant of the Begg Motor Company has been awarded to the Dominion Construction Company, 509 Richards Street. Approximate cost, $15,000.

Residences

Aylmer, Ont.
F. H. Kent and A. W. Pierce are each considering the erection of a residence on Talbot Street, to cost about $3,500.

C. M. Smith, Wellington Street, proposes to build five residences. Frame construction.

A. W. Pierce has had plans prepared for a residence to be built on Talbot Street, at an approximate cost of $7,000. Brick construction.

Bromptonville, Que.
Mrs. O. Lambert has decided to rebuild her residence, which was recently destroyed by fire. Approximate cost, $6,000.

Essex, Ont.
Work is about to start on the first of two frame residences to be built for John T. Rogers. Work will be supervised by owner.

Guelph, Ont.
W. H. Mahoney, Telephone Building, is receiving tenders on the erection of a residence for A. J. Frank, Oxford St. Stone and brick construction. Estimated cost, $3,500.

Hamilton, Ont.
W. Tomes, 22 High Park Avenue, is receiving tenders on the construction of twenty residences. Frame construction.

J. A. Armes, Federal Life Building, is preparing plans for a residence for T. S. Orr, Main Street, and will call for tenders shortly. Estimated cost, $12,000.

E. R. Bond, 652 Main Street E., has had plans prepared for two residences to be built on Cedar Avenue, at an approximate cost of $3,600. Brick and concrete construction.

Hullett Township, Ont.
Plans of a residence to cost about $3,200 are being prepared by John Brigham, Concession 12, Blyth. White brick construction.

Joseph Wheatley, Concession 13, Blyth, proposes to build a residence at an approximate cost of $3,000, and is preparing plans. White brick construction.

Kingston, Ont.
Isaac Allan, 98 Victoria Street, has commenced the erection of two residences, estimated to cost $5,000. Brick construction.

Listowel, Ont.
F. W. Hay, Main Street, has started work on a double residence, estimated to cost $4,000. Red pressed brick construction.

Work has been started by E. B. Smith on the erection of three brick residences on Main Street. Estimated cost, $7,500.

John Granger has commenced the erection of a residence on Inkerman Street, estimated to cost $3,000. Red pressed brick construction.

London, Ont.
H. C. McBridge, Edge Block, has plans in course of preparation for a double residence to cost about $6,000 and apartments estimated to cost $7,000.

Mitchell, Ont.
W. B. Barley intends to prepare plans for a residence to cost approximately $3,000.

F. C. Hord intends to prepare plans for a residence to cost about $3,000. Brick construction.

David Etty proposes to build a residence on Toronto Street, and will prepare plans. Approximate cost, $3,000.

Outremont, Que.
J. C. Perron, 722 Outremont Avenue,

intends to build residences on Querbes Avenue, at an approximate cost of $8,000. Brick and concrete construction.

Port Rowan, Ont.
Plans of a residence to cost about $3,000 will be prepared by W. P. Ferriss, Ellis Street.

Quebec, Que.
Plans of a residence are being prepared for E. Beaudoin, 256 Prince Edouard Street, and work will start early in May. Approximate cost, $6,000. Brick and concrete construction.

O. S. Laviolette has started work on a residence, estimated to cost $3,000. Brick and frame construction.

Leon Nadeau, 105 Franklin Street, has commenced the erection of a residence, estimated to cost $8,000. Brick and concrete construction.

D. Pare, 197 Third Avenue, propose to build a residence, at an approximate cost of $5,000, and will probably start work early next month. Brick and frame construction.

A. Faucher, 20 Joliette Street, has commenced the erection of a residence at St. Sauveur and Arage Streets. Brick and frame construction. Estimated cost, $3,000.

South Porcupine, Ont.
The Dome Mines, Limited, are preparing plans for about forty houses to accommodate their married workmen.

Toronto, Ont.
J. T. & H. Hutson, 43 Victoria Street, have commenced the erection of a residence at St. Andrews Gardens, and will let the smaller trades. Estimated cost, $6,000. Brick construction.

W. Moad, 46 Oakwood Avenue, has had plans prepared for duplex residences to be built on Oakwood Avenue, and will let smaller trades. Approximate cost, $5,000. Brick construction.

S. B. Green, 111 Evelyn Crescent, is building a residence on High Park Avenue, estimated to cost $3,500. Smaller trades will be let. Brick construction.

Work has been started by S. B. Green, 111 Evelyn Crescent, on the erection of a residence on High Park Avenue, estimated to cost $3,500. Brick construction. Smaller trades will be let.

P. L. Speirs, 95 Glenholme Avenue, is about to commence the erection of a duplex residence, estimated to cost $6,500. Smaller trades will be let. Brick construction.

Plans have been prepared for a residence to be built on Forest Hill Road by C. E. Tyler, 85 Cumberland Street. Contracts for smaller trades will be let about the end of next month. Approximate cost, $5,000.

Winterbourne, Ont.
Charles Goetz is about to start work on a residence, estimated to cost $3,000. White brick construction.

CONTRACTS AWARDED N N

Alderstot, Ont.
In connection with the erection of a residence on Ontario Street for F. W. Easterbrook, the contract for masonry has been let to T. Jones, 241 Prospect Street, Hamilton, and the carpentry to A. Coates & Son, Burlington.

Chatham, Ont.
The general contract for the erection of a residence for J. H. Burnie, 173 Adelaide Street S., has been awarded to Frank Sparks, Sandys Street, the painting to C. R. Guy, 8 Poplar Street, and the heating to the Watt Heating Company, King Street. Brick construction.

The general contract for the erection of a residence for Louis Palmer, Patteson Avenue, has been awarded to G. W. Rayment, 228 Thames Street, and the heating and plumbing to J. C. Wanless, King Street. Approximate cost, $4,500.

Grey Township, Ont.
The general contract for the erection of a residence for William Menary, Concession 9, has been let to Charles Seel, Cranbrook. White brick veneer construction. Approximate cost, $3,000.

Hamilton, Ont.
The general, carpentry and roofing contracts for the erection of two residences for Alexander Stewart, 615 Main Street E., have been awarded to E. H. Jones, 37 Senator Avenue. Estimated cost, $3,500.

Hebron, N.S.
Work is about to start on a residence for Knowles E. Crosby. General contractor, A. M. Knowlan, Hebron. Approximate cost, $4,000.

Hullett Township, Ont.
L. Hill, Blyth, has been awarded the contract for the erection of a residence for John Scott, Concession 10, Blyth. Frame and white brick construction. Estimated cost, $3,000.

Kinburn, Ont.
R. Groves has let the general contract for the erection of a residence to R. A. Kemp, 149 First Avenue, Ottawa. Frame and brick construction. Approximate cost, $11,000.

Listowel, Ont.
The general contract for the erection of a residence on Wallace Street for N. A. Gowdy has been awarded to N. Calder, and work will start shortly. Estimated cost, $3,000. Red brick construction.

Henry Karges has let the contract for the erection of two residences on Inkerman Street to W. H. McLachlan. Approximate cost, $4,000. Red pressed brick will be used.

The general contract for the erection of a residence for Ezra Reihm has been awarded to George Wahl. White brick construction. Approximate cost, $3,000.

Montreal, Que.
The general contract for alterations to a residence for the Ste. Elizabeth Society, 29 Seymour Avenue, has been let to R. Laberge, 141 onvent Street. Estimated cost, $5,000.

The general contract for the erection of a residence on Rosemount Street for the Trustees of St. Jean Berchmans has been awarded to T. Belanger, Valleyfield, Que., the heating, plumbing and roofing to T. Laturoelle & Son, Ltd., 6 Craig Street W., and the electrical work to J. A. St. Amour, 2171 St. Denis St. Estimated cost, $24,000.

Overbrook, Ont.
O. Jolcouer has commenced the erection of a residence at King and George Streets, and has let the electrical work to H. L. Allan, 373 Somerset Street. Approximate cost, $3,000.

Port Burwell, Ont.
The general contract for the erection of a residence for C. Sampson has been let to W. Morley, and work will start shortly. Frame and brick construction. Approximate cost, $3,000.

Quebec, Que.
P. N. Mathieu, Montmorency Village, has commenced the erection of a residence on First Avenue, Limoilou, for J. M. Dore, St. Gregoire De Montmorency. Brick and frame construction. Estimated cost, $3,000.

L. E. Labrecque, 128 Bridge Street, has let the general contract for the erection of a residence to G. Pare, 7 Laliberte Street. Brick and frame construction. Estimated cost, $5,000.

Sault Ste. Marie, Ont.
The contract for foundations and brick work required in the erection of a residence for R. T. Lane, 10 Queen Street, has been let to McLarty Brothers, and the carpentry to William Oben, Murray Street.

Toronto, Ont.
The following contracts have been let in connection with the residence being built for P. Morgan, 68 Bellefair Avenue:—masonry, H. A. Dancy & Son, Ltd., C. P. R. Building; carpentry, McMillan & Turner, 39 Huron Street; plumbing and heating, R. F. R. Maxwell & Company, 367 Queen Street W.; plastering, J. Robertson, 615 Lansdowne Avenue; painting, Taylor & Company, 9 Bloor Street E.; wiring, A. E. Paradine, 1987 Queen Street E.; roofing, W. E. Dillon Company, Limited, 183 George Street. Approximate cost, $9,000.

In connection with the erection of a residence for H. Fussell, 201 Howard Park Avenue, the contract for heating and plumbing has been awarded to Purdy, Mansell, Limited, 63 Albert Street, and sheet metal work to G. M. Bryan, 524 Yonge Street, and the wiring to R. A. L. Gray & Company, 85 York St.

Work has been started on the erection of a residence and garage for A. E. Whatmough, 491 Keele Street, and the contract for masonry let to Purton & Chennelle, 158 Ellsworth Avenue. Estimated cost, $3,500.

In connection with the residence being built on Jackman Avenue by J. T. Twigg, 28 First Avenue, the masonry has been awarded to William Bully, 119 Dinnick Crescent, and the carpentry to Kay Brothers. Approximate cost, $3,500.

Work has been started on the erection of a residence for J. H. Bone, 18 Toronto Street. General contractor, William Vokes, 228 Rusholme Road. Brick construction. Estimated cost $5,000.

Vancouver, B.C.
In connection with repairs to a store and apartments for Evans, Coleman & Evans, 407 Granville Street, the contract for roofing and sheet metal work has been let to Campbell & Grill, 331 Georgia Street E.; beams and tile work electrical work to the Jarvis Electric Company, 570 Richards Street, and the heating and plumbing to E. A. Bailey, 536 Helmcken Street.

Verdun, Que.
Anglins, Limited, 65 Victoria Street, Montreal, have commenced the erection

(Continued on page 50)

of a residence for J. Lyman, Willibrords Avenue. Estimated cost, $3,500. Brick construction.

Windsor, Ont.
The general contract for the erection of a residence for J. C. Pennington, La Belle Building, has been awarded to William Dupuis, 147 Dougal Avenue. Approximate cost, $5,000.

Power Plants, Electricity and Telephones

Goderich Township, Ont.
The Goderich Township Municipal Telephone Company propose to construct a line between Holmesville and Clinton, a distance of about four miles. Clerk, N. Trewartha, Holmesville.

Ottawa, Ont.
Tenders on the supply of ten knots of single conductor submarine cable will be received until 4 p.m., May 15th, by R. C. Desrochers, Department of Public Works, Ottawa. Specifications at office of the General Superintendent, Government Telegraph Service, Ottawa.

Regina, Sask.
D. C. McNab, Deputy Minister of Telephones, will receive tenders until noon, May 6th, on the supply of glass insulators, toppins, connecting sleeves, cross arms, galvanized iron and steel strand wire, pole line hardware and anchor rods. Specifications at the Department.

Truro, N.S.
The Town Council propose to purchase and remodel the Chalmers Electric Plant. Boilers, blowers, stacks, pumps, engines, generators and motors will be required.

Walkerton, Ont.
The Town Council intend to secure estimates on the installation of a power and lighting distribution system. Clerk, A. Collins.

Whitby, Ont.
Tenders on the installation of a fire alarm system will be received until May 1st, by Harry Watson, Chairman of Committee. Town Clerk, Joseph White.

CONTRACTS AWARDED

Kincora, Sask.
The contract for the construction of the Kincora Rural Telephone Company's system has been let to Brown & McKenzie, care of E. H. Joll, Kindersley, Sask. Cost, $12,040.

Fires

Brant Township, Ont.
Barns of Alexander McIntyre, Concession 9. Loss, $7,000. Will rebuild.

Broughdale, Ont.
Mill owned by Milton Sutherland. Loss, $6,000.

Charlesbourg, Que.
Stable and barn of C. T. Parent. Loss, $3,000. Will rebuild.

Fredericton, N.B.
Premises of Fredericton Steam Laundry and Smith Foundry Company. Loss, $5,000 each.

London, Ont.
Stables owned by F. Cline, 507 Queen's Avenue. Loss, $6,000. Will rebuild.

Mill Creek, B.C.
Chipping shed and drying kiln of the British Columbia Sulphite Fibre Company, Standard Bank Building, Vancouver. Loss, $40,000.

Port McNicoll, Ont.
Store of P. H. Beattie. Loss, $3,000.

St. Thomas, Ont.
Barns owned by J. B. Turner. Loss, $3,000.

Miscellaneous

Burlington, Ont.
The Town Council will receive tenders until May 13th on the supply of a combination chemical engine and hose truck. Clerk, J. S. Allen.

Hamilton, Ont.
The Board of Control will receive tenders until 5 p.m., May 8th, for the supply of mechanical rakes and appurtenances for the Gage Avenue pumping station. Engineer, A. F. Macallum.

Toronto, Ont.
The Board of Control will receive tenders until May 9th for the supply of two gasoline-driven diaphragm pumps. Specifications at Room 6, City Hall.

CONTRACTS AWARDED

Halifax, N.S.
The City Council have let the following contracts for supplies:—cast iron pipe, Drummond McCall & Company, 28 Victoria Square, Montreal; castings, Dartmouth Foundry Company, Maple Street, Dartmouth; lumber, Brookfield Brothers, Limited; cement, J. C. Calder, Central Whtrf; brick, Rhodes, Curry & Company, Windsor Street; drain pipe, E. F. Stevens, 16 Prince Street.

Kingston, Ont.
The City Council have awarded a contract for the supply of refined asphalt to the Aztec Oil & Asphalt Refining Company, 83 Craig Street, Montreal, at $26.31 per ton.

Montreal, Que.
The Harbor Commissioners have awarded the following contracts:—cement, Canada Cement Company, Ltd., Herald Building, Craig Street W., sand, Canada Sand & Gravel Company, Ltd., 486 William Street; broken stone, Rogers & Quirk, 1701 Iberville Avenue; rails and angle bars, Dominion Bridge Company, Ltd., Lachine.

Ottawa, Ont.
The Ontario Motor Car Company, 39 Queen Street, and the General Supply Company, Sparks Street, have each been awarded a contract for the supply of a flusher for the City Council. Prices, $7,150 and $7,800 respectively.

The Ottawa Improvement Commission have awarded the following contracts for supplies:—cement, Wright & Company, 25 Garneau Street, Hull; sand, Rideau Canal Supply Company, Canal Basin; lumber, McAuliffe Davis Lumber Company; hardware, McDougalls Ltd., Sussex Street.

Quebec, Que.
The City Council have let the following contracts for supplies:—stone, Quebec Brick Company, Quebec Railway Building; stone dust, J. J. Tierney, 204 Rorchester Street; lumber, J. H. Gignac & Son, 142 Church Street, N. Gignac, 68 La Lement Street, E. A. Hooks, 40 St. Francois Street, and O. S. Chalifour, Prince Edward Street.

Winnipeg, Man.
The City Council have awarded the contract for supply of the cast iron pipe to C. E. Chown, 147 Bannatyne Avenue.

Late News Items

Berlin, Ont.
Reitzel Brothers, Allan Street, have been awarded the contract for all work except heating, plumbing and electrical work required in the erection of a factory for the Onward Manufacturing Company, King Street W. Approximate cost, $10,000.

Hamilton, Ont.
The general, masonry and steel contracts for the erection of a block of stores and apartments for J. A. Morrow, 217 Caroline Street S., have been let to D. Tope, 191 Robinson Street. Approximate cost, $20,000.

Hull, Que.
The City Council will shortly call for tenders on the installation of a temporary plant for treating the water and will also have plans prepared for a permanent filtration plant, to cost approximately $200,000. Engineer, J. P. A. Laforest.

Kenogami, Que.
Price Brothers & Company, Limited, 56 St. Peter Street, Quebec, are considering extensions to their lumber mills, to cost about $200,000. Architect, A. Whipple. Concrete construction is probable.

The Town Council are having plans prepared for a Town Hall, estimated to cost $10,000. Architects, Syndicate des Engineers des Saguenay, Chicoutimi. Steel and brick construction.

Quebec, Que.
J. Lafrance, 21 Plessis Street, has commenced the erection of a residence, estimated to cost $8,000. Brick and concrete construction.

The Quebec Harbor Commissioners, Pointe-a-Carey Wharf, have let the general contract for the erection of a freight shed and grain galleries to J. Gosselin, 96 St. George Street, Levis.

The contract for the erection of a residence on Cartier Street for H. M. Cote, 631 St. John Street, to G. Cantin, 22 Lee Street. Approximate cost, $18,000. Brick construction.

The general, masonry and carpentry contracts for the erection of a factory on Ste. Helene Street for the Dominion Corset Manufacturing Company has been awarded to M. Cauchon, 307 Richardson Street. Brick and stone construction. Approximate cost, $50,000.

Radison, Sask.
R. M. Thompson, Masonic Temple, Saskatoon, is preparing plans of a school estimated to cost $14,000. Brick and concrete construction.

Sherbrooke, Que.
Ths Catholic Board of School Commissioners are having plans prepared for an addition to the school on First Avenue, to cost about $15,000. Brick and stone construction. Architect, J. W. Gregoire, 119a Wellington Street.

Toronto, Ont.
G. Ferrier, 302 Danforth Avenue, is receiving tenders on the erection of a garage, estimated to cost $6,500. Steel and brick construction.

Liability After Number of Years

An unusually interesting legal case is just now receiving prominence in Montreal, which concerns the liability of the contractor and architect for too rapid deterioration of materials used in the construction of a building. In this instance it is a case of dry-rot setting in in the timbers used in a spool thread factory and the owners have sued the contractors, Peter Lyall & Sons, and the architects, Brown & Vallance, for recovery of the cost of replacing the defective timbers with steel.

Brown and Vallance drew plans for this company in 1907 and they were submitted (by authority of the plaintiffs) to J. & P. Coates, an English firm, and received their approval. The work was begun in 1908 by the Lyall company. It appears that complaint of the construction work was made soon after the factory was occupied and the defendants in the case were asked to remedy the defects. Following their failure to do this the plaintiffs (The Canadian Spool Cotton Company) themselves ripped out the rotted wood and replaced it with steel at a cost of some $90,000. The Superior Court has already awarded $71,000 to the plaintiffs and it is against this judgment that the argument is now made before the Court of Review.

The contractors, as we read the evidence, argue that the timber used was according to specifications. For the architects it is maintained that the submission of the plans to the English firm removes responsibility from their shoulders, and that in any case neither they nor the contractors can be held liable for the cost of replacing the defective wood timbers with steel. It appears that the architects at one time offered $5,000 to settle the matter without litigation. This may be taken by the Court as evidence of their acknowledgement of liability. The judgment is awaited as we go to press, but whatever the immediate outcome, it looks like a question for the Privy Council.

In this same connection we ask the attention of our readers to a paper reproduced in this issue of the Contract Record read by Mr. Geo. H. Montgomery, K.C., of Montreal, before the Canadian Society of Civil Engineers. This paper is particularly interesting, especially at this time, to architects, engineers and contractors, in that one of the points discussed very fully is the liability to damage for a period of years after a building or engineering work has been completed.

The Load of Vehicles Act—Ontario

In 1915 Mr. Geo. S. Henry, M.L.A., for East York, introduced a bill in the Ontario Legislature which had for its purpose regulating and limiting the load vehicles might carry on highways. At that session of the Legislature the matter was discussed and allowed to stand over for one year. At the 1916 session of the Legislature Mr. Henry re-introduced the bill, and after it was referred to a sub-committee of the Municipal Committee, fully discussed and amended, it was given its third reading and is now law.

A number of the States of Union as well as certain European countries have adopted similar measures, but Ontario is the first of the Canadian Provinces to make it a Provincial measure.

In the early days of the Good Roads movement, an attempt was made to increase the width of tire and in this way limit the load per inch, but because of the large investment in narrow tired vehicles regulations of that character seemed impossible.

Then followed the motor truck with its four or five ton load, and the new conditions that were created each succeeding year as the weight and size of the trucks increased were leading to hopeless confusion had not Mr. Henry been successful in pressing this measure on the Statute books. In brief the terms of the bill are:

(1) No vehicle shall carry upon the highway a load, including the vehicle, greater than 12 tons or more than $4\frac{1}{2}$ tons on any one wheel.

(2) No vehicle shall carry a load, including the

vehicle, which will impose a greater weight than 650 lbs. per inch of tire on the highway.

(3) No vehicle shall have a greater width than 90 inches except traction engines, which are limited to 110 ins.

(4) The traction engine act is amended in so far as it conflicts with this act.

With this measure to act as a guide, Engineers will be in a better position than heretofore to work out economical designs for bridges, pavements and roadways.

A Few Plastering Hints

Builders often wonder why shrinkage checks and cracks appear in wall plaster. There are different reasons that might be given for this—plasterers are sometimes guilty of making their plastering mixtures too rich, the old guessed-at proportion of three of sand to one of lime or cement is quite unnecessary with the high grade mixtures that are in use today. Five or six or even seven to one gives a density which dries out more perfectly and causes no shrinkage after setting has taken place. The old proportion, being too rich, causes shrinkage cracks which admit moisture, which, on the action of frost, enlarges the checks and destroys the work. Even when there is no weather exposure, moisture and variation in temperature will soon enlarge small checks to unsightly proportions.

Another cause of checking or cracking is the lath, which may affect the plaster in several ways. If the lath is too dry when the plaster is applied, it absorbs water which, together with that which evaporates in dry weather, does not leave sufficient moisture for crystallization. This may be overcome by dampening the lath before commencing to plaster, enclosing the room to reduce the ventilation, so that evaporation will not take place so rapidly. A great deal of trouble in plastering is due to lath expending or buckling by the additional moisture from the plaster. This is overcome by proper nailing of the lath, leaving a space between the ends to allow for expansion and securely nailing to intermediate studding. Also the lath, for best results, should be uniformly spaced and of uniformly graded wood. Green lath, or lath with bark on, should never be used along side of lath properly seasoned.

Lathing and improper mixing are the causes of most difficulties seen in hard wall plaster. Use a little more care in the selection and nailing of the lath—a trade which too many men nowadays try to see how quickly can be done, rather than how well it can be done. Also use leaner mixtures and most of these difficulties can be done away with.

Revival in Brick

Florida these days is "eating brick." The building of brick roads has been given a strong impetus during the past year by the introduction of new constructional methods which make for durability. In Volusia county recently a contract was let to the Southern Clay Manufacturing Company of Chattanooga, Tennessee for 200,000 yards of 3½-inch wire-cut lug brick pavement, in the DelandLake Helen district, the brick to be laid on edge on a natural soil foundation and grouted. This road will be about 26 miles long, and nine feet wide except in Deland. In the latter place the roadway will be paved 50 feet wide. Many miles of this type of road were constructed in Orange county in 1915, and a large amount of yardage will be built in other sections during the current calendar year.

Canadian Research Bureau

The Canadian Research Bureau has been established, under a Dominion charter, to carry out research work in connection with the country's natural resources, including mineral, metal, hydro-electric and chemical branches. The Bureau has been established by the C. P. R. with the object of applying the results of the researches to Canadian industries; it is hoped to utilise many products now wasted, and to enable additional industries to be founded. The Canadian Pacific Railway aims to secure the mobilization of the ablest scientists and chemists of Canada, and to associate them with a central organization, to direct the activities of the scientists and experts engaged in research work in all parts of the Dominion. The discoveries and information gleaned by the central organization will be disseminated from time to time by bulletins. Mr. Arthur D. Little has been appointed to establish this central organization at Montreal. He is a past president of the American Chemical Society, a member of the Institute of Chemical Engineers, and a director of the Chemical and Engineer Department of the Institute of Technology. He is asking for the co-operation of scientists and chemists now engaged in research work.

Progress on Victoria Breakwater

The large work of constructing the reinforced concrete breakwater at Victoria is now well under way. Although no new records were established during last month, steady progress was maintained according to statistics compiled by the supervising engineers. Now, that the weather conditions are more settled, the contractors are satisfied that the work will proceed at a more rapid rate than has been the case during the winter months.

For the greater part of its entire length, the breakwater looms up well above the water-line, presenting a solid buttress of stone and concrete for over two-thirds of its length to seaward. The contractors are now concentrating operations at the extreme shoulder of the main arm, where divers are engaged in placing the huge granite blocks and levelling off the foundations at the commencement of the extreme arm of the seawall. As the work proceeds the operations are necessarily carried on at a lower level. Thousands of tons of coarse rubble continue to be deposited to form the foundations of the extreme arm, and as it reaches the desired level it is surfaced off for the reception of the granite.

It is interesting to note that since the contract was started no less than 1,082,800 tons of rubble has been dumped for the breakwater foundations. This tremendous amount of foundation includes 242,000 tons of what is technically known as "core."

There has also been placed to date a total of 108,900 tons of granite blocks, while 23,900 cubic yards of concrete, forming the superstructure, have been poured.

During last month, 22,300 tons of rubble were dumped; 7,700 tons of granite blocks were set in place and 1,700 cubic yards of concrete poured, making five blocks.—Rock Products.

The Might Directories, in their review of 1915, estimate the population of Toronto to be 544,456. The city contains 100,825 buildings of all varieties, situated on some 1,740 streets.

Shall I Build Now or Wait? Comparative Prices Today and at Outbreak of War

(Concluded)

Paints and Varnishes

CONSIDERABLE advance is noted in the price of most of the ingredients from which paints are made. Linseed oil today is selling at about $1.00 per gallon, as compared with 53c in the Fall of 1914; red lead has increased from 5c to 10c; zinc white, from 7c to 30c; lithophone, from 5c to 16c; pure white lead in oil, from $8.40 to $11.85. Red oxide of iron and graphite paint, frequently specified by engineers, has increased only about 40c per gallon, as the pigment is produced in this country. The advance on high grade liquid paint figures out at an increase of about 45c a gallon, while the advance on high grade white paint in liquid form, on account of high cost of metals, has been about 60c a gallon.

So far as varnishes are concerned, there has been comparatively little advance, but owing to the higher cost of the gums and linseed oil used in their manufacture, it is stated that an all-round advance is coming.

We are indebted for the above figures to the Canada Paint Co. The International Varnish Co. advise us that, excepting for limited lines into which various ingredients enter which have previously been secured from Germany, the varnish prices are the same as at the outbreak of war.

Fire-proofing Material

There does not appear to have been any appreciable increase in the cost of fire-proofing material. The National Fire-proofing Co. advise that prices are approximately the same as before the war broke out. Whether there will be an increase in the immediate future depends largely on the demand, the cost of fuel, and the difficulty of obtaining labor.

Glass

The following information, for which we are indebted to Mr. Edwin Hill of the Toronto Plate Glass Importing Co., sums up the glass situation.

The conditions in the glass market are abnormal, and may be said to be acute, from the jobbers point of view, as it is difficult to get supplies of glass at all. The immediate cause of the shortage is the great revival of building in the U. S. A. 1914 with the U. S. A., as with us, was a declining year, and when war was declared, the building trade simply died. This circumstance gave the Canadian glass importers some relief in getting supplies which were cut off from Europe. In the U. S. A. the domestic demand had fallen off so heavily that it scarcely absorbed 50 per cent. of their production. In plate glass, 1915 opened for U. S. A. manufacturers with scarcely an order in sight, and prices declined 25 per cent. or more. The larger works pressed hard to secure export business in Great Britain and her colonies, and towards the end of 1915 good orders were received, because Belgium, the great supplier of plate glass, is under control of the Germans.

The stagnant condition caused three large U. S. A. plate glass works to close indefinitely, due to ruinous price cutting. However, November 1915 saw a remarkable change, as, with the three works closed and the export business taking one-third of the production of the U. S. A. factories, the largest American jobbers began to lay in stocks for fear of being left without glass. The 1916 revival of United States building, however, has resulted in these jobbers being over-sold. It is thus evident why the Canadian jobber finds it difficult to get glass at all.

August 25, 1915, saw the lowest price plate glass was ever sold at in the United States. On November 1, 1915, prices advanced 10 per cent., on December 20, 1915, another 10 per cent., on February 1, 1916, another 35 per cent., and other advances are pending. As noted already, however, it is not the cost the Canadian jobber has to contend with so much as the shortage of supply.

The sheet glass (common window glass) situation is not quite so acute, but generally speaking, the same factors have entered into it, only in a more modified form. Glass is now coming into Canada bought at 85 per cent. increase on 1914 prices, and further advances are expected.

The Luxfer Prism Co. advise that they are getting a number of their own lines at the same prices as when war started. The demand has been small and they have been supplied through advance contracts. Regarding such lines of window glass as they use for leaded and steel windows, they figure the cost, including war tax, has advanced from 30 to 35 per cent. Manufacturers, however, generally have withdrawn their prices, as they are subject to continual advance.

Beaver-Board

As many houses and offices are now trimming in beaver board, this is becoming a more important factor in the total cost. There has apparently been no change in the price of this material; so the Beaver Board Companies advise us. They state that the price of raw material has gone up from 50c to $1.00 a thousand square feet, but that no increase in the finished product has been made, as they have felt it would be better to absorb the additional cost themselves, during the present period of stress, than to ask the consumer to carry it. The beaver board business in Canada is growing rapidly, and, so far, this year shows a big increase over 1915.

Steel

The price of steel today, as compared with a year ago, depends to a considerable extent on how soon the material is wanted and whether or not the fabricator is covered by a contract with the mills, made several months ago, covering present specifications. There is also a considerable variance in the price of steel, depending on the sections required, and we do not believe that an authoratative statement can be made as to the exact increase. On some items, wanted quickly, the plain material may run from 50 per cent. to 100 per cent. higher than a year ago, but as the fabricating shops are not busy, the actual cost, to the consumer, of delivered steel work would be increased only by the increased cost of the raw material, which might be anywhere from 15 per cent. to 30 per cent. The item of steel is, of course, a negligible one in residence construction.

Electric Wiring

The cost of electric wiring has been affected most by the increased cost in copper, but practically everything else that is used in the wiring of a building has been increased in price—switches, plates, screws, and so on. Copper wiring has increased, depending on the class of wire, anywhere from 60 per cent. to 100 per cent. At a rough estimate, the wiring of a building would cost from 30 per cent. to 35 per cent. more than at the outbreak of the war.

Summary

Summed up, therefore, the whole situation with regard to building appears to be about as follows:—

Stone and sand—price somewhat easier.

Brick—fully 25 per cent. drop.

Cement—reduction of 10c to 15c a barrel.

Lime—no change.

Lumber and mill work—no change or slight advance, still considerably lower than 1912 and 1913.

Hard wall plaster—no advance.

Plumbing and heating—a considerable advance on account of higher metal prices.

Fire-proof doors, windows, sash, etc.—a considerable advance.

Papers and felts—big advances in spots, especially dye materials.

Metallic roofing—increase of 10 per cent. to 25 per cent.

Paints—increase varies.

Fireproofing materials—no increase.

Glass—increase of 50 per cent. to 60 per cent. and hard to get.

Varnishes—about the same.

Beaver board—no advance.

Steel—15 per cent. to 30 per cent. increase.

Electric wiring—35 per cent. increase.

Some Figures on the First Year's Operation of the Ontario Workmen's Compensation Act

After a year's operation the Ontario Workmen's Compensation Act, according to the annual report just issued, has fully justified its existence. It is intimated that under the present Act the relations between employer and employee have become more amicable, and as a result great benefits have been derived from the new legislation. Under the old arrangement where a workman had to sue and prove negligence on the part of the employer, (which he was often not able to do immediately on account of his physical disability), only a small proportion of accidents were dealt with and many judgments that might reasonably have gone in favor of the workman were never made. Under the present system, however, where all accidents have to be reported to headquarters within three days, compensation is given in many cases without delay and even though the workman may be at the time so far disabled as to know nothing of it. This is as it should be, because if an injured workman is to get compensation at all, the first few days, or weeks, is just the time he usually will need aid most.

Accidents in 1915

The report shows that up to December 31, 17,033 notices of accidents had been received and only 1,117 remained unadjusted at the close of the year. The assessments collected during the year 1915 amounted to $1,539,492.40, of which $1,186,221.62 was distributed or set aside for accidents. A net balance or surplus of $395,026.40 was left part of which will be remitted to employers in the form of lowered rates for the coming year.

The total number of accidents for which compensation was made was 9,829. Of these there were 8,544 cases of temporary disability, 1,034 of permanent, and 251 deaths. The largest number of accidents occurred from falling, rolling, and flying objects, namely, 2,587; the next from machinery and parts, 2,098; third, from falls, 1,100; fourth, dangerous substances, such as electric currents, 623; moving vehicles, 270; hoisting apparatus, 208; runaways and animals, 78. Out of these 773 cases developed blood-poisoning, of which four caused death and 11 amputation. There were 170,711 days lost, equivalent to 569 men's labor for one year.

The amount paid by the board for injuries and disablements required on an average 150 cheques daily, amounting to $3,600.

Where Accidents Occurred

There were 14,750 employers in Schedule 1 contributing to the Accident Fund, but not individually liable. For Schedule 2 there were 1,252 employers liable for payment of compensation fixed by the board, but not contributing to the Accident Fund. These included such bodies as railways and municipalities. There were also Crown cases, including the Timiskaming and Northern Ontario Railway and the Hydro-Electric Power Commission, who voluntarily placed themselves under the operation of the board.

The figures show that the average wage of those injured was $13.27 a week, the average age being 33 years, running between 81 years, the oldest, and 11, the youngest.

The largest number of cases reported were from York County, 1,868; Wentworth County, in which Hamilton is located, was second, with 919; Algoma, in which the big salt works are located, was third, with 473; while Sudbury, with the copper mines, was fourth, with 468. No payments are made except where the injury disables a man for at least seven days.

New Act Satisfactory

The act in general seems to be very popular. The workmen's attitude towards it needs no mention. The general attitude of the employers is indicated by the request of a large number who are not liable under the present provision for assessment or payment of compensation, who have expressed the desire to come under the terms of the act. According to the report, the act has been working smoothly and satisfactorily, and the many benefits seem to be generally recognized and appreciated by the employers and the workmen.

Reports have been made promptly and claims, for the most part, disposed of expeditiously. The old annoyance of litigation between employee and employer in case of accident has been removed, and the intricacies and hardships upon the workmen and their families of the old system of negligence, common employment and assumed risk, have been eliminated. Legal fees of any sort have been done away with. The act has increased the percentage of cases where compensation has been granted for injuries, and the number of dependents benefited is one of the most gratifying features of the report.

New Administration Building of the Hydro-Electric Power Commission of Ontario

OWING to the rapid increase of the business, and therefore of the staff requirements of the Hydro-electric Power Commission of Ontario, it was found that the old quarters in the Continental Life Building were too congested, and the board of directors decided in 1914 to erect a new office building. After various sites had been examined and considered, it was finally decided to build on University Ave. on part of the old Caer Howell property. The building is situated just below College St., with the main facade facing on University Avenue directly opposite the General Hospital. The architecture is simple classic, Greek design; front elevation, cut stone, with side and rear walls, brown pressed faced brick, cut stone window caps and sills. The feature of the main facade in an artistic portico with an arched roof, with a cast stone plate bearing the commission's name. Surmounting the portico are four large Ionic columns flanked by end pavilions, supporting an extended stone coping, the whole supporting the top or sixth storey.

Immediately under the portico the main entrance is situated, with the main double doors of solid bronze. The main entrance hall has a floor of white Renfrew marble with a dado of Bancroft white marble. All doors off this main entrance are solid bronze. An enquiry desk is placed in the main hall, off which are located the stairways and elevators, situated in interior bays.

Basement

The heating is by the forced hot water system, two large Spencer heaters supplying hot water to a tank directly over the heaters, which are automatic feeders burning buckwheat coal. Hot water is forced up throughout the building by two centrifugal pumps, operating one at a time or both in parallel, driven by two 2 h.p., 220 volts, 3 phase, 25 cycle, motors. Fuel room for the heaters is underground outside the building, and has a capacity for one car load of coal. There is a steel stack on the west side of the building in connection with the heaters.

There is also in the basement a private and a main

Fig. 1.—New Administration Building of the Hydro Electric Power Commission, University Avenue, Toronto.

dining room where lunch will be served for the employees; these rooms are separated by three large sliding doors which may be opened out for banquet purposes. There is also a large sitting-room adjacent to the dining room, and the necessary kitchen, which will be electrically fitted and operated, besides the pantry and refrigerator. Filing and stationery storage rooms, and a large vault room, take up the remaining basement floor space.

First Floor

The first floor, with the exception of the toilet and the switch board booth, is used entirely by the Accounting and Filing departments. The accounting department occupy two large rooms to the right and left of the main entrance, and the filing department occupy the rooms in the rear of the building. The files are steel, five files high single, ten double, set in rows of eighty. Files may be despatched to any floor by means of an automatic dumb waiter.

Second Floor

The second or executive floor contains the Board Room on the north west corner with a private office connected for the use of the Commissioners, Chairman's office and committee room connected to the Board Room by a private passageway, Chief Engineer's and Secretary's offices, and also a library and conference room. This floor throughout is finished in mahogany-finish, hollow steel doors and trim, with court linoleum, cemented directly to the concrete, in the main corridors and hall-ways. The Board Room is finished with oak wall panelling, real mahogany dados, oak floors, and beamed ceiling. Chairman's and Commissioners' rooms are finished in real mahogany with oak floors.

Upper Floors

The upper floors, which are all very similar in floor plan, contain the Municipal, Purchasing, Operating, Railway, Hydraulic, Station Equipment and Building, Line Construction, other departmental offices and drafting rooms, all arranged for maximum efficiency. These floors are finished in Circassion walnut-finish, hollow steel doors and trim. All floors with the exception of the ground floor have a drinking fountain at the head of the stairs.

Foundations

A great deal of difficulty was encountered with the foundations, part of the site being on artificial fill over an old ravine which ran diagonally across the lot. Below this ravine quick sand was encountered, which made it essential to sink the foundations to bed rock some sixty feet below ground level. The building stands on twenty-eight re-inforced concrete cassions, fifty feet high, sunk to bed rock—twenty-four cassions being 3 ft. 6 in. in diameter, and four, 6 ft. in diameter. The space between the piers is filled in with a reinforced web or wall which acts as a beam to support the walls of the building. Building was delayed materially owing to the difficulty with the foundations.

Construction is fire-proof, steel and re-inforced con-

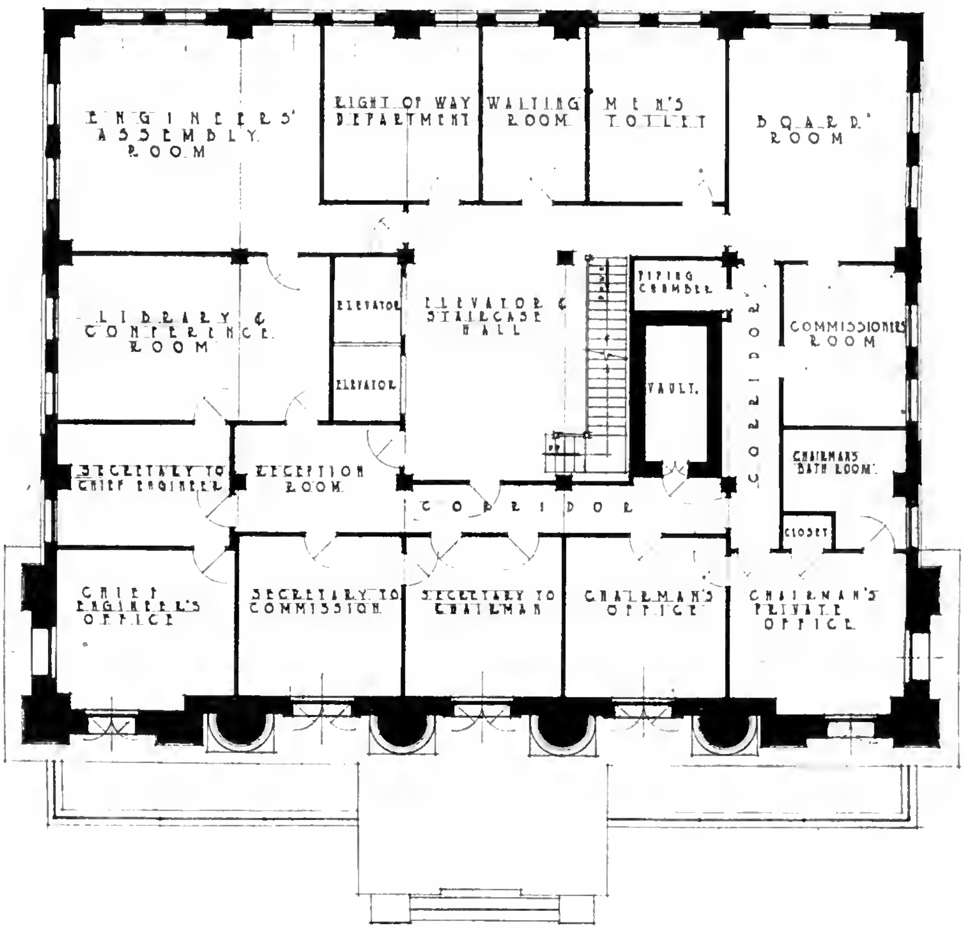

Fig. 2.—Plan of the second or executive floor—Administration Building.

crete, hollow tile floors and walls, steel stairs with mastic treads, court linoleum in corridors, oak floors in office rooms. All doors and trim are steel, in mahogany or walnut finish, windows are leaded glass with steel frames, walls are rough hard wall plaster, with picture moulding. A fire escape corridor from each central hall on each floor leads to steel fire escapes at the rear of the building.

Electrical Equipment

Electric power for lighting and power in the building is furnished by the Toronto Hydro-Electric System at 2,300 volts, which voltage is reduced to 230 and 115 by transformers in the transformer room. This room is a cement underground building on the north west corner of the larger building, and opens into the boiler and switch board room in the basement. There are three 30 kw. 2,200/230 v. Crocker Wheeler transformers for power, and two 20 kw. 2200/100 v. transformers for lighting, besides these are the storage batteries for the lighting and telephone systems.

From the transformer room cables are led underground through conduit to the switch board in the north end of the basement, which consists of two 18

Fig. 3.—Hollow tile floor and partition construction.

in. panels 8 ft. high, and 2 panels 24 in. wide, 8 ft. high, black slate. The board contains a high tension volt meter, 3,000 volts, a 400 kw. watt hour demand meter, two ampere meters, one for the total load and the other connected to measure the load on any circuit by simply plugging in the circuit to be read; two oil breakers and four, single phase, overload relays, complete the equipment on this half of the board. The other half contains the switches for the different circuits—elevators, vacuum, pumps, lights, dumb waiter, blueprint, etc. The switchboard equipment is Canadian Westinghouse.

A vacuum cleaning system, pump operated by 3 h.p. C.G.E. induction motor, has three outlets on each floor, the system is automatically controlled from all floors and may be started from any place in the building at the will of the operator, simply by pressing the button beside the outlet, which closes the switch on the switch board and starts the motor. There are two bronze elevators, electrically lighted, driven by two 25 cycle motors.

A novel system about the building is the automatic dumb waiter. This waiter runs in a flue, back and west of the main halls, which contains all cables, wires, pipes and plumbing outlets of the different floors. The waiter is automatically controlled from the ground floor by push buttons. On the request for files from any floor, they are put on the elevator and despatched simply by pushing the button corresponding to the floor. The elevator goes up to the desired floor, stops and turns on a bulls-eye light in the door. Opening any door on intervening floors automatically stops the elevator at that floor and thus prevents accidents.

Lighting Fixtures

Lighting outlets are lavishly installed through the whole building. Halls and corridors have semi-translucent, completely closed in, shades, while offices have semi-indirect lighting. The Board Room has an elaborate, bronze, candlestick chandelier. Every office is equipped with four base board receptacles for electrical appliances. All dark rooms are automatically lighted on opening the doors.

Telephone and Signal System

There is an automatic telephone system with a switch board in the boiler and switch board room in the basement. This system operates in connection with the company's private lines over the distributing system and the private lines to the store house and stock room, and also with the Bell system. The connection between the different lines is made in the telephone booth on the main floor. Telephones and signal systems are wired in all offices. Beside the dumb waiter is a telephone box on each floor from which cables lead to every room, so that at the least notice a telephone or a signal system between any two rooms may be connected without any interference to the office fittings.

Contractors

In placing contracts the Commission endeavored to use, where suitable, material manufactured in Canada, and, where possible, by Hydro power. The General Contractors were Witchall & Son, who covered excavation, concrete, brick and stone masonry, structural steel work, floors, interior partitions, in short, the structural portions of the building. The following are some of the sub-contractors of G. C. Witchall & Son, who use Hydro power in the production of material supplied by them:—pressed brick, Inter-Provincial Brick Co., Cheltenham; cement, St. Marys Portland Cement Co., St. Marys; cut stone work, Witchall & Son, Toronto; gypsum partition blocks, Ebsary Co., Caledonia; paint, Dominion Paint Works, Walkerville.

Other contracts which were placed direct by the Commission with contractors using Hydro power are as follows:—sash and casement, Trussed Concrete Steel Co., Walkerville; plastering, R. C. Dancy, Toronto; marble work, Canada Glass, Mantels & Tile Co., Toronto; hollow steel doors and trim, A. B. Ormsby Co., Toronto; elevators and dumb waiter, Otis-Fensom Elevator Co., Toronto; radiators, Steel & Radiation, Ltd., Toronto; iron valves, Canadian Fairbanks-Morse, Toronto; pumps, Canadian Buffalo Forge, Berlin; door hardware, Aikenhead Hardware Co. (Canadian Yale and Towne).

Some of the other contracts placed by the Commission were:—fire escapes, Dominion Ornamental Iron Co.; bronze work, Architectural Bronze & Iron Works; boilers, Waldon Heating Co.; switchboard, Canadian Westinghouse Co.; automatic Presto telephone switch board, Canadian Independent Telephone Co., Toronto; piping G. E. B. Grinyer; plumbing system, Keiths, Ltd.; plumbing fixtures, Imperial Products; smokestack, Toronto Iron Works; glazing, Toronto Plate Glass Co.

The Law and the Engineer and Architect

The Interpretation of Modern Specifications with Respect to the Relations Between Proprietor, Engineer and Architect

By Geo. H. Montgomery, K. C.*

To anyone familiar with the wording of the modern specification as drawn by the modern engineer, a paper upon the law and the engineer would seem superfluous, since the engineer would seem to be made a law unto himself, the decision of the engineer or the architect, as the case may be, being declared to be final in every second paragraph of the specification. However, the law has jealously guarded its prerogatives, and there is possibly no branch of our jurisprudence more complex than that surrounding the functions of the architect and engineer. In the province of Quebec this is particularly the case, since we are operating under a mixed system of law, French and English being cited and applied almost indiscriminately, with the result that varying as they do in their basic principles we are faced with a mass of conflicting jurisprudence, making the task of counsel who are called upon to advise, rather a difficult one. This is especially so in the branch relating to the responsibility of the architect or engineer for the stability of the work entrusted to him, as well as in that relating to the necessity, effect and finality of his certificate. In grouping the architect and engineer together I do so advisedly, as their duties and responsibilities are so analogous that the jurisprudence that has grown up can be applied to one or the other indiscriminately. So much so is this the case that it has been expressly held that the somewhat stringent and exceptional provisions which exist both in our own Code and in the Code Napoleon regarding the responsibility of architects, apply equally to engineers, notwithstanding the fact that in the application of these articles in every other respect they have been treated as exceptional provisions not to be extended beyond their literal terms.

Engineer's Ambiguous Position

Occupying as the engineer does a somewhat ambiguous position, in that he is called upon in practically every contract to act as agent and representative of the proprietor as against the contractor, and at the same time to act in a quasi-judicial position between the contractor and the proprietor, he must find his position an embarrassing one, and it is to the credit of the engineering profession that the resultant litigation of disputes is not even more frequent than it is found to be in practice. It must be admitted that the law has not done much to relieve him of his embarrassment, since as towards the proprietor, the party by whom he is employed, it calls upon him to exercise all the care and zeal which can be expected from one who is employed only in the interests of the proprietor, and at the same time severely criticizes him if he acts in other than an impartial manner as between the proprietor and the contractor whenever by the terms of the contract matters are referred to him for decision. Mr. Gregory, who was both a lawyer and an engineer, has attempted to reconcile his position in the following terms:—

"In accepting an appointment from the employer, the engineer or architect undertakes responsibilities to the employer under the contract, but to the contractor only under the law. To the employer he may be liable for an error in the performance of his duties; but to the contractor only for a fraud committed or aided by him, in the performance of his functions under the contract, or otherwise."

"As fraud and deceit are mala in se, and in the performance of functions under the provisions of a contract, as in every other transaction, a person is under the legal obligation to be a party to no fraud, and to make no false statement for the purpose of it being used to another's injury, the employer's direction or request to the engineer or architect as to the performance of his duties under a contract is no justification for a fraudulent performance of them."

"That his functions shall not be exercised in bad faith, is the extent of the engineer or architect's obligation to the contractor with whom he has no privity of contract; while to the employer, he may be under the obligation to duly perform all the duties which, by his acceptance of the appointment, he undertook to perform."

"Such disparity between the responsibility which the engineer or architect has to the contractor and that which he has to the employer, must necessarily exist where he is the agent, appointed solely by the employer, to exercise a control over a contractor who has no part in his appointment."

As a corollary to the proposition that no contractual relation exists or can exist except with the proprietor, and not with the contractor, it follows that the architect or engineer cannot be employed in the interests of both, or receive fees from both.

Quoad the Proprietor

In his relations with the proprietor we have to consider, first, the extent of his mandate and how far he can bind the proprietor. In this respect reference, of course, must first be made to the terms of the particular contract, but as a general proposition it can be laid down that while he is the agent of the proprietor he has only the power to bind him within the strict limits of his mandate, as it has been held that with regard to drawings and plans he has no implied authority to warrant they are correct, or that the work can be carried out in accordance with them, or that temporary constructional works, in the case of engineering contracts, are practicable. Again, the authority of the architect or engineer as agent does not empower him, without the knowledge or consent of his employer, to make promises that the conditions contained in it will be followed or waived, or, if there are omissions in the drawings, plans or specifications, to order as extras such things omitted as are necessary to complete the contract, or where the scheme is impracticable, to order as an extra work which is necessary to enable the works to be constructed. It is laid down as a principle that the architect or engineer has no general authority to vary, waive or dispense with any of the conditions contained in the contract without being specially authorized to do so, and even where he is authorized by the contract to give directions as

* Before C. S. C. E., Montreal.

to the manner in which the contract is to be carried out, he can only give such directions as fall within the contract, and may not vary the whole scheme of the proposed works, or allow the substitution of entirely different materials for those specified in the contract. Again, an architect or engineer has authority to order extras only when the contract so provides, and then only to the extent provided therein. He cannot waive or dispense with a condition that extras shall be ordered in writing, or any similar condition. It is to be noted, however, that if he has power by a final and conclusive certificate to adjust the amount payable by the employer to the contractor, the employer must pay the amount certified for if the certificate is honestly given, although it may include extras not ordered in the manner prescribed in the contract.

Engineer's Relation to the Proprietor

As regards his duties and responsibilities towards the proprietor, they differ somewhat, as far as responsibilities are concerned, in this province, from the law which obtains in the provinces which are under the common law. Under the common law system architects and engineers are only required to exercise reasonable skill and diligence. As to the amount of skill required, the architect or engineer need not exercise an extraordinary degree of skill. It is not enough to make him responsible, that others of far greater experience or ability might have used a greater degree of skill, or even that he might have used some greater degree; the questions is whether there has been such a want of competent care and skill leading to the bad result as to amount to negligence. He is bound, however, to acquaint himself with the requirements of all public and local statutes, as well as to exercise reasonable precaution in the examination of the site on which the works are to be constructed. The mere approval of the plans and specifications by the employer will not exonerate the architect or engineer from liability when the design of the works is structurally defective, or does not carry out the instructions of the employer, although the employer has been told by the architect or engineer to examine them.

Responsibility of the Engineer

Under the civil law system in force in this province, the responsibility of the architect or engineer is more extensive. A presumption of fault is cast upon him and he is responsible jointly and severally with the contractor for the failure of the structure without evidence of special negligence.

(Articles 1688 and 1689, Civil Code)

"1688. If a building perish in whole or in part within ten years, from defect in construction, or even from the unfavorable nature of the ground, the architect superintending the work, and the builder are jointly and severally liable for the loss."

"1689. If, in the case stated in the last preceding article, the architect does not superintend the work, he is liable for the loss only which is occasioned by defect or error in the plan furnished by him."

These articles are in substance a reproduction of corresponding articles in the Code Napoleon. The origin of the principles thus laid down no doubt is to be found in the fact that in earlier days the architect was commonly the principal contractor for the building. At that time the trade guilds still flourished and one of the rules of the guilds was that no member of any guild should contract for or do work belonging to any other guild, so that the only way to include the whole building in one contract was to make an agreement with someone outside the trades and let him make the sub-contracts for the different portions of the work. The person with whom the principal contract was usually made would naturally be the architect, and as, like any other contractor, he would be tempted to save money for himself by surreptitious means to the detriment of the strength of the building, the law made him and his sub-contractors responsible for a fixed term for the solidity of the structure. It has been held that these articles fall within the category of matters of public order, and in consequence cannot be derogated from so as to relieve the architect or engineer from responsibility, even when so expressly stipulated.

With the idea of avoiding the rigorous responsibility thus imposed upon the engineer under the Quebec system, certain engineers have been stipulating that in the execution of the works they shall act merely as the servants, agents and employees of the proprietors, and perform the work under the proprietors' direction. Although the Code only makes use of the word "building," the jurisprudence is that the word will include any large undertaking such as a dam, or other analogous work. This liability has been imposed even in a case in which the plans were made by another architect before the persons sued assumed charge of the works to be erected.

The responsibility of the architect or engineer who not only prepares the plans but supervises the work, extends not merely to the sufficiency of the plans, but also to the materials employed. Thus in a case cited in this province where the floors of a building sank in consequence of the insufficiency of the timber specified, it was held that the architect and contractor were jointly and severally liable, and in a more recent case now pending in the Appeal Courts, the architects and contractor were held jointly and severally responsible for the failure of timber which perished through dry rot. [Mr. Montgomery cited as examples of this, the case of the Royal Electric Company vs. Wand, and Wand vs. Walbank].

Engineer's Certificates

In most building contracts it is customary to provide that payment shall only be made upon the certificate of the engineer, and that the latter shall be final and conclusive as between the parties. Here again we find a certain degree of conflict between the English jurisprudence and that of our own province. Under the English jurisprudence it is held that if the certificate of the engineer is made a condition precedent to any right of payment, effect will be given to the clause, and no action can be maintained against the proprietor until a certificate has first been procured.

As to the finality of the certificate, the English jurisprudence varies according to the wording of the particular contract. If a contract contains a provision that disputes shall be referred to arbitration, the certificate of the architect or engineer will not be treated as final, even though the same architect or engineer is by the contract named as arbitrator, and in order that his certificate should be treated as final, it must have been given before any dispute has arisen. Under our own jurisprudence there is some question as to the binding force and legal effect of such a clause, and we are face to face with a flat conflict of opinion upon the point. Thus, in a case of Mireau vs. Gauthier, it is held by one of the judges of the Superior Court, that the obtaining of an architect's approval and certificates, and an order for payment on the proprietor, when such is the agreement between the parties, was a necessary condition to any demand upon the proprietor and a condition precedent to any action for the recovery of the contract price. If the architect arbitrarily refuses to comply with the just demands of the contractor, the latter can take proceedings against him to compel him to perform his functions, but he could not proceed against the proprietor. On the other hand, another of the learned judges of the Superior Court, in the case of Quinlan vs. Redmond, came to an exactly opposite conclusion, supported by weighty argument and authority, to the effect that clauses of this nature in a contract were of no legal effect in this province, and that they were to be treated as general arbitration clauses, or clauses compromisoires, which could have no effect unless they comply with the rules of the Code of Civil Procedure, that is to say, unless they specified the particular subject of the dispute, named the delay within which the award shall be rendered, and complied with the other requirements of the Code.

Must be Impartial

In one respect the jurisprudence under both the common law system and the system in being in our province is in accord, and that is, that the engineer or architect called upon to exercise the quasi-judicial function must not be placed in the position where his opinion is likely to be influenced, at least to a greater extent than is known to both parties at the time the contract is entered into. In the latter connection it is no bar to the exercise of his functions that he is employed by the proprietor and is paid by him, and is, in a sense, the representative of the proprietor, since this is a fact which would have been well known to both parties at the time the contract was entered into. The mere fact that the engineer was in the permanent employ of the contractor would not affect the finality of his certificate, or the finality of his award in the adjustment of a dispute. If, however, a secret agreement existed between the proprietor and the engineer, such as an agreement that the engineer would only act as the servant, agent and employee of the proprietor, and in all things obey the latter's directions, this would absolutely disqualify the engineer from performing any judicial function as between the proprietor and the contractor. Again, it has been held, both here and in England, that if the architect or engineer has given the proprietor a guarantee that the works would not cost more than a certain amount, this would be a fact to so influence his judgment as to disqualify him from acting as an arbitrator, or granting any certificate binding against the contractor.

Remuneration

As to the right of the architect or engineer to remuneration, this will ordinarily be governed by arrangement. In the absence of an arrangement there will be an implied contract to pay what is reasonable, usually based upon the customary charges or commissions for similar work. Where drawings are merely submitted for approval, it has been held in England that no claim for remuneration arises unless the work is approved or used, and, similarly, in the case plans or drawings submitted in competition, subject, of course, to the public terms of the competition; such probationery drawings are in the nature of a tender, that is, a mere proposal or offer to do the work, and without acceptance there is no mutuality on which an implied contract to be paid for can be placed. [Here the writer discussed a case where the court decided that plans or drawings submitted for approval and used for any purpose, should be paid for].

Where an engineer is engaged at a yearly salary, payable monthly, it has been held in this province that the contract must be construed as being by the year, and that the words "payable monthly" are a mere indication of the manner in which such remuneration is to be paid. Silver vs. Standard Gold Mines Limited. In the same case it is held that a professional, e.g., an engineer with managerial functions is not obliged to seek for menial work if he cannot find a position equal in importance to that from which he has been dismissed unjustly, and the employer, in that event, is responsible for the payment of the salary for the entire period of the contract up to the date of its expiry.

Disposing of Plans

Ordinarily, unless some particular statute provides that the originals of all plans shall remain of record with the engineer or architect, the plans and specifications that have been prepared can be claimed by the owner. Thus:—

"An architect was employed by the owner of certain houses to design and carry out the conversion of the houses into flats, and he was to receive five per cent. on the contract price for his services. The architect accordingly prepared plans and specifications, and superintended the work of conversion. At the conclusion of the work the owner paid the architect his fees, and claimed to be entitled to the plans and specifications. At the trial the architect tendered evidence of a custom in the profession by which, in the circumstances of the case, the plans and specifications were the property of the architect:—Held, that the custom was unreasonable, and that the evidence was not admissible, and that the plans and specifications belonged to the building owner: Ebdy vs. McGowan (1870), 2 Hudson on Building Contracts 7; Gibbon vs. Pease, (1905) 1 K.B. 810, 74 L.J.K.B. 502, 69 J.P. 209, 53 W.R. 417, 92 L.T. 433, 21 Times L.R. 365. 3 L.G.R. 461."

Discussion

Mr. Montgomery then discussed the ordering of extras, stating that neither an architect nor an engineer could claim remuneration unless these were ordered in writing and unless the price was fixed in writing and agreed to by the proprietor. In dealing with the clauses providing for a time limit for the completion of contracts, where there was no penalty, damage was not payable unless it could be shown that time was the essence of the contract. Mr. Montgomery also took up the question of stipulated damages and penalties, and said that the courts were disposed to alleviate what might be regarded as an extreme application of the clauses. It had been held that in the case of a delay, say in the delivery of a site, the contractor was absolved from paying stipulated damages; in fact the courts generally sought a solution which tended to reduce damages payable by a contractor.

Several questions were asked, and Mr. Montgomery elaborated many of the points of his paper. A discussion which followed was taken part in by Sir John Kennedy, and Messrs. Francis, Surveyer, Ross, Duchastel and Swan.

Walter J. Francis & Company, consulting engineers, have removed from the Commercial Union Building, 232 St. James Street, to the new Bank of Toronto Building, 260 St. James Street, Montreal.

Canadian Imports and Exports for the Year Ending February 29, 1916

THE tables reproduced herewith summarize the export and import trade of the Dominion of Canada with the rest of the world for the 12 months ending Feb. 29, 1916. Comparative figures, showing the increase or decrease over the previous year, are also included. Total imports for the year amounted to $520,335,754.00, a decrease of about eighty millions from the figures of the previous year. The total exports were $862,782,899.00, practically double of the figures for the previous year, which leaves a balance in our favor of some $340,000,000.00. Most of our imports are from the United States, the total amounting to approximately $380,000,000.00. This is a decrease from previous years of about 10 per cent. The United Kingdom has given us imports to the value of $77,582,813.00, a drop of about 45 per cent.

34½ millions, as compared with less than 4 millions in 1914.

A moving picture machine is being used in connection with the clean-up campaign to be conducted in Montreal by the City Improvement Association. Contracts have been let for the printing of 75,000 booklets which will be distributed through the medium of the schools, by the members of the fire department and by an arrangement whereby they will be sent out with parcels from the large stores. For backyard gardens there will be a distribution of $1,250 in prizes. There will also be special contests for school children and arrangements are being made so that seeds can be sold for 1 cent per package. The campaign is being well organized and promises to be the most successful yet conducted.

An act to provide for compensation to workmen for injuries sustained and industrial diseases contracted in the course of their employment has been introduced in the Legislative Assembly of the Province of British Columbia.

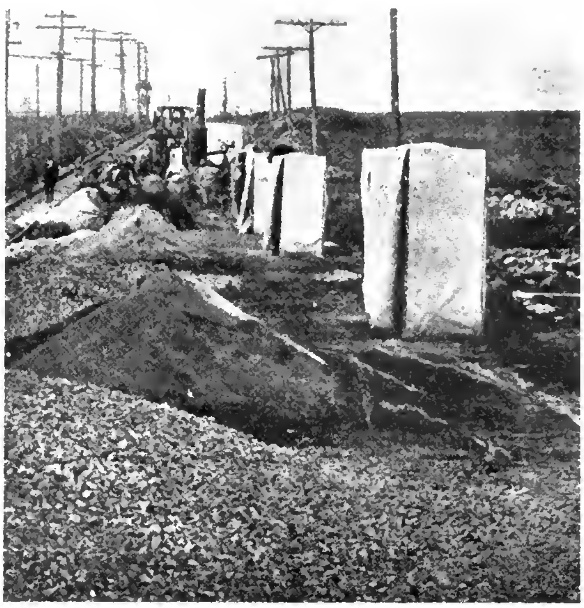
Bridge Building in Ontario

Forty-six new bridges were constructed throughout the Province of Ontario, under special appropriation, by the Department of Public Works, Mr. A. B. Halford, Provincial Engineer, during the season 1914, 1915. Of these, twenty-seven were timber bridges, pile and crib abutments, fourteen steel bridges on concrete structure, 4 steel bridges on timber abutments, and one large reinforced concrete culvert. Besides these, work was completed on several bridges under construction at the close of the fiscal year, 1914. All bridges were constructed by day labor under a regular staff of foremen, under the direct supervision of the Engineering Department. The cuts herewith illustrate a number of the bridges.

Some Novel Methods Used in the Construction of a Model Highway

HIGHWAY engineers will note with interest some of the features and unusual methods adopted by the Philadelphia State Highway Department in the model concrete road building between Easton and Allentown, a distance of approximately ten miles. Road engineers are paying more attention than ever in their endeavor to find a type of construction that will not only present a surface permanent enough to withstand present day traffic but will also be economical in the first cost and in maintenance charges. To determine the practicability of such a road, the Pennsylvania State Highway Department have, with the co-operation of the cement interests, undertaken to build this model road. The description of the work on the road was given by Mr. William D. Uhler, chief engineer of the department, before the recent American Roadbuilders' Conference, Pittsburg, in part as follows:—

In the construction of this highway, which is not yet completed, especial attention is and has been paid to every engineering detail, starting with the subgrading and drainage, thorough rolling of subgrade before placing materials, proper grading of aggregates, the exact proportioning of materials and the amount of water used. Other details closely watched are the timing of the mix, laying of the concrete, striking off and curing of the pavement.



Philadelphia Model Highway Construction—Canvas Huts for Sheltering Cement.

After the subgrade is finished accurately, drained and rolled, the forms are placed, which consist of 6-in. channels in 12-ft. lengths, held in place by steel pins; particular care being taken to have the alignment and grade of these forms accurate. The steel forms are being used both for economy and on account of the ease with which they can be handled.

Placing Materials

To eliminate the re-handling of materials, a system was devised for the proper distribution of the aggregate and cement. On this work all materials have been brought to the point of use on trolley cars, advantage being taken of the fact that the car tracks paralleled the full length of the road, making it by far the most economical way of handling the materials. This method of delivery proved advantageous for unloading sand and stone at measured intervals. Portable canvas sheds, holding 90 sacks each, used for the storage of the cement, were placed at measured distances along the route, and as emptied were moved ahead.

In proportioning the batches, the sand and stone were handled in specially devised wheelbarrows, of 3 cubic feet capacity, to insure accurate measuring, and when loaded these barrows were struck off with a shovel. The same care has been given with reference to the amount of water used in each batch, just enough being put in to secure a plastic mixture, which would not quite level down in the bucket when dumped.

Duration of Mix

Every batch of concrete is mixed for one and one-half minutes; the reason for this being that a number of experiments, made during the progress of the work, indicated that the greatest strength, commensurate with economy in cost of mixing, was obtained from a mix of this timing.

Before placing the concrete the subgrade is thoroughly wet and the concrete, which is mixed in proportions of 1:2:3, is placed to a depth of 6 in. at the side and 8 in. at the center. A heavy strike-board is then used to compact the concrete and give the road its proper form, and this board is followed by a lighter one. When the strike board comes within 3 ft. of a joint, it is lifted and placed alongside the joint. Work then proceeds away from the strike-board. After water disappears from the surface of the concrete, it is floated smooth with a wooden float. Transverse joints are placed 36 to 40 ft. apart and consist of a ¼-in. thick prepared bituminous material 9 in. wide. Part of the bituminous strip above the surface is sheared off after the concrete is placed, leaving it projecting about 1 in. above the finished surface. This part is flattened down by traffic and protects the joint. A split float is used to finish the concrete on each side of the joint, so that both sides will be at the same elevation. The edges of the joint are rounded with a 3/16-in. edger. The sides of the roadway slab are rounded with a ¾-in. edging tool.

Metal Protection Plates

Concerning the use of metal protection plates and of reinforcement in the road, Mr. Uhler says:

There is a vast difference of opinion as to the advisability of using steel protection plates at the joints. Experience leads me to believe that, if proper care is taken in the maintenance of the unprotected joints, built as outlined herewith, far more satisfactory and economical results will be attained than by the use of steel joints, especially if there is any difference in the rate of wear of the concrete and the steel in the joints. Only a thousand feet of this road has been constructed with steel protection joints, and up to the present time no advantage in this method of protection is noticeable.

The road in question is reinforced also with a light metal fabric, which is shipped to the job in sheets 5 ft. in width and 6 ft. and 10 ft. in length. This fabric is placed with longitudinal joints staggered and with a lap of 4 in. crosswise and 12 in. longitudinally. Of course, it would be preferable if sheets could be obtained the full width of the roadway. Reinforcing shipped in sheets, in my opinion, is more satisfactory because it is easier to handle and can be installed with less trouble, while with rolled reinforcement there is bound to be more displacement of the concrete when the workmen endeavor to force it into place.

This metal reinforcement is placed 2 in. below the top of the slab. It reduces the number and size of the cracks and is designed also to overcome longitudinal cracks that may occur because of the settlement of the shoulders.

Throughout the West the general practice is to build concrete roads, without reinforcement, 6 in. at the side and 8 in. in the center. Personally, I believe that far better results can be obtained at the same cost, and under some conditions at less cost, by the construction of 5-in. and 7-in. concrete roads with light metal-fabric reinforcement.

Protection While Setting

To protect it from the sun and air while it is setting, the concrete is shaded with canvas. Portable forms are used, which are set along the edges of the pavement and project about 12 in. above it. The canvas sheets are mounted on rollers laid on these forms and unrolled. After the concrete has hardened, the canvas is removed and the pavement is covered with two or three inches of earth and kept wet 10 to 14 days, when the road is opened to traffic. About 3¼ mi. of this road was completed last season, and thus far only two slight cracks have appeared.

Comparative Costs of Handling Gravel by Team and by Tractor for Roadwork

By O. L. Kipp*

THE data presented and the conclusions suggested are derived from the Gravel Checkers' records on five team hauling jobs totalling 22 miles of road gravelled and one tractor hauling job covering 3.6 miles of road gravelled; the gravel being placed at the rate of 15 cu. yd. per 100 ft. station on each job.

Team Hauling

Gravel hauling by team is familiar to all and no description of outfit or method is necessary, other than the statement that ordinary dump planks were used and 1½ cu. yd. per load were hauled uniformly. The team wagons were loaded by hand shoveling. The number of shovelers in addition to the teamsters shoveling varied from none for a portion of the time on Job No. 1 to a maximum of two on all the jobs.

The data obtained from the checkers together with percentages and averages derived therefrom have been compiled in the attached Table 1, in which is shown for each job and each haul length on each job, the following data: Total loads hauled, average number of teams hauling, average number of loads per team day, load miles per team day, per cent. of time dumping, per cent. of time in pit, per cent. of time required for loading at 12 minutes per load, minutes actually used in loading each load, per cent. of time lost in loading, average number of teams at the pit, hauling cost per cubic yard, total loading and hauling cost, contract price, and the hauling cost per cubic yard mile for each length of haul.

From the same table we also find that providing the time of loading were reduced to 12 minutes per load the hauling cost per cubic yard mile would be as follows: 0 to ½-mile haul, 43 ct.; ½ to 1-mile haul, 27.8 ct.; 1 to 1½-mile, 23.8 ct.; 1½ to 2-mile haul, 22 ct.; 2-mile haul and over, 21.5 ct. If the loading time could be reduced to 6 minutes per load the hauling cost per cubic yard mile would be further reduced as follows: 0 to ½-mile haul, 34.1 ct.; ½ to 1-mile, 24.5 ct.; 1 to 1½-mile, 21.7 ct.; and above that, 21.5 ct. per cubic yard mile.

Also, on a 12-minute loading basis the cost per yard for the hauls would be as follows: 0 to ½-mile, 13.5 ct.; ½ to 1-mile, 20.5 ct.; 1 to 1½-mile, 29.8 ct.; 1½ to 2-mile, 38.5 ct.; (2 plus X) miles, 44 ct. plus 22 miles.

The data in the table warrants these conclusions for we find in Job No. 2 on the ½ to 1-mile haul the cost was 22.9 ct. with an 8.7 per cent. loss of time at the pit; on the 1 to 1½-mile haul the cost was 29.4 ct., as compared with 29.8 ct. as estimated, while on the 1½ to 2-mile haul of Job No. 3 the cost was 38.4, as compared with the estimated cost of 38.5 ct. and on a 2.95-mile haul the cost was 67 ct., with a 12.3 per cent. loss of time as compared with the estimated cost of 65 ct.

It would thus appear that efficiency in team hauling and consequent low cost is largely dependent upon and might easily be secured by obtaining the maximum efficiency in loading. This problem is by no means as easy as that of the hauling for many varying conditions are encountered. The total loading and hauling cost on the various jobs was figured to provide for the shovelers actually employed and $5 per day additional for the general superintendence of a foreman or the contractor. The resulting loading costs varying from 7 ct. to 25 ct. per yard, the lower figures being too low on account of the teamsters acting as shovelers while waiting to get into the pit and the highest figures being boosted on account of an excessive amount of frost and firewater, and poor supervision. The lowest job average for loading was secured on Job No. 2, it being 9 ct. per yard. Favorable pit conditions were a large factor in producing this low figure. It would appear that for average pits 10 to 15 ct. per cubic yard should cover the item of loading by hand. Whether or not some mechanical loader would be able to reduce this item I am unable to state.

Tractor Hauling

The failure successfully to solve this mechanical loading problem contributed in a large measure towards increasing the figures I am able to present on gravel hauling by tractor.

The tractor hauling outfit used in Redwood County

*2-2½ miles. †2½-3 miles. ‡2.95 miles.

consisted of a 30-60 Holt Caterpillar Gas Tractor and a train of 7 Troy 3½-yd. reversible spreader wagons, a 50-yr. storage bin and a belt conveyor loader.

Difficulties were encountered from the very start. Considerable time was consumed in erecting the storage bin and loader. When the first train was finally loaded ready to start it was found that the tractor would not pull more than two cars over a short sharp pitch at the railway crossing on the most direct route. After some investigation and experimenting it was found that four cars could be hauled across private fields to the top of a short pitch about ¾ of a mile from the pit and that by doubling back for the remaining three cars a train of 5 cars could be made up and hauled the remaining distance of 2¼ miles. A total of 1,365 cu. yd. was hauled in this way over an average haul of 3 miles or a total of 4,125 cu. yd. miles at the average rate of 129 cu. yd. miles per day, which on a basis of $20 per day to cover the cost of operation, interest and depreciation, was at the rate of 15.4 ct. per cubic yard mile for the hauling.

From the next pit they hauled a total of 1,584 cu. yd. onto a stretch from 1 to 3.6 miles distant, making a total of 3,422 cu. yd. miles. There were no grades greater than 2 per cent. on this stretch and they made an average of 142 cu. yd. miles per day on this work, the cost being 14.1 ct. per cu. yard mile. In several days they were able to make as high as 216 cu. yd. miles, which would be at the rate of 9.2 ct. per cubic yard mile.

From the foregoing it would appear that the cost of hauling by tractor was considerably less than by teams. The advantage in favor of the tractor would have been even greater, in my opinion, had there been more power available. A 40-80 tractor would have made a much better showing. Another factor cutting down the capacity of the train was the inability of the loading equipment to supply gravel fast enough. With ample power to pull six cars and a train load of gravel always ready when the train arrived at the pit there is no doubt that the record of 9.2 ct. per cubic yard mile made on a few days could have been maintained throughout the job.

However, in tractor hauling it is essential, as I have suggested, to have a bin full of gravel ready to dump into the cars quickly when the train arrives at the pit, for the outfit cannot make any money while waiting to be loaded. A bin of from 25 to 30 cu. yd. capacity must be provided. The bin must be portable, easily transported from pit to pit. This portable feature is essential for the loading apparatus also. Unfortunately my experience in this instance does not prepare me to tell you what equipment is practical, but I can tell you that a belt conveyor and a non-portable bin is not practical for I've seen them tried and the cost of tearing down, moving and re-erecting the bin amounted to fully 10 ct. per yard of gravel handled. The belt conveyor may be successful on a level grade or a very slight incline, but when it comes to raising the gravel about 30 ft. vertically you have gone beyond the practical range of a belt conveyor. I have no definite data as to the cost of loading with this apparatus, but as nearly as I can estimate it was between 25 and 30 ct. per yard, which together with the cost of moving the bin makes a total loading cost of 35 to 40 ct. per yard.

It would seem with the proper equipment the total loading cost should not exceed 10 ct. per cubic yard. If this is possible the comparison between tractor and team hauling is very much in favor of the tractor.

Besides the cost there are other features in favor of the tactor hauling which I wish to point out briefly. First: By applying the gravel in two courses with a tractor you get your gravel rolled without additional cost and the road is ready for travel as soon as the gravel is applied instead of a month or more later as with teams. Second: By loading into a bin; thence to wagons and thence to the road you obtain an efficient mix of the materials so that instead of having one load with good gravel with a fair amount of binder followed by a load of sand with no binder and the resulting hard bump and chuck hole a few weeks later you have a gravel of uniform consistency which does not tend to develop waves or chuck holes.

Big Machine Plant

The city council for St. John, N.B., has ratified the taxation agreement made with Messrs. T. McAvity & Sons in 1914, looking to the erection of a large iron and brass foundry on the Marsh Road, immediately adjacent to the I. C. R. tracks. It is understood that the firm have recently been awarded a heavy order for munitions and that they will rush the erection of their plant in order to fill this order. The agreement calls for the expenditure of $100,000 the first year. This the firm are prepared to do? The plant that the firm have in prospect will be one of the largest in the lower provinces.

Improved Granite Block Pavements

The Evolution of the Commercial Stone Paving Block—Some of the Present Methods in Modern Highway Construction

By C. F. Knowlton*

Stone block pavements are perhaps the oldest type of street paving known. The early Romans paved streets with large irregular shaped stones, often two or three feet in depth, the joints being filled with smaller stones wedged in with mortar. The earliest type of stone pavements in this country were built with round field stone and beach cobbles, laid in sand, with joints filled with gravel. More recently quarry-split rectangular or cube paving blocks, of which there was an abundant supply in the granite hills of Maine and Massachusetts, came into prominence in the New England States. These blocks were usually about 12 inches square on top and from 8 to 12 inches in depth, laid on natural soil in a sand bed with sand joints. This made a very permanent pavement, but it was rough and uneven.

Following this, smaller blocks were used, but these also settled, when laid in a sand bed, leaving an uneven surface. About 1880 concrete foundations for street paving came into general use. The size of the blocks was then reduced, both in surface area and depth, builders figuring that with a concrete base much less depth of brick would suffice.

This line of reasoning caused them to adopt a block 4 to 4½ ins. deep, 3½ to 4½ ins. wide, and 6 to 12 long. Laid on a concrete base with cement grouted joints, this proved to be an ideal pavement and opened up an era of improved granite block paving. The engineers of some of the large cities hesitated to make such a radical change from a deep block to such a shallow block, but made concessions in favor of shallower blocks. The consequence of this was the paving cutters were obliged to cut different sizes for different localities, but the requirements were more strict as to the quality of the stone and the fineness of the cutting.

Block Sizes

In 1912, an effort was made by a committee of the officials of the large cities to standardize paving specifications and resulted in recommending a special size paving block to be called the "standard." This was not so universally adopted as was expected and as a result the paving block manufacturers are at present turning out a number of different sizes and grades of granite paving block, each known among the trade in New England by a special designation.

A block 4 to 4½ ins. deep, 3½ to 4½ ins. wide, and 6 to 12 ins. long, will require about 31 blocks to a square yard with joints not to exceed ¾ in. in width.

The "standard" size block is 4¾ to 5¼ ins. deep, 3½ to 4½ ins. wide, and 8 to 12 ins. long, cut to lay about 28 blocks to a square yard with joints not to exceed ½ in. in width.

The "N. Y. special" size block is 6 to 10 ins. long, with ⅜-in. joints.

The "Boston special" size block is 5 to 5½ ins. deep, 4 to 4½ ins. wide, and 8 to 12 ins. long, joints not to exceed ½ in. in width.

The "6-inch" size block is 6 to 7 ins. deep, 3½ to 4½ ins. wide, and 9 to 14 ins. long, cut to lay about 25 blocks to a square yard with joints not to exceed ¾ ins. in width.

*Before American Road Builders' Association, Pittsburgh.

The "city" block is 7 to 8 ins. deep, 4 to 5 ins. wide, and 9 to 14 ins. long, cut to lay about 23 blocks to a square yard with an indefinite joint.

The "track" block is 5½ to 6½ ins. deep, 3½ to 4½ ins. wide, and 6 to 12 ins. long, rather rough cut and with an indefinite joint.

In addition to these regular trade sizes, the manufacturer is often called upon for special sizes for special conditions, among which is the "durax" size. These are cubes of from 2½ to 4 ins. It is obvious that so many sizes of granite blocks leads to confusion and irregularity in method and cost of construction and in the pavement surface.

Standard Types

During the year 1915, the Granite Paving Block Manufacturers of the United States decided to confine their production of blocks to three sizes, except where specials were called for to meet some peculiar requirements, like track paving, etc. These three sies are:

The "standard" size block as given before.

The "shallow standard block," size 4 to 4½ ins. sq. and 7 to 11 ins. long, cut to lay with joints not exceeding ½ in. in width.

The "resurfacing" blocks, designed to be used for resurfacing on original foundation when asphalt, wood block, or brick pavements, are to be replaced, size 3¾ ins. to 4½ ins. wide, 3½ to 4 ins. deep, and 7 to 11 ins. long, cut to lay with joints not exceeding ½ in. in width.

These sizes and all special blocks are all cut and split by hand labor, have square edges, smooth surfaces and lay with close joints. All of these sizes may be termed "improved granite blocks."

Improved granite block, having square edges, smooth surfaces and close joints, are usually laid on a concrete foundation.

The "6-inch," "city," and "track" are considered as rough cut blocks of the old type and are laid with wide joints, generally on a gravel base and with sand or gravel joints.

No engineer should accept or specify a stone block pavement which failed to result in an even surface in every way acceptable for both horse and automobile traffic. To secure this smooth even surface, it is necessary for the engineer to require a carefully split stone block having no projections exceeding ⅜ in. from a true plane, and that the blocks be laid in the street on a properly drained sub-foundation, a substantial concrete foundation, and with close, even joints, and these joints be filled with a rich mixture of cement grout or with a bituminous filler of asphalt or pitch.

The use of the two different fillers is largely a question of prospects of future openings being made in the pavements. If frequent openings and quick repairs are necessary, the bituminous filler is more convenient and economical, openings can be made easily and the surface replaced satisfactorily without loss or wastage of blocks. Where openings are not apt to be frequent or where traffic conditions will allow the street to be closed for a period to allow the cement grout filler to properly harden, the cement filler should be used and will give a smooth surface, protect the edges of the blocks, and give better results usually than the bituminous filler.

Subgrade

A firm subgrade and a strong concrete foundation are just as essential in laying a stone block pavement as they are in laying other types of smooth pavements. It is true, however, that many grouted stone block pavements have been laid without a concrete foundation and some have been in small cities and towns where the traffic could not be considered heavy and where the sub-soil is especially good. Danger lies in the liability of the blocks to settle under heavy loads; if this occurs in the slightest degree the bond of the cement is broken and it scales off and loosens in the joints.

In this type of pavement it is necessary to use a deep "city" block and have the cement grout fill the joints their entire depth to get the necessary stability.

The cost of handling and transporting these deep and heavy blocks is nearly twice that of the small blocks and in localities far removed from the quarries it will be found that a 4-in. stone block can be laid on a concrete foundation, requiring no more excavation and less labor and cement, for less money and will give a more permanent smooth surface.

As to the construction of improved granite block pavements, I will describe the methods we used in constructing nearly a million square yards in Massachusetts and Rhode Island in the past ten years.

In excavating and preparing the subgrade, great care is taken to have the subsoil thoroughly compacted by a steam roller and hand tamps, all soft and spongy material is removed and good firm dry material takes its place, especial care being taken to see that newly filled trenches are well compacted. The subgrade is left smooth and exactly parallel with the proposed finished grade. On this subgrade a well mixed concrete base is laid 6 ins. in depth. On good undisturbed natural soil a 1:3:6 mixture is strong enough; on filled ground where underground pipes have recently been laid a 1:2½:5 mixture should be used.

Concrete Foundation

We usually lay our concrete foundation by the grouting and compression method. Many tests made show that for equal thickness, the compressed concrete is 33 per cent. stronger under a bending strain and 40 per cent. stronger under a compression test, than ordinary mixed concrete, hence under this method the thickness of a concrete foundation can be reduced to 4 or 5 ins. with perfect safety and with a considerable saving in costs.

A layer of egg-size crushed ledge stone is placed on the subsoil and rolled to the required thickness. A Portland cement grout is then poured into the stone and the stone rolled during this process until all the voids are filled and the grout flush with the surface. The grout is mixed in different proportions according to the thickness and character of the wearing surface of the pavement. One part of cement and four parts of sand is most generally used. This is mixed in a patented grout mixer operated by a gasoline engine and which is self-propelling.

The sand, cement and water are carefully measured by volume for every mix and the grout is distributed evenly into the stone through pipes long enough to cover the entire width of the foundation. Concrete foundations laid in this manner have proven very successful. They can be laid much faster than by the ordinary method and cause less obstruction to travel in the handling of materials. The surface of the concrete base is left smooth and exactly parallel with the proposed surface. Upon this we place our sand cushion. This should never be more than 2 ins. nor less than 1 in. in depth. We prefer a maximum of 1½ ins. In some cases we have used a dry mortar bed, ½ to 1 in. in depth, mixed in proportion of one cement to three or four of sand, but do not recommend it. When it sets up the pavement is too much of a monolith and is noisy. A sand cushion deadens the noise of traffic and furnishes a little elasticity to the pavement, which is essential.

Cushion

The cushion is to compensate for any irregularities in the depth of the blocks and to give a uniform bearing to the bases. In the old type of blocks the variation was 1 in. and sometimes as much as 2 ins. in the depth, hence, if shallow blocks were laid in with deep blocks, the strength of bearing would be unequal and under traffic the shallow block would be pounded down, causing an uneven surface. The improved blocks are cut with only ½ in. variation in depth and the thickness of the cushion is therefore more uniform. The granite paving blocks are laid on this sand cushion by the most experienced pavers we can find. Blocks are laid in regular courses end to end across the street at right angles to the curb. Joints are broken by a lap of at least 3 ins.

Clean ½-in. pea stone is then scattered over the surface and broomed into the joints, only enough being used to steady the blocks while being rammed. The blocks are then rammed to a firm, unyielding bed with a 60-lb. rammer or rolled with a 6-ton tandem roller until the surface is smooth and regular.

Granite paving blocks should be of medium grained granite showing an even distribution of constituent minerals of uniform quality and texture, without seams, scales or discolorations showing disintegration, free from an excess of mica or feldspar. Usually a better selection of granite can be made by reference to past performance of any particular granite from any particular quarry than to attempt to make a selection from local tests.

Where a cement filler is to be used, the granite blocks need not be cut so fine and the joints can be wider than where a bituminous filler is used. We find that blocks 4 to 4½ ins. deep, 3½ to 4½ ins. wide and 6 to 12 ins. long are most suitable for this purpose and have used them in 75 per cent. of our work.

Joint Filler

Filling the joints in the pavement is the most important part of the construction, as upon it depends the smoothness and permanency of the surface.

We seldom use a bituminous filler, as it does not protect the edges of the block as they should be. After a few years the filler is worn down in the joints and the edges of the blocks become rounded and the pavement becomes rough and noisy. Nearly all our improved granite pavements have a cement filler.

We first wet the blocks until they have absorbed all the water possible and keep them wet until the grout is applied. The grout is composed of one part of cement and one part of clean sharp sand with enough water added to make it of the consistency of thin cream. This is mixed in our self-propelling grout mixer which travels on planks placed on the pavement. The grout is kept constantly agitated until it reaches the joints and every mix is exactly alike. The grout is run directly on the surface and broomed evenly into the joints.

During this operation clean pea stone, well wet, is lightly scattered into the grout and broomed into the joints. After this grout has subsided in the joints and before the initial set takes place, the surface is again treated with a grout of the consistency of thick cream which is evenly broomed over the surface until the joints are full and flush with the top of the blocks. A rubber of wood squeegee, or scraper, is then used to scrape off all the surplus cement from the surface.

The effect of this is to leave the depressions in the block filled with cement while there is none on the projections, thus making a smooth surface. When the cement is sufficiently hardened, the surface is sprinkled from a can and a fine floor brush used to brush and smooth out all irregularities. After the cement is set, the surface is copiously sprinkled and kept wet for three or four days.

All travel is kept off the pavement for six to ten days. Plenty of water is used to wash the blocks—you cannot get satisfactory results if dirty blocks are used. The joints must be open sufficiently to allow the grout to flow in and penetrate to the bottom. The cement must not be allowed to set too quickly and in very dry weather the surface should be kept covered with wet sand for at least three days.

Expansion Joints

On a business street, we lay a felt expansion strip ½ in. thick and 6 ins. wide, along the curbstone, between the blocks and the earth. This acts to deaden the sound and prevents vibrations being carried into the buildings. Where there are car tracks in the street, the web of the rails is plastered with cement mortar flush with the outside of the head of the rail, after the foundation is laid. This allows the blocks to lay firmly against the rails and still not be affected by any slight movement of the rails.

If cars are running during the grouting operations, the shaking and vibrations of the rails may cause the blocks to "float" that is: the vibrations cause the block to shake and the fresh grout works down under the block forcing them up, a little above the head of the rails. In such cases the cars should be kept off the tracks until the grout has well set, in fact, it is desirable that cars be kept off during the whole time paving operations are going on and for six days after completion. If this is impossible, they should be made to travel very slowly.

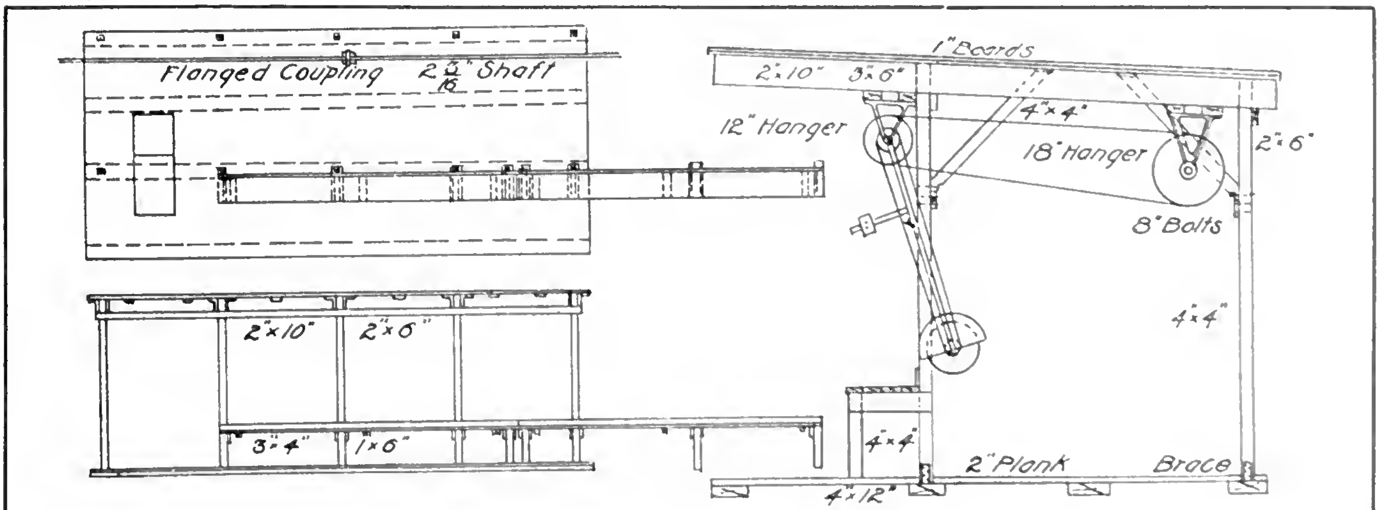
As "Eternal vigilance is the price of liberty," so it is with improved granite block pavements. Careful attention to the quality and kind of materials and constant watchfulness in putting them together are the true secrets of our success.

When you lay a pavement that is going to last forty or fifty years, you cannot afford to take any chances in its construction. You should have the best material and the most expert assistance you can get. Do not consider first cost too seriously. What does a few extra dollars amount to on the first cost of a pavement that will cost you nothing for upkeep, if properly laid, and at all times and seasons meet the demand of all classes of traffic? The cost of improved granite block will vary a great deal in different localities.

Making Forms for Concrete Work in a Model Shop Built in the Field

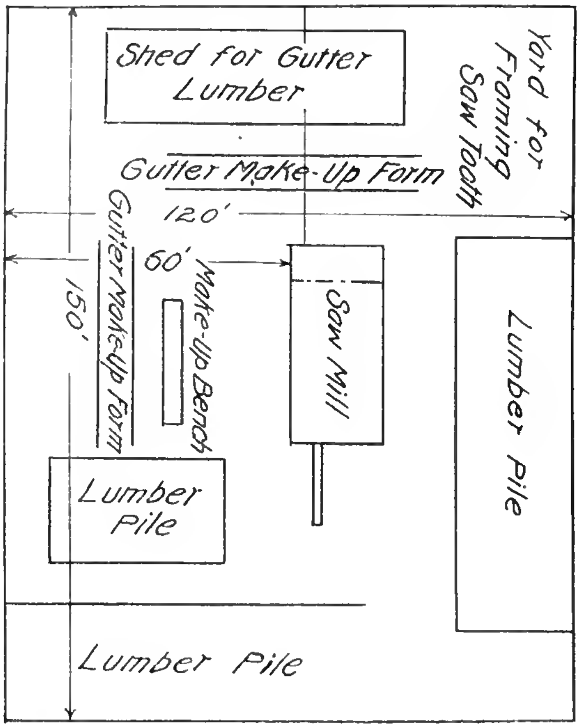
REINFORCED concrete enjoys probably the largest field of endeavor today of all the building materials. All sorts of public and private buildings, public works, dams and retaining walls, etc., are now almost universally built of either massed or reinforced concrete. With the increasing use of concrete and the complexity of design to gain a more artistic effect in the architectural features, the problem of the design and construction of the necessary forms becomes a most intricate problem. The carpentry work of form making is now a large factor in reinforced concrete construction, both as to cost and in the quality of the finished work.

For a contract of any considerable size, a large carpenter force of skilled mechanics is necessary to cut, shape and place the forms in advance of the concrete



Plan, elevation and enlarged section of an open mill.

gangs. If the design is at all complicated, the forms become ever so much more so, and require a great deal of skill in making and setting them. Of late years any contractor building concrete structures, to save

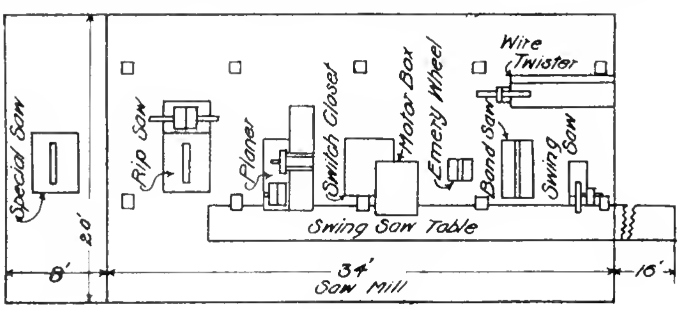


Layout plan for yard for form making.

labor almost invariably has, on the ground, some arrangement for preparing forms and other lumber and timber details—usually a small carpenter's shop, or an open planing mill, set up in charge of a competent carpenter. All lumber used in the construction of the work, besides that for scaffolding, studding, bracing, etc., is repared in this shop.

The carpentry work of form building is such a large item in re-inforced concrete construction that the handling of this work to the best advantage means working up the lumber on power saws and assembling it on special benches, made for the purpose, to obtain the maximum efficiency and lowest cost factors. Mr. S. T. Koon, a contributor to the "Cement World," describes the standard shop of a large Boston concrete company, who use the plans, as shown, on most of their jobs, enlarging them whenever necessary.

They handle all form-making by power machinery, right on the job, employing for the purpose several power saw rigs and portable wood-workers. The cuts



Plan of mill showing arrangement of machinery.

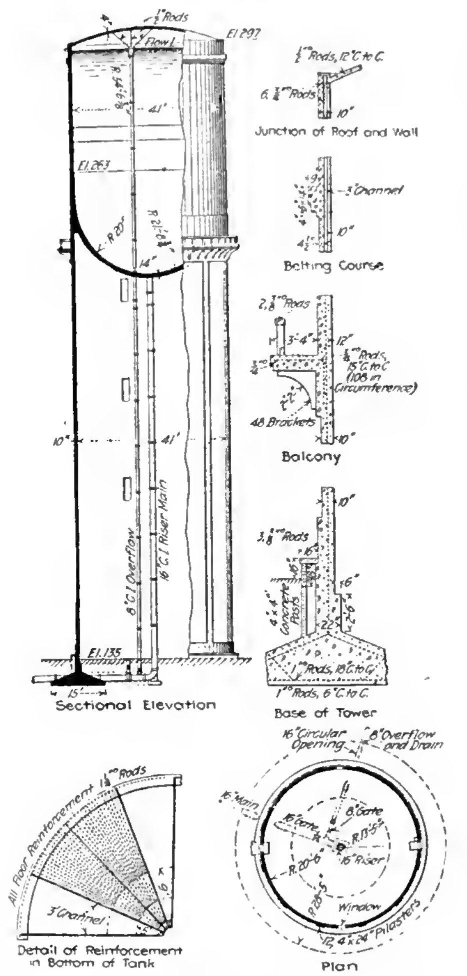
show a standard set of their plans, which can be extended, if necessary, to suit any requirements. The location of lumber in relation to the shop is shown. The shed measures 34 ft. x 15 ft. 6 in., while an extension of the saw bench carries the length 16 ft. further. An over-hanging section of the roof is 7 ft., bringing the total length of the roof to 31 ft., with the total length of the saw bench 57 ft.

Such shops can be quickly and economically built by any large contracting firm in the cement business, and would save considerable time, expense and labor, and prevent hold-ups of the concrete gang, due to carpenters being behind time. The principal tools necessary would be a swing saw, band saw, rip saw, and planer, with any special machinery that would be deemed advisable for the particular contract. Such machinery could be driven from a central line shaft run by electric motor where electric current is cheap and convenient, or by a gasoline engine, if the plant is isolated.

The benefit of such a system is, that forms are generally cut truer and more uniform resulting in a smoother face on the concrete, carpenters are kept busy all the time in spite of other delays and they are generally able to keep the forms so well in advance as to exclude the possibility of a hold-up on their account. Slack periods alternating with rush periods are done away with; work becomes a steady operation from start to finish; scientific management of the shop and the materials, after carefully planning their location relatively to the wok, eliminates any excessive handling of material and reduces the carpentry bill for form-making to a minimum.

World's Highest Reinforced Concrete Water Tank

What is claimed to be the highest reinforced concrete water tank in the world, was recently built for



Plan, elevation and sections of world's highest reinforced concrete water tank.

the city of Middleboro, Mass., and is described by the Blaw Steel Construction Co., Pittsburg, whose forms were used in the construction, as follows:—

Concrete was chosen for this tank and the tower supporting it for several reasons. The cost of a steel tower and tank would have been less, but the life would be short and the repairs, painting, etc., would also cause more expense than a concrete tank. In addition to this, the concrete could be finished in an artistic and attractive way and as designed and built is very pleasing from an architectural standpoint.

The bare surface of the tower is broken up by twelve 4 by 24-inch pilasters and at the junction of the tower and the tank, 108 feet above the ground, is a balcony of reinforced concrete with bracket supports. The details shown here give an idea of the design and the reinforcing that was used.

The tank itself is of the same inside diameter as the tower, which is 41 feet, and will have a depth of water in it at the center of 59 feet when full. The bottom of the tank is hemispherical, which is the first time that this type of construction has been attempted with concrete tanks.

Blaw steel forms were used for the outside of both the tank and the tower. They were justified because of the reduction in time and expense that attended their use and they also formed a dense, smooth surface that required very little finishing. Their forms as used on the tank and tower were made as two rings, each 4 feet wide. Wooden forms were used on the interior.

The Larger Use of Canadian Timber

Toronto Architect Urges the Use of B. C. Fir in Preference to U. S. Pine; and Canadian instead of U. S. Architects

MR. A. R. DENISON, of Denison & Stephenson, Architects, Toronto, recently addressed the Lumbermen's section of the weekly meeting of the Toronto Board of Trade, on the importance of Canadians using Canadian lumber whenever possible, and for closer co-operation between architects, lumbermen and owners of buildings under construction for the prompt settlement of accounts for supplying material.

Separate Cheques for Lumber Bills

Mr. Denison recited a specific case of misunderstanding between owner, contractor and lumberman, wherein the lumberman did not receive his proper compensation, and suggested as a remedy that the owner pay the lumberman direct. The speaker went into this situation more in detail and finally asked why something should not be done to put the whole situation beyond any peradventure. It seemed to him this would be quite easy if the interested parties would get together. His idea was that an arrangement should be made in writing between the proprietor and the contractor at the time of signing the contract, requiring the contractor to submit to the proprietor a summary of the lumber to be used in the building; and further, that a statement should be rendered to the proprietor from time to time during the continuance of the work, and that the proprietor should be required to draw separate cheques in favor of the lumber merchant as each certificate became due; the lumber merchant to be subject to a drawback clause of 80 per cent. in the contract and also to have a claim upon the 20 per cent. retained by the architect; a duplicate statement to be rendered to the architect if required. He believed that a plan of this sort, in which the owner, the architect and the contractor co-operated would remove a great deal of trouble. If the lumbermen would take it up and pass a definite resolution in regard to it, asking the architects to co-operate, he would put the matter before the architects, and felt pretty sure that they would fall in line.

Use Canadian Materials

Mr. Denison is a strong advocate of using Canadian woods wherever possible. He referred to the fact that the original Toronto city by-law made Georgia pine the basis for timber construction purposes. He had asked the city architect to use B. C. fir for such purposes and had simply been told that it was not allowed by the by-law and could not be done. This was a mistaken view of the city architect. He should have been interested solely in the strength of the timbers used, not the variety of timber. Although he expressed this opinion to the city architect at that time, the reply he received was simply that Douglas fir was not allowed by the by-law and he would not permit it to be used.

However, Mr. Denison, against the advice of the city architect, made preparations for building two houses, one to be built of Douglas fir and the other of Georgia pine, and was hailed before a judge, who permitted him, after seeing tests on the two timbers, to go ahead. Tests were made upon both Georgia pine and Douglas fir. The Georgia pine selected was 8¼ in. x 19¾ in. x 18 ft. long. The Douglas fir stick was 8 in. x 19¾ in. x 18 ft. long. The tests were made at the School of Practical Science, Toronto. The Georgia pine stick broke off at 43,550 lbs., and the Douglas fir stick split lengthwise but did not break at 55,320 lbs. From that day on they had been allowed to use Douglas fir.

Douglas Fir

Douglas fir was unquestionably the best wood they could get for construction purposes. It was also the strongest wood and it was one of our own native woods. He urged that lumbermen, architects and contractors should put forth every effort to use Canadian materials on Canadian buildings. Mr. Denison referred to instances of failure that he had come across in using Geogia pine. He had been obliged to take out at least six sticks of long leaf pine within five years from the time they were put in, because of dry rot. There seemed to be a failure in a certain percentage of Georgia pine stock. It really required an expert to know Georgia pine. In fact, he had known men who called themselves experts, who differed with one another in deciding whether certain southern timbers were long leaf pine or not. He had always found that Georgia pine checked to a greater extent than Douglas fir. It was also much more combustible, as it was full of gum and was easy to set on fire.

The speaker urged that lumbermen commence at once upon an effort to encourage the use of Canadian woods. The Dominion Government had taken a step in this direction by passing an order that nothing but Douglas fir was to be used in the construction of public works. If an effort were made along this line and followed up vigorously it would make a great difference to Canadian lumber manufacturers. He understood that during the last year over four million dollars worth of Georgia pine had been imported into Canada. In normal times he understood that the amount was far greater.

Employing U. S. Architects

Underneath all this was a question of vital importance to Canadians, frequently one would see a company with a name that would lead one to suppose that it was a Canadian company, who in the construction of large buildings employed U. S. Architects. The U. S. architects would naturally specify U. S. brick, U. S. wood, etc. Every lock, every fitting, the plumbing, everything throughout the building would be brought in from the United States because the architect would be getting his percentage on every one of these items. Canadian architects would not be allowed to put up buildings in the United States. Canadian dentists, veterinary surgeons, lawyers, doctors, all classes of professional men, except the architects were protected against this sort of thing. Moreover the brick-layer and the carpenter were also protected in Canada to a certain extent by the alien labor law. In this way the U. S. firms were cutting both the lumbermen and the architect out of their own business. In order to carry out this kind of work the contractor who wanted to make use of a U. S. architect had no trouble at all. He simply obtained blue prints and had them put through the customs at their cost, paying in duty a nominal sum of a few dollars. Under present conditions there was no escaping from this situation, but he believed that the architects, on a short time, would make an effort to have the law enforced more fairly in connection with the importation of plans.

After an interesting discussion on Mr. Denison's remarks, Mr. Reid, the chairman, stated that together with M. W. J. Hetherington, he would draw up and present at a later meeting of the board a resolution upon Mr. Denison's proposal, and he hoped that in the near future something definite would be forthcoming.

Activated Sludge Sewerage Experiments*

THE Sanitary District of Chicago began experiments with the activated sludge process of sewage treatment on Stockyards and Packingtown sewage in April, 1915. The operation on the fill and draw plan was carried on in two galvanized iron tanks, each holding approximately 200 gal. of sewage. These experiments were continued well into the cold season, being discontinued when the contents of the tanks froze solid. Certain observations were made, which can be explained by the effect of low temperatures upon the process. These observations were substantiated on the larger 4 unit installation of the Sanitary District designed to treat from 30,000 to 100,000 gal. on the continuous flow basis daily. This installation was put into operation early in 1916 and is under the direction of Langdon Pearse.

The changes of the nitrogenous constituents during the aeration process have been carefully studied. Our experience has coincided, so far as I am aware with the experience of other observers. During the warmer season a reduction of the free ammonia to about 1 or 2 p.p.m., and an increase of the nitrites to 5 or 10 p.p.m., indicates complete oxidation and clarification. This ceased to be the case, however, when colder weather set in with the small galvanized iron tanks, which were easily affected by changes in temperature in the air. Absolute stabilities were reached in cold days with the free ammonia actually increasing several hundred per cent, and with little, if any, change in the nitrites and nitrates. The reduction of the organic nitrogen was just as marked as in summer. Clarification was very satisfactory. The results I speak of are those noted when the effluent showed a relative stability of 100 or thereabouts. With the small galvanized iron tanks, in which the warm sewage quickly chilled, it took a considerably longer time in the cold weather to obtain such a high stability, but the chemical results were consistently as noted.

It is clear that in such cases the mechanical features of the process outweighed the biologic features. The highly putrescible colloids have simply been whipped out of suspension by the continuous agitation. Repeated observations indicate that the mere mechanical removal of the colloidal matter from sewage brings about an improvement far out of proportion to the actual percent of substance removed. There is no doubt, however, that there is some biologic activity even in a liquid near freezing, otherwise, we could hardly account for the persistent increase in free ammonia. We further noted various active protozoa, such as infusoria and trachelomonas in the sludge at all times. More highly developed animal or plant organisms were not found. Our work indicates that the temperature of the liquid treated will be a controlling factor. On a large scale temperature changes will probably be much lower than on the very small scale of 200-gal. steel tanks exposed to weather.

During the cold weather we had no ready chemical index to go by, although the regular routine tests of long duration were available. The removal of the colloidal matter was the only immediate indication of accomplished oxidation. This forced us to determine regularly the turbidity of the settled aerated sewage. Used with the methylene blue putrescibility test, a fairly definite working relation can be established. The tabulation of a large number of results obtained shows that the stability is 100 with turbidities of 10 p.p.m. or less. With a turbidity of 15 p.p.m., the relative stability varies usually between 50 and 100. With turbidities above 15, the quality of the effluent shows rapid deterioration. At turbidities ranging from 20 to 25 the stabilities are usually below 50. To compare turbidities above 25 p.p.m. with stabilities appears unsafe. Such stabilities are without exception very low. The relation spoken of is bound to vary with sewages of different character. Recently with the advent of warmer weather, the nitrites are again picking up in the effluent, and no doubt our ammonia index will again serve the purpose. The determination of other constituents, such as the organic nitrogen albuminoid ammonia, permanganate oxygen consumed, chlorine and the bacterial content, are merely of scientific interest. They are not essential for a routine control. This

*Extracts of a paper by A. Lederer before the American Chemical Society.

holds good to a certain extent for the dissolved oxygen, but it is quite conceivable that the rate of de-oxygenation at a given temperature can be made to serve as an index of the degree of stabilization accomplished. The quantity of the settling suspended matter in the final effluent merely indicates the efficiency of the settling process, and has nothing to do with the activated sludge process proper. Packingtown sewage completely oxidized by the activated sludge process is clear with a slightly yellowish tint barely noticeable in small bulk.

Sturtevant Contracting Set

The following illustration shows a new adaptation of the Sturtevant gasoline generating set. These sets are intended to be used in direct connection with lighting and power circuits and not through storage batteries, although they may be so arranged if desired. A very sensitive governor control, together with other fineness in design of engine and generator, insure a constant voltage through wide variations of load. The unit consists of a direct current electric generator direct connected to a gasoline engine. A switchboard and gasoline tank is also included. A special type of disc fan is mounted on an extension of

Sturtevant Gasoline Contracting Set.

the generator shaft and arranged to blow air through a cellular type radiator. All of this apparatus is mounted upon two channel irons and the engine generator and switchboard are covered by a sheet metal housing, similar to an automobile hood. The engine is of the four cylinder, water cooled, vertical type with either four or six cylinders, according to the size of the unit. Three sizes of these sets are built, 5 kw., 10 kw., and 15 kw. capacity capable of lighting 200, 400, and 600, 20 candle power tungsten lamps. Both engine and generator are capable of operating under an overload of 25 per cent. for two hours.

Trade Inquiries

Names and addresses may be obtained from the Department of Trade and Commerce, Ottawa.

362. **Steam-electric power plant apparatus and engineering specialties.**—A gentleman who intends visiting New Zealand during the coming summer is desirous of securing the agencies of Canadian engineering manufacturers of steam-electric plant apparatus and engineering specialties, and is desirous of receiving full technical description of apparatus together with illustrations, weight of apparatus, shipping weight, and weight of heaviest piece, and over-all dimensions. Present prices either f.o.b. Canadian or American port or c.i.f. New Zealand port.

384. **Glass.**—An English firm of glass importers inquires for Canadian exporters of glass for lighting purposes and table use, to replace supplies formerly imported from Germany, Austria and Belgium.

377. **Brassed rods.**—A Birmingham bedstead manufacturer is open to purchase cased brass rodding. Samples on file at the Department of Trade and Commerce. Prices must include delivery Birmingham or Liverpool.

Personal

Mr. C. Dufort, architect, has removed from 198 St. Catherine Street West, to 195 St. Catherine Street East, Montreal.

Major Howard Dinnel Bodwell, of the 2nd Pioneer Battalion, was recently wounded in action. Major Bodwell was an engineer in civil life in Vancouver, and saw active service in the South African campaign.

Mr. J. Quail, until recently sales' engineer of the Manitoba Bridge & Iron Works, Winnipeg, has taken up new duties with the Canadian Bridge Company, Walkerville, Ont., as manager of their Winnipeg office.

Mr. George D. Mackie, City Engineer-Commissioner, Moose Jaw, Sask., has been appointed a member of the Royal Commission recently formed to enquire into and report on the work of the Provincial Highways Department of Saskatchewan carried out by that body from 1913 to 1916.

Obituary

Mr. D. Gladstone, head of the Fort William Granite Works, recently died at his home in Fort William. Mr. Gladstone, who was a prominent business man of Fort William, had been in ill health for some time.

The death occurred recently in England of Mr. Harold A. Copp, formerly head of the Copp Stove Works of Fort William. Mr. Copp has been an active business man and was a widely-known philanthropist, taking special interest in Y. M. C. A. work in Fort William.

At a largely attended meeting of the Quebec branch of the Canadian Society of Civil Engineers, held on the 17th inst., a resolution was passed expressing sympathy with the relatives of their late colleague, Mr. L. B. Verge, C.E., in his untimely demise, and with Mr. W. D. Baillarge, C.E., on his recent bereavement.

The death occurred recently of Mr. Albert C. Smith, president of the Smith Foundry Co., one of Fredericton's most prominent business men. Besides being president of the Smith Foundry Company, he also acted as mechanical superintendent of the plant, and had been directing operations in munition work of both the day and night crews. His death was caused by pneumonia contracted during a recent fire in the company's plant.

The death occurred recently of Dr. W. F. King, Chief Astronomer of Canada and Commissioner for the Survey and Marking of International Boundaries, at the Observatory residence, Ottawa. The late Dr. King was born in England in 1854, came to Canada at the age of eight, and entered the Dominion Government service as Assistant Astronomer on the North American Boundary Commission in 1872. In 1886 he was made Chief Inspector of Survey, and in 1890 Chief Astronomer of the Department of the Interior.

The Halifax Electric Tramway Company, who are constructing a gas plant at Halifax, are also calling tenders for the erection of a by-product building, cold storage building, and for elevating and conveying machinery in connection with the same.

Mainly Constructional

East and West—From Coast to Coast

Building outlook in Calgary for the coming year, according to R. G. Dun & Company, looks particularly bright.

The Alliance Power Company, Limited, has recently been incorporated in Edmonton, Alta., with a capital of $250,000.

Building operations in the city of Quebec continue active during the last week. Permits amounting to $63,060 were issued at the city hall.

It has been decided to rebuild the isolation hospital on Sandy Point Road, St. John, N. B., recently destroyed by fire. The new building will cost $15,000.

The work of constructing the joint sewerage system of the villages of New Toronto and Mimico, is in full swing. A big effort is being made to have the system ready for use this year.

The Municipal Concrete Construction Company, of Ingersoll, have placed an order with Wettlaufer Bros. for two heart-shaped, traction paving mixers, and one tilting drum, heart-shaped mixer.

The Board of Control of the city of Toronto have refused the request of the T. Eaton Company to allow them to place the footings of their new building beyond the street line of Terauley Street.

The plant of the Union Cement Company, Owen Sound, who are working on a 50,000 barrel contract for the city of Toronto, recently sustained damage by fire. Reconstruction work will begin at once.

Messrs. Barott, Blackader & Webster, architects, Montreal, are preparing plans for a large moving picture theatre to be erected on Sherbrooke Street, Westmount, for the Imperial Theatre Company.

Following the consideration of a large number of tenders, the city of Kingston have awarded the contract to Wettlaufer Bros. for one heart-shaped traction paving mixer, with boom and bucket attachment.

Work on the Toronto-Hamilton highway in the Port Credit district is progressing rapidly; a part of the road will be closed temporarily to traffic in order that the railway for hauling cement and material may be laid.

Sackville, N. B., has just finished one of the most successful clean-up and paint-up weeks in its history. The usually attractive little town has been rendered much more attractive by the renovation it has received.

The work on the new Great Northern depot at False Creek, near Vancouver, is being rapidly pushed forward by the contractors, Grant, Smith & McDonnell. Pile driving has started and concrete work on the piers is expected to be under way shortly.

Interned alien enemies within Canadian territory are at present employed in building good roads through the Canadian Rockies. Camps are located at several points in Alberta and British Columbia, and so far the aliens are doing valuable productive and development work, as a return for the care being taken of them during the present period of stress.

As a result of the determined fight of John Allen, member for West Hamilton, it is believed that the government may agree to give a substantial special grant for the construction of a high level bridge to link up Hamilton with the Toronto-Hamilton highway and do away with the objectionable steep grades involved in the present plan. The bridge, which will be partly outside the city limits, would benefit other places as well as the city.

A provisional school in military engineering has been authorized for the benefit of the civil engineers in Ottawa at the request of the Ottawa branch of the Canadian Society of Civil Engineers, and has been largely attended by the civil engineers of that city. Colonel Maunsell, Director General of the Engineer forces of Canada, assisted by Lieutenant Attfield, and Sergeant-Major Innes, have charge of instruction.

St. Vincent's High School for Girls, St. John, N. B., which is to be built in that city under the direction of Bishop LeBlanc, will be one of the largest and most up-to-date school buildings in the province. The building will be 107 by 130 feet, three storeys in height. There will be twelve classrooms, besides chemical and physical laboratory, domestic science room, recreation room, assembly hall, gymnasium, swimming pool and shower bath.

The will of the late Robert Davies has been filed for probate, and shows in summary—real estate $896,898, money secured by mortgages $14,045.42, book debts $36,928.09, securities for money, life insurance, cash in bank, $121,059.08, bank and other stock $24,000. The real estate comprises extensive properties throughout different parts of the city. For the Don Valley Brick Works, no amount has been inserted in the schedule. The title to this property is in litigation and no value can be placed upon it until the litigation is terminated.

The city of St. John, N. B., is now revelling in the possession of one of the finest post offices in eastern Canada. The removal from the old to the new building took place a few days ago. The new building occupies a site on the eastern side of Prince William Street, almost opposite the old building and facing the harbor. The general entrances are on Prince William Street, while the mails enter from Canterbury Street in the rear. The front of the new building is of granite and freestone, ornamented with large columns, which give it an imposing appearance.

A large deputation of public men, residents of Niagara Falls and Stamford, will go to Ottawa shortly to interview the Department of Railways and Canals and ask that body to give its official approval to the plan to make the proposed Hydro-electric power canal navigable between Chippewa Creek and Niagara Falls, a plan which, if successful, is expected to make Niagara Falls the leading industrial city of the Niagara peninsula, also converting it into a lake port. The plan is to make the canal 50 feet wide and 16 feet deep, large enough to accommodate lake steamers.

Mr. Justice Weir has given judgment in the Superior Court in favor of C. Dufort and J. T. Decary, architects, who claimed $1,250 from Carl Rosenberg as fees for the preparations of certain plans they drew up on defendant's order in May, 1912. The defendant pleaded that as he had not utilized the plans he was not bound to pay for them. To follow them would have made the building he wished to construct too costly. Therefore he had to obtain new plans more in accordance with a building of his means. "All the same," ruled the judge, "you must pay for the first set of plans that you ordered made."

The entrance piers at the graving dock at St. Joseph de Levis have been completed, and work on the structure is beginning to take a tangible form. Up to the present the work has been rather of a preparatory nature, but the entrance pier is completed and the excavations for the dock itself well begun. The dock, when completed, will be 1,150 feet long, 120 feet wide at base, and 144 feet wide at top. It will be divided into two sections, the inner section 650 feet long, enclosed by a floating gate weighing 600 tons, the outer section 500 feet long, built with a rolling caisson gate of 650 tons. The structure will be concrete, faced with granite. Crib work will take 7 million feet of British Columbia fir.

St. George, Que.
Work is about to start on the erection of a store for J. Gagnon, estimated to cost $10,000. Tenders will not be called. Architects, Berube & Frere, St. George, Que. Brick and frame construction.

Toronto, Ont.
R. D. Kilgour, 45 Willcocks Street, has had plans drawn for a residence to be erected at High Park Gardens. Brick construction. Approximate cost, $12,000.

J. F. Alexander, 8 Temple Avenue, has commenced the erection of a duplex residence, estimated to cost $7,000. Brick construction.

C. E. Tyler, 85 Cumberland Street, has started work on a residence at 71 Forest Hill Road, and will let smaller trades about the end of the month. Brick construction. Approximate cost, $7,500.

E. Taylor, 162 Delaware Avenue, has commenced the erection of apartments at 29 Breadalbane Street, estimated to cost $15,000. Brick and stone construction.

Residences

(Continued from page 49)

of a Rectory. Pastor, Rev. H. B. Ashby, 914 William Street.

Middleton, N. S.
A. P. Dodge is considering the erection of a double tenement, at an approxmiate cost of $3,000. Concrete block construction.

New Glasgow, N.S.
W. H. George, Castle Building, Queen Street, Ottawa, is preparing plans of a residence for J. H. St. Claire, M.P., New Glasgow, and will call for tenders shortly. Brick and stone construction. Approximate cost, $11,000.

Niagara Falls, Ont.
Simon Larke, Main Street, Niagara Falls, N.Y., is preparing plans of a residence to be built for Albert Walterhouse, Morrison Street. Approximate cost, $4,500.

Northampton, N.B.
H. H. Smalley is building a bungalow by day labor. Estimated cost, $3,00.

Ottawa, Ont.
A. E. Shaver, 45 Powell Avenue, is preparing plans of a residence to be built on Findlay Street at a cost of about $6,500. Brick, stucco and stone construction.

T. J. Somerville, 28 Waverdley Street, has had plans drawn for two double residences to be built at an approximate cost of $7,000. Brick veneer and stone construction.

A. Levinson, 96 Blackburn Avenue, is considering the erection of a residence on Murray Street, to cost about $5,000. Brick veneer construction.

The erection of a residence is being considered by A. E. Thomas, 155 Sunnyside Avenue. Estimated cost, $4,500. Brick veneer construction.

Plans have been prepared for two residences to be built for A. E. Shaver, 45 Powell Avenue, at an approximate cost of $3,500 each. Stucco and brick veneer construction.

E. L. Parent, 387 Booth Street, is about to commence alterations to a residence, estimated to cost $3,000. Brick veneer and concrete construction.

Robert Christie, 152 Bell Street, has prepared plans for a residence to be built on Sunnyside Avenue at an approximate cost of $4,000. Double brick veneer construction.

A. E. Shaver, 45 Powell Avenue, has drawn plans for a residence to be built on Broadway at an approximate cost of $6,000. Stucco and brick veneer construction.

Paisley, Ont.
J. A. McArthur is preparing plans of a residence to be built on Queen Street, at an approximate cost of $3,500. White brick and concrete construction.

Quebec, Que.
P. Villeneuve, 241 Prince Edward St., contemplates the erection of a residence, and will prepare plans. Estimated cost, $6,000. Brick, stone and concrete construction.

Felix DeLisle, 129 Hermine Street, has commenced the erection of an addition to his residence. Estimated cost, $3,500.

Work has been started by Wilfrid Legare, 3 d'Argenson Street, on the erection of a residence, estimated to cost $4,000. Brick, frame and concrete construction.

Jules Dorion, 139 Fifth Street, has commenced the erection of a residence on Third Avenue, Limoilou, estimated to cost $3,000. Brick construction.

E. Rochette, Bourlamarque Avenue, has started work on a residence, estimated to cost $6,000. Brick and concrete construction.

Sarnia, Ont.
E. E. Corey, 203 Brock Street S., will shortly start work on four residences on Campbell Street. Frame and concrete construction. Estimated cost, $5,000.

St. Catharines, Ont.
A. E. Nicholson, architect, Queen St., will receive tenders until May 8th for the erection of a residence for A. H. Wallace, 97 St. Paul Street. Estimated cost, $10,000.

St. Remi D'Amherst, Que.
Paul Thomas proposes to erect a residence at a cost of about $3,000.

Stayner, Ont.
Tenders will be received until May 8th for the erection of a residence for T. A. McDonald. Architect, John Wilson, Collingwood, Ont. Brick construction.

Toronto, Ont.
Plans have been drawn for a pair of residences to be erected on Gillard Avenue by J. R. Gifford, 190 Pape Avenue. Brick construction. Approximate cost, $4,200.

H. D. Lang, 605 Traders Bank Building, has commenced the erection of a pair of residences on Keewatin Avenue, estimated to cost $10,000. Brick construction. Various trades will be let.

C. Caldwell, 583 Carlaw Avenue, is building a pair of residences on Kent St. Brick construction. Estimated cost $6,000.

Plans have been prepared for a residence to be built on Westmount Street by W. Colwell, 179 Delaware Avenue. Smaller trades will be let. Brick construction. Approximate cost, $3,500.

The City Home Limited, care of G. H. McLaughlin, 48 Hogarth Avenue, have commenced the erection of a pair of residences estimated to cost $5,000. Smaller trades will be let. Brick construction.

A. Milne, 66 Lamb Avenue, has commenced the erection of a residence, estimated to cost $3,200. Smaller trades will be let. Brick construction.

Work has been started by J. Meldrum, 213 Quebec Avenue, on the erection of a residence, estimated to cost $3,000. Smaller trades will be let. Brick construction.

F. Samlow, 3 Muir Avenue, proposes to build a pair of residences on St. Helena Avenue, and has had plans drawn. Brick construction. Approximate cost, $3,600.

N. Mills, 349 Palmerston Boulevard, has commenced the erection of a residence on Ward's Island. Frame construction. Approximate cost, $4,000.

J. Carlisle, 36 Pacific Avenue, has commenced the erection of a residence on Evelyn Crescent, estimated to cost $3,200. Smaller trades will be let. Brick construction.

N. Hicks, 612 Delaware Avenue, is building two pairs of residences estimated to cost $12,000, and will let smaller trades. Brick construction.

Plans have been prepared for three residences to be built by Cox & Cummings, 2118 Queen Street E. Brick construction. Approximate cost, $6,600.

Westmount, Que.
J. Sawyer, 407 Guy Street, has prepared plans of a residence for the Christian Brothers, 360 Clark Avenue. Brick and concrete construction.

Windsor, Ont.
J. C. Pennington, La Belle Building, has plans in hand for a block of four family flats to be built on Sandwich St., at an approximate cost of $10,000. Brick veneer and concrete construction.

S. C. Robinson, Devonshire Road, Walkerville, is having a bungalow built on Dougal Avenue by day labor under supervision of R. Wescott, 55 Oak Avenue. Frame and concrete construction. Approximate cost, $3,500.

CONTRACTS AWARDED

Belmont, Ont.
The general contract for the erection of a brick bungalow for A. W. Beattie has been let to Turner Brothers, Belmont. Approximate cost, $5,000.

Gananoque, Ont.
The general contract for the erection of a residence for Richard Johnston has been let to Mitchell & Wilson, Market Street. Brick construction. Approximate cost, $3,000.

Gosfield Township, Ont.
The general contract for the erection of a residence for W. Jackson, Concession 8, has been awarded to Joseph A. Jackson, Cottam. Brick veneer construction. Approximate cost, $3,000.

Hamilton, Ont.
C. H. McKay, Lister Building, has let the general, masonry, carpentry and roofing contracts for the erection of a residence to McKay Brothers, Lister Building. Brick and concrete construction. Approximate cost, $3,000.

Work has been started on a residence for E. A. Mark, 8 John Street N. The general contract, masonry, carpentry, steel work and roofing have been awarded to G. E. Mills, King Street E. Estimated cost, $5,000.

W. J. Whitfield, 224 Main Street E., has let the general contract, masonry, carpentry and roofing for alterations to a residence to J. J. Giles, 124 Grant Avenue. Approximate cost, $3,000.

E. A. Seymour, 65 Fairholt Road, is building three residences on Cumberland Avenue for F. McNiven. The contract for heating and plumbing has been let to P. A. Moore, 939 King Street E. Approximate cost, $2,000 each.

The general contracts, masonry, carpentry and roofing for the erection of two residences for J. F. Bethune, 57 St. Clair Avenue, have been awarded to James McNaught, 177 Wilson Street. Approximate cost, $3,600.

Kingston, Ont.
The general contract for the erection of a residence for Samuel Green, 74 Brock Street, has been let to Douglas & McIlguham, 510 Brock Street. Brick and stone construction. Approximate cost, $5,000.

London, Ont.
The general contract for the erection

of a residence for Mrs. F. C. Vrooman, 21 Askin Street, has been let to S. Stinchcombe, Pipe Line Road, and work has been started. White brick and concrete construction. Approximate cost, $3,000.

Middlemiss, Ont.

W. Saunders, Dutton, Ont., has been awarded the general contract for the erection of a residence for Alexander Battin, Middlemiss, and will shortly start work. Brick and concrete construction. Estimated cost, $3,000.

Montreal, Que.

The contract for roofing required in the erection of a residence for D. C. G. Higginson, 3435 Park Avenue, has been let to Campbell, Gilday Company, 793 St. Paul Street, and the electrical work to Electric Repair & Contracting Company, Limited, 317 Craig Street West. Remainder of work by general contractors.

The contract for roofing required in the erection of a residence for E. W. Herring, 2 McGill College Avenue, has been awarded to Campbell, Gilday Company, 793 St. Paul Street W., and the electrical work to the Electric Repair & Contracting Company, Limited, 317 Craig Street W.

J. C. Perron, 669 Querbes Street, has commenced the erection of a residence and garage, and has let the contract for foundations and masonry to F. X. Cusson, 2200 St. Lawrence Boulevard, the carpentry to J. B. Beaumont, 2480 Waverley Street, brick work to S. Rochon, 470 Outremont Avenue, and roofing, heating and plumbing to J. E. Blanchard & Son, 2168 St. Lawrence Boulevard.

Mrs. C. M. Hays, 694 Mountain St., has awarded the general contract for the erection of a residence and garage to J. H. Huntchison, 64 St. Antoine St. Brick and concrete construction. Approximate cost, $5,000.

Montreal West, Que.

The general contract for the erection of a residence for J. A. Elder, 108 Strathearn Avenue, has been let to W. H. Payne & Company, 62 Westminster Avenue N. Estimated cost, $5,000.

Ottawa, Ont.

C. Sutherland, 460 McLeod Street, has let the contract for masonry required in the erection of a residence on Carling Street to Beattie & Davidson, Renfrew Avenue. Other contracts will be let later. Approximate cost, $7,500.

J. Y. Caldwell, Kirchofter Avenue, has commenced the erection of two residences on Carleton Avenue, and has awarded the contract for electrical work to P. Ackroyd, 416 Bank Street. Estimated cost, $3,500 each.

Quebec, Que.

The general contract for the erection of a residence for Lucien Gaboury, 404 St. Valier Street, has been let to V. R. La Montagne, Quebec Railway Building. Brick construction. Approximate cost, $4,00.

The contract for roofing, heating, plumbing and electrical work required in the erection of a residence for Mde. H. R. Dussault, 163 Fifth Street, has been let to A. Lapointe, 74 Sixth Avenue, Limoilou.

N. Jobidon, 110 Fifth Street, has commenced the erection of a residence for Robert Jobidon. Brick construction. Approximate cost, $8,00. Tenders on roofing, plumbing and electrical work are now being received by the owner.

St. Marys, Ont.

Frank H. Smith has awarded the general contract for the erection of a residence on James Street to W. Heuther, the carpentry to Stafford & Henderson, Queen Street W., plastering to C. Hammond, painting to F. Willard, Water Street N., and heating and plumbing to Cline & Wellington Steet. Approximate cost, $4,000.

Toronto, Ont.

The contract for masonry required in the erection of a residence for Mrs. O. G. Palm, 133 Roxboro Street E., has been awarded to Gordon Brothers, 1 Delisle Avenue, and the carpentry to Madden Brothers, 552 Adelaide Street W. Estimated cost, $14,000.

James Allan, 30 Castlefield Avenue, has been awarded the general contract for the erection of a residence for T. A. Gibson, 423 Walmer Road, and will let smaller trades. Estimated cost, $6,500.

Roberts Brothers, 241 Dovercourt Road, have commenced the erection of apartments ,estimated to cost $50,000, and have let the contract for excavation to E. Corner, 698 Manning Avenue. Brick and stone construction.

Walkerville, Ont.

. In connection with the residence in course of erection for F. E. Allum, Detroit, Mich., the carpentry has been awarded to the general contractor, plumbing to R. Hicks, 159 Wyandotte Street E., heating to J. E. Purser, 30 Glengarry Avenue, and electrical work to Gilbert Campeau, 121 Tuscarora Street.

Windsor, Ont.

The contract for plumbing required in the erection of a flat for Mrs. T. Hallett, 1 Dougal Avenue, has been let to Fletcher & Jones, Windsor Avenue, and the electrical work to W. Lefave, 235 Bruce Avenue.

Power Plants, Electricity and Telephones

Brooke Township, Ont.

The Township Council intend to petition for the installation of a hydro-electric system. Clerk, W. J. Weed, Inwood, Ont.

Edmonton, Alta.

The Provincial Legislature have ratified the agreement between the Edmonton Power Company, c|o G. W. Farrell & Company, 43 St. Fancois Xavier Street, Montreal, and the City Council for the supply of power for 21 years. The project includes the construction of a large dam, power houses and electric railway. The contract for dam and power house may be let to Sir John Jackson, Ltd., London, England. Approximate cost, $6,000,000.

Enniskillen Township, Ont.

The Township Council propose to secure estimates on the cost of a light and power system. Clerk, G. V. Wyant, Petrolia.

Ingersoll, Ont.

The Town Council are considering the installation of an ornamental lighting system on the paved streets. Clerk, W. R. Smith.

Kingston, Ont.

The City Council are having plans prepared for electric lighting at Barriefield Camp. Clerk, W. W. Sands.

St. Francois de Beauce, Que.

The Beauceville Telephone Company propose to construct a system at an approximate cost of $10,000. Secretary, A. Doyon.

CONTRACTS AWARDED

Amherstburg, Ont.

The Town Council have let the contract for the installation of a street lighting system to the Ontario Hydro Commission, Toronto, and work will be done under supervision of the Commission's Engineers. Approximate cost, $5,000.

Should Engineering Societies Pass On Public Questions?

A short time ago a reinforced-concrete structure was being built in a certain city under the supervision of that city's engineer. Rerolled steel, employed as the reinforcing material, was objected to by one of the city aldermen, who brought the matter to the notice of the council. The city engineer was asked to explain. The argument fast degenerated to the see-saw order, and a deadlock resulted. The papers then took a lively interest in the matter, and last of all that Colossus of astute intelligence—the man-in-the-street—began to furbish up some of the minor parts of his subconscious stratum.

When a deadlock is established in a controversy, one of the contending parties is very apt to undertake hasty action. Otherwise, complete collapse results. In this particular case the council, instead of taking the matter in hand and obtaining a report on the dispute by some competent person, collapsed.

What next happened was to the writer incomprehensible. An engineering society, uninvited, informed the council that it would be pleased to go into the matter, its services to be given free. The old adage, "Beware of entering into a quarrel," etc., had no terrors for the society. It did not occur to the members that they were exposing themselves to a rebuff in case the council awakened to a sense of its responsibility and again took the matter into its own hands.

* * *

This incident brings up the question—Have our engineering societies the right to assume the role of adjudicator on all subjects of an engineering nature? The writer wishes, if possible, to ascertain on what authority some individuals have assumed to pass upon engineering matters and then branded their findings with the name of an engineering society. In looking through the constitutions of engineering societies it is difficult to find any laws or rules that clothe the members with judicial authority. Neither has the writer ever heard of any unwritten law or custom bearing on the subject. From this he concludes that the members of our societies never intended that their names should be used in public investigations such as that just cited.

No matter how high sounding our societies' titles may be, we should never lose sight of the fact that these associations are composed of fallible men. Our societies generally recognize this fact, and for this reason they have not included in their plan of organization any provision for investigations of a public nature. As an illustration of the statement that engineering societies are composed of fallible men, the writer asked one of the executive of the society that proposed the investigation referred to what his views were on the subject. This gentleman said that he did not care two straws whether any reinforcing was used in the structure or not! This statement is analogous to that of a baker who informs you that he can make currant bread without currants.

* * *

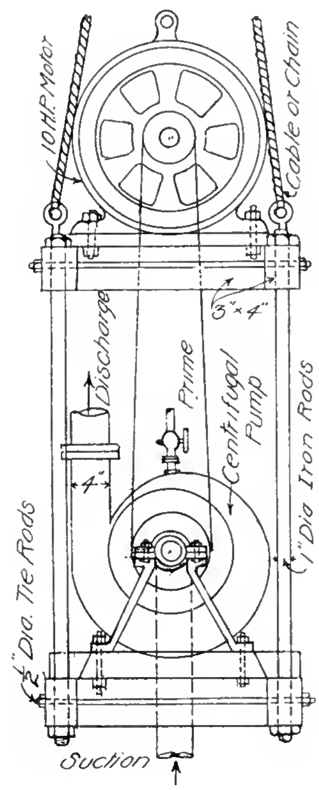
When a society intrudes in such a manner, we naturally ask ourselves,—What is this being done for? It is said that there is never a good action done but that there is a small grain of bad in it. The truth of this saying can be seen on a moment's reflection. Did the society offer its services with the intention of placing its decision in the category of "no higher appeal," or was there some extraneous consideration?

If the intention was to place the finding of the society above the opinion of the individual, then the society is curtailing the freedom of the profession. If the intention was to allay the public's fear concerning the material under discussion and if the finding was given with respect to this, then the interference of the society was most harmful. Such a decision would have an influence not measured by the engineering ability of the investigators at all, but measured solely by the good or bad judgment of the men composing the committee. Nevertheless, the committee's decision, being announced as an action of the society, would have with the public a weight that it otherwise would not have. If engineering societies are going to interfere when and where they think proper, what will be the state of mind of the private practitioner? He will never know when he may be brought to account.

Engineering has long passed the stage of mere algebraic formulas. We are no longer dealing only with the x's and the y's; other elements, often very difficult to estimate, have entered into the calculation. They may take the form of expediency or they may be cost figures or they may come under some other head. These other elements have under present conditions a strong influence on our engineering calculations. They are often the controlling considerations. In other words, they are functions of our engineering problem and will often determine the success or failure of a scheme. Our engineering societies, judging from their constitutions, are not concerned with anything outside engineering science, so the harmonizing of this science with general advancement should be left with the private practitioner. For these reasons the writer believes that our societies should not take upon themselves the role of "courts of appeal."—Hugh J. Duffield, in Engineering News.

Electricity and Construction Work

The utilization of electricity in sewer construction and foundation work has reached an advanced stage in Canada and the United States. In addition to pumping purposes, electric motors are used in connection with travelling cranes, for operating air compressors for use in driving, riveting, steel piling, etc.,



A Typical Example of the many uses to which Electricity can be put.

for electric shovels, for excavating, on gantries used in laying concrete pipe, and other numerous duties. Soil excavated is removed by trucks drawn by electric locomotives, and the necessary materials, tools, etc., are conveyed to the work by the same means; they also provide transportation for workmen.

The reduced cost of hydro-electric power in Canada and the United States has done much to promote the use of electricity for power purposes on construction work. Besides, there can be little doubt that from the point of view of convenience and ease of handling, electricity is superior to the old-fashioned methods even at present employed by some of our contractors.

The accompanying illustration is a typical example of the many uses to which electricity is now put. It shows the adoption of an electric motor in keeping caissons and foundation excavations free from water. The apparatus consists of a 4-in. centrifugal pump, mounted on a heavy steel and wood frame, belt-connected to a 10-h.p. electric motor. The motor is bolted to the top of the frame about 6 feet above the pump to eliminate any danger from water striking the motor and destroying the insulation, thereby injuring the motor. The whole unit is suspended by heavy chains from a crane or derrick or some adjustable means of support above the excavation, and can be placed at any desired depth or position in the trench. This makes it exceedingly effective for this kind of work.

Committe to Supervise

Under a by-law which has received its first reading, the city of Westmount will appoint a committee to supervise the construction of all buildings and all alterations. The committee will be composed of the mayor, the general manager and the engineer of the city, all ex-officio, four architects, and any other persons that the council may appoint from time to time. Each member of the committee will act without any remuneration. Several architects have already offered their services. All plans and specifications will have to be submitted to the committee, and a decision is to be made within seven days. If an alteration is suggested by the committee, a decision may be postponed beyond the period of seven days, but this postponement is subject to the agreement of the applicant. An appeal to the council may be made from the decision of the committee. The by-law does not dispense with the necessity of obtaining the usual permit. Infringement of the by-law renders any person liable to a fine of $40 for the first offence. Four members, two of whom must be architects, form a quorum.

Pan-American Road Congress

The proceedings of the Pan-American Road Congress have just come to hand. The congress was held under the joint auspices of the American Road Builders' Association, the American Highway Association, with the co-operation of the Pacific Highway Association, at Oakland, Cal., September 13, 14, 15, 16 and 17, 1915.

The proceedings, which covered ten sessions—two each day, included all addresses, reports, etc., besides papers and discussions on 27 subjects covering the various factors involved in road and street administration, construction and maintenance, delivered by men prominent in their special branches. The proceedings, which cover 416 pages 6 in. x 9 in., are paper bound and are on sale by the executive committee of the Pan-American Road Conference, 150 Nassau Street, New York, for $2.00.

The Standard Underground Cable Co. of Canada, Limited, announce that their Montreal branch office is now located in the McGill Building instead of the New Birks Building as heretofore.

New Steel-Arch Bridge at St. John, N.B.

To Replace Old Suspension Bridge Over Gorge at the Reversible Falls—Span 565 Feet—Deck 50 Feet Wide

DUE to the increasing density and volume of traffic, the old suspension bridge over the St. John River at the Reversible Falls, St. John, N. B., had become inadequate and the provincial government of New Brunswick, to meet the increasing demand, has built a new long-span steel arch bridge. The new bridge is one of unusual interest, ranking, with its 565 ft. span, among the first half dozen of America's long-span steel bridges. It is a street crossing to take the place of the old suspension bridge which was built in 1852 by William K. Reynolds on the design of Edward Serrell, on almost the same location. The late C. C. Schneider, Philadelphia, recently a member of the Quebec Bridge Commission, was retained as consulting engineer on the new bridge, and with his associate, F. S. Kunz, designed a steel spandrel-braced arch spanning the rock gorge. The width and height of the gorge are such as to make the arch of unusually flat proportions. The span is 565 feet. The ratio of rise to span is 1 to 9.2. In due proportion, the crown depth is small, 8 ft. 6 in., while the depth at the end post (set 2½ ft. forward of the skewback hinge) is 60 ft. 3 in. The top chord and roadway have an initial grade of 3.215 per cent. The arches are set in vertical planes.

The truss spacing is 41 ft., for a 50-ft. deck, comprising 36-ft. roadway and two 7-ft. sidewalks. The curbs are thus set a short distance in from the inner face of the top chord, and the sidewalk bracket outside the top chord is correspondingly shortened. The panel length is 23 ft. 4 in. uniformly (24 panels).

The structure is of thoroughly modern highway-bridge character as regards detail. This means heavy solid floor and large live-load capacity. The floor is a 6-in. reinforced-concrete slab on I-beam stringers, with a surfacing of 4-in. creosoted wood block. The sidewalks are 4½-in. slabs surfaced with ½-in. cement mortar. Two trolley tracks occupy the middle of the roadway. The bridge also carries an 18-in. cast-iron water main.

The dead-loads are summarized by the following tabulation for the completed condition and for erection conditions respectively:

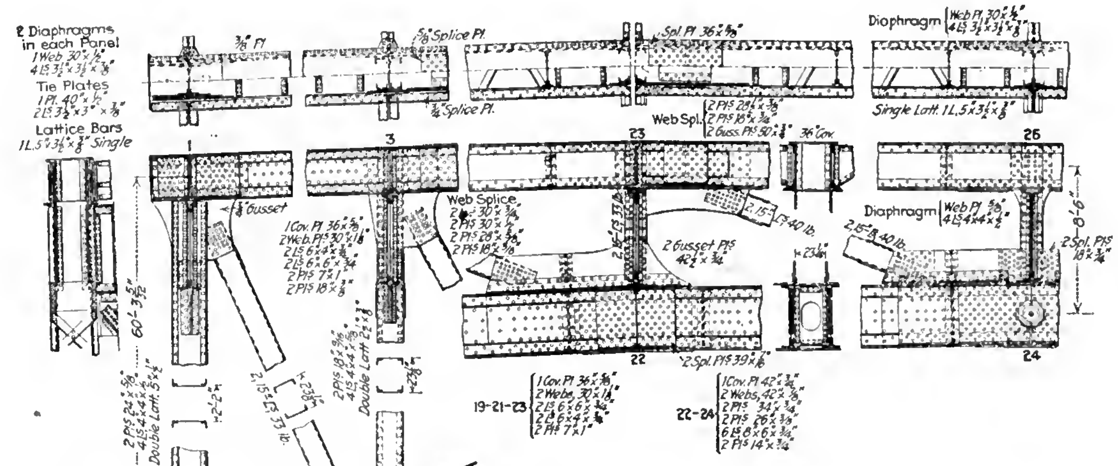
Dead-Load of St. John Arch

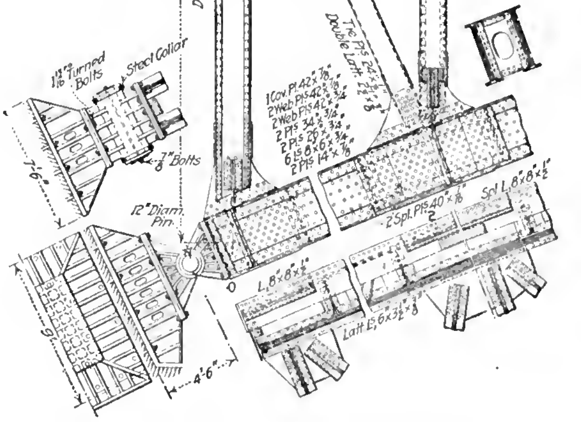
(In lb. per lin. ft. of bridge)

After completion:	
Flooring, rails, water pipe, etc.	5,100
Floor system	1,300
Trusses and bracing, average	5,600
Total, average	12,000
Maximum during erection:	
Stringers, floor-beams and rails	700
Trusses and bracing, average	5,600
Total, average	6,300

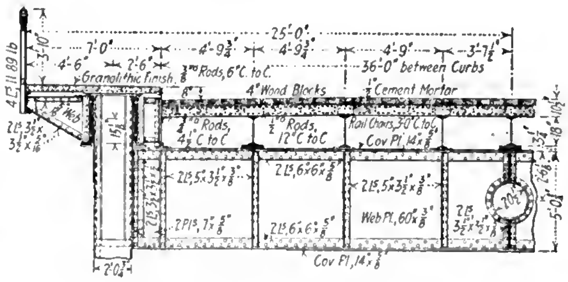
The average loads given were not used in the calculations, but the actual panel concentrations were

Fig. 1—Erection of Steel-arch Bridge in centre, Suspension Bridge to left since Removed.

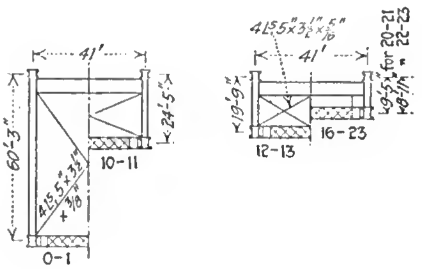




TYPICAL DETAILS OF ARCH



HALF CROSS-SECTION



TYPICAL SECTIONS

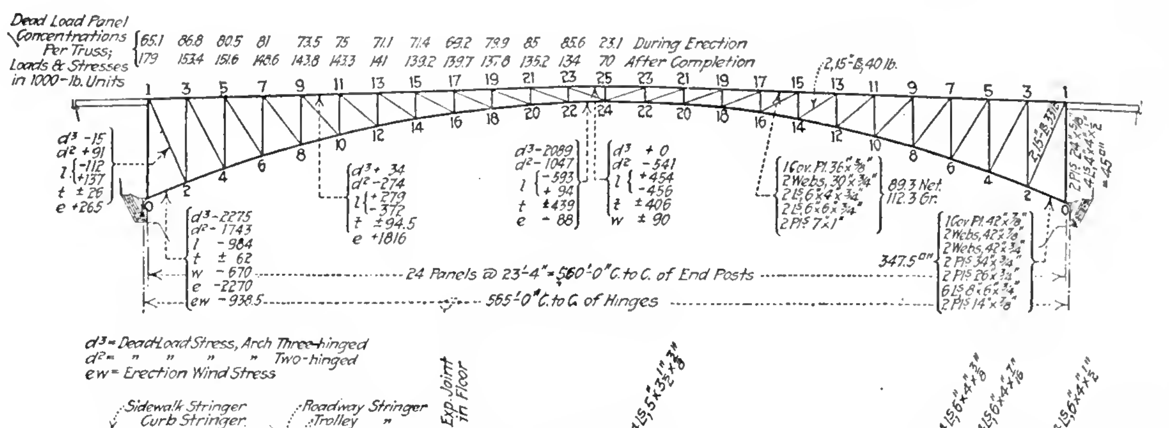
Live-Load Specifications

For roadway stringers, one 20-ton road roller.

For trolley stringers and floor-beams, on each track two 8-wheel 40-ton cars end to end, plus 25% impact.

For sidewalks, 100 lb. per sq.ft.

For main trusses, 3,000 lb. per lin.ft. of bridge. This represents 60 lb. per sq.ft. over the whole area between railings, or else 40-ton 40-ft. trolley cars on each track spaced 40 ft. in the clear on both tracks, and 36 lb. per sq.ft. on all other floor surface.



OUTLINE SKETCH OF REVERSIBLE FALLS ARCH, WITH LOADS AND TYPICAL STRESSES

Fig. 2—Bridge Details of Steel-Arch Bridge at St. John, N. B.

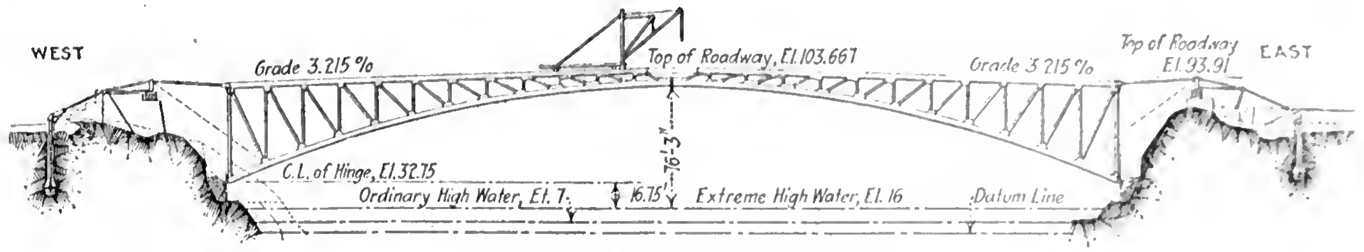


Fig. 3—Erection Sketch of Reversible Falls Steel Arch.

taken. A traveller load of 75 tons was taken into account in computing erection stresses.

The live-load was graded for the design of the different structural parts from stringers to main trusses. The specifications for live-load are given in the bridge details shown.

Method of Erection

The trusses were erected without falsework, by the usual cantilever method. The arrangement of anchorage and adjusting toggles for the erection and closure is shown by the sketch, Fig. 3.

Closure was made by inserting the top chord mem-

Fig 4—View showing the Cantilever Railway Bridge, New Steel Arch and Suspension Bridge at St. John, N. B.

ber without stress, after lowering the half trusses to contact on a pin at the centre bottom-chord joint. The bridge is thus three-hinged for the erection dead-load, but is two-hinged for live-load and temperature.

The main span is flanked by two 46-ft. 8-in. deck plate-girder spans. The total length of steel superstructure is 654 ft. between back walls.

The contract for the work was let early in 1913 by the Chief Commissioner of Public Works, John Morrissy, to the Dominion Bridge Company, Montreal. A. R. Wetmore was Provincial Engineer.

It is of interest to note that the cantilever railway bridge near the arch, which can be seen in the photographs, is, like the suspension bridge, a historic structure. It was erected in 1884, just after Mr. Schneider's Niagara (Michigan Central) cantilever, and thus was among the first three or four of modern cantilevers in America. The Dominion Bridge Company built it. Its main span is 477 feet long, containing a 143-ft. suspended span. The suspension bridge, also shown, has since been removed. We are indebted to the Engineering News for the above information.

Mr. R. T. Stull, Ceramic Engineer of the Dunn Wire-Cut Lug Brick Company of Conneaut, Ohio, was elected an honorary member of the Paving Brick Institute at the recent meeting at Portsmouth, Ohio.

Contracts Secured

The London Concrete Machinery Co., Limited, of London, Ont., advise that they have recently secured contracts to supply the following machinery:—

M. A. Congdon, Digby, N.S., with a half yard batch mixer; George Hintz, Bridgeport, Ont., with one quarter yard mixer; Wm. Rosebush, Frankford, Ont., with one 1/6 yard mixer; Robert Lattimer, Strangefield, Ont., with 1/4 yard batch mixer; Lewis & Midgley, Hamilton, Ont., with one quarter yard mixer; Thos. McCormick, Carman, Min., with 1/6 yard mixer; H. V. Gray Construction Co., Merriton, Ont., with a 3/4 yard batch mixer; Ontario Paper Company, Thorold, Ont., with one half yard batch mixer; Arthur Desautels, Crysler, Ont., with a complete plant for making cement sewer pipe and culvert tile; Wright & Company, Hull, Que., with cement drain tile machine, tile cars, etc., to be installed in their new plant; Henry Rebidoux, Amherstburg, Ont., with 1/4 yard batch mixer, also cement drain tile machine and concrete block machine, to be installed in his new concrete plant.

Australian Steel

A notable industrial triumph, marking a new era in the development of the Commonwealth's resources, has been achieved in the manufacture of steel of the highest quality at the works of the Broken Hill Proprietary Company at Newcastle, New South Wales. The steel has been highly tested by representatives of the Imperial Munitions Department, with such successful results that a first order was given to the Company for 500 tons of steel to be shipped during February, for use in the manufacture of munitions in Great Britain.—United Empire.

Daylight Saving Law

The City Council of St. John, N. B., has enacted a by-law putting the Daylight Saving Law in operation in that city from midnight April 30 until the same hour on September 30. St. John is thus the first city in Maritime Canada to adopt Daylight Saving, as it was the first to adopt the commission form of civic government and the town planning system. The provincial legislature will be asked to pass an Act making the daylight saving movement effective throughout the province.

J-M Asbestos Roof

In our description of the Robert Simpson warehouse, which appeared in the April 26 issue of the Contract Record, it was omitted to note that the roofing to be applied on this building is a J-M built-up Asbestos Roofing, being installed by the manufacturers, the Canadian H. W. Johns-Manville Co., Limited.

Developments in Bituminous Roads

Construction Methods in Laying Bitulithic, Warrenite and Topeka—Specifications—Present Status of Patent Litigation

By Arthur H. Blanchard, M.C.S C.E.*

Before proceeding with the discussion of the many improvements in the construction of bituminous macadam and bituminous concrete pavements which have been developed during the period from 1914 to 1916, it is advisable, in order to avoid misunderstandings, to quote the definitions of the two types of pavements as recommended by the Special Committee on "Materials for Road Construction" of the American Society of Civil Engineers.

"Bituminous Macadam Pavement. One having a wearing course of macadam with the interstices filled by penetration methods with a bituminous binder."

"Bituminous Concrete Pavement. One composed of stone, gravel, sand, shell or slag, or combinations thereof, and bituminous materials incorporated together by mixing methods."

Certain developments which are common to both classes of bituminous pavements will be discussed prior to considering improvements which specifically refer to each of the several types.

Foundations

There has been a general acknowledgment of the ultimate economy of constructing adequate foundations to support the amount and character of traffic which the several types of bituminous pavements are able to carry. In the case of bituminous macadam pavements, this development usually has been characterized by the construction of well compacted and, in many cases, thoroughly filled broken stone foundations. In the case of bituminous concrete pavements, due to numerous failures which have occurred where this type of pavement has been built on old macadam or poorly constructed broken stone foundations, there has been a general tendency to advocate the use of cement-concrete foundations from four to six inches in thickness. It has generally been found that the cost of cement-concrete foundations does not exceed the cost of well compacted and filled broken stone of equivalent strength. Furthermore the use of cement-concrete foundations renders repairs and renewals more satisfactory and much easier of accomplishment.

Non-Bituminous Highway Materials

There has been a general recognition since 1914 of the desirability of covering in specifications in more detail and with greater rigidity the physical properties of the aggregates to be employed and the sizes of the particles which compose such aggregates. For example, the 1914 Specifications of the American Society of Municipal Improvements covering bituminous macadam pavements state, with reference to the physical properties of the stone, that the rock employed must meet the following requirements:

"The broken stone shall be subjected to abrasion tests and toughness tests conducted by the Engineer in accordance with methods adopted by the American Society for Testing Materials, August 15, 1908. The broken stone used for the construction of the first and second courses shall show a French coefficient of wear of not less than 7.0 and its toughness shall be not less than 6.0. The broken stone used for the construction of the third course and for the first and second applications of No. 1 broken stone shall show a French coefficient of wear of not less than 11.0 and its toughness shall not be less than 13.0."

The necessity for more carefully drawn specifications covering the sizes of the particles of which a given product of a stone crushing and screening plant is composed is illustrated by the following mechanical analyses of two products obtained from the same plant, both of which products passed over a section of a rotary screen having circular holes of 1¼ inches and through a section of a rotary screen having circular holes 2¼ inches in diameter.

	Sample "A" Per cent.	Sample "B" Per cent.
Passing ⅛ inch screen	0.2	0.1
Passing ¼ inch screen	0.1	0.1
Passing ½ inch screen	0.4	1.1
Passing ¾ inch screen	2.2	12.6
Passing 1 inch screen	8.0	37.5
Passing 1¼ inch screen	29.1	40.9
Passing 1½ inch screen	27.1	7.7
Passing 2 inch screen	32.9	0.0
	100.0	100.0

It is hence obvious that for many forms of bituminous construction, in order to secure successful results, greater care must be used in the writing of specifications for products of broken stone. As an illustration of an improvement in specifications covering this detail, there is cited those adopted at the 1915 Convention of the American Society of Municipal Improvements covering broken stone to be used for the aggregate of one type of bituminous concrete pavement.

"Broken stone for the mineral aggregate of the wearing course shall consist of one product of a stone crushing and screening plant. It shall conform to the following mechanical analysis, using laboratory screens having circular openings: All of the broken stone shall pass a one and one-quarter (1¼) inch screen; not more than ten (10) per cent. nor less than one (1) per cent. shall be retained upon a one (1) inch screen; not more than ten (10) per cent. nor less than three (3) per cent. shall pass a one-quarter (¼) inch screen."

It is noted that in this form of specification an attempt is made to cover in the mechanical analysis only the limits of the smallest and largest particles. No attempt is made to secure a carefully graded aggregate but simply a product suitable for the type of pavement in question and uniform in character. For example, the following mechanical analyses show three products used in the successful construction of three different bituminous concrete pavements of the type mentioned.

	Sample "A" Per Cent.	Sample "B" Per Cent.	Sample "C" Per Cent.
Passing 1/8 inch screen	1.2	2.7	1.0
Passing ¼ inch screen	4.2	5.6	2.5
Passing ½ inch screen	34.7	45.0	30.8
Passing ¾ inch screen	40.6	35.1	34.2
Passing 1 inch screen	17.3	10.1	23.4
Passing 1¼ inch screen	2.0	1.5	8.1
	100.0	100.0	100.0

There has recently been considerable discussion pertaining to the advisability of the adoption of so-

* Before the Canadian and International Good Roads Congress, Montreal.

called "alternate type" specifications in preference to the so-called "blanket" specifications for bituminous materials. By alternate type specifications is meant a series of specifications, each of which covers the physical and chemical properties of the most desirable grade of a given type of bituminous cement for the purposes for which it is to be used. On the other hand a blanket specification covers in one set of requirements, pertaining to physical and chemical properties, all the types of bituminous cement which are to be used in connection with the construction of a given kind of pavement. For example, in the case of specifications for asphalt cement for bituminous concrete pavements, it would be desirable under alternate type specifications to have not less than five sets of physical and chemical requirements, the limits for each requirement being as narrow as the several processes of manufacture would permit, while on the other hand a blanket specification would cover with a wider range of limits the same chemical and physical properties for the five types mentioned. As an illustration will be cited the limits in the case of Specifications "A" to "E" inclusive under the alternate type specification method for specific gravity, and the penetration at 25 degrees C. (77 degrees F.)

Alternate Type Specifications

	A		B		C		D		E	
Sp. Gr. ..	0.97	1.00	1.00	1.03	1.03	1.04	1.025	1.05	1.04	1.06
Pent.	75	90	90	100	70	90	85	95	140	160

In the case of a blanket specification to cover the same grades of the several types, the limits for specific gravity would have to be 0.97 to 1.06 and the limits for penetration would be 70 to 160. The penetration test, for example, can only be of maximum value when applied to the grade of a specific type of bituminous cement which is most suitable for the type of pavement in question. In the case of the bituminous concrete pavement of the type mentioned, the proper penetration limits for a California asphalt lie between 70 and 90 while for a fluxed Bermudez asphalt to be used in exactly the same type of pavement and under the same conditions, the penetration limits should be between 140 and 160. It is evident that to attempt to cover the penetration limits for both materials in one specification is impracticable. In the first place such limits as 70 to 160 are so wide as to insure but little uniformity in different lots of the same material and in the second place an entirely unsuitable material of one class could be supplied under the maximum or minimum test limits of the other class.

The proper use of alternate type specifications allows the contractor to bid to supply so many tons of bitumen which will comply with any one of the sets of requirements. It will be noted, therefore, that the contractor is in exactly the same position as in the case when he bids to supply any asphalt cement which will comply with the requirements of a blanket specification.

Guarantees

There has been a general tendency to abandon the use of guarantees on bituminous pavements as it is believed that, with proper specifications and efficient supervision and inspection, guarantees are not necessary and that the requirement of a guarantee materially increases the prices bid on a given pavement. The subject of guarantees is too broad to discuss in this paper.

Bituminous Macadam Pavements

In addition to the improvements noted above, the most notable recent development in the construction of bituminous macadam pavements has been in connection with the compaction of the road metal and the distribution of the bituminous materials.

As a result of the numerous failures of bituminous macadam pavements which have occurred due to the improper rolling of wearing courses of road metal prior to the application of bituminous material, there has been a general recognition of the necessity for more thorough compaction of the road metal. This principle has been recognized by the Special Committee on "Materials for Road Construction" of the American Society of Civil Engineers in its 1915 Report, the conclusion referred to reading as follows:

"An important factor for successful results is the proper compaction by rolling of the road metal before the spreading of the bituminous material."

The above Committee emphasizes another improvement which is aimed at the use, in some cases, of an excess amount of bituminous cement in this type of pavement. This conclusion is as follows:

"Present indications are to the effect that the use of bituminous materials in quantities of more than 2½ gallons per square yard where the upper course of the macadam is to be 3 inches in thickness after compaction is inadvisable under the penetration method."

There has been a general recognition of the advisability of using properly designed distributors in connection with the application of bituminous materials in order to secure uniform distribution economically. Some specifications cover the requirements which a distributor must meet. For example, the 1914 Specifications of the American Society of Municipal Improvements contain the following paragraph pertaining to the pressure distributor.

"The pressure distributor employed shall be so designed and operated as to distribute the bituminous materials specified uniformly under a pressure of not less than twenty (20) pounds nor more than seventy-five (75) pounds per square inch in the amount and between the limits of temperature specified. It shall be supplied with an accurate stationary thermometer in the tank containing the bituminous material and with an accurate pressure gauge so located as to be easily observed by the Engineer while walking beside the distributor. It shall be so operated that, at the termination of each run, the bituminous material will be at once shut off. It shall be so designed that the normal width of application shall be not less than six (6) feet and so that it will be possible on either side of the machine to apply widths of not more than two (2) feet. The distributor shall be provided with wheels having tires each of which shall not be less than eighteen (18) inches in width, the allowed maximum pressure per square inch of tire being dependent upon the following relationship between the aforesaid pressure and the diameter of the wheel: For a two (2) foot diameter wheel, two hundred and fifty (250) pounds shall be the maximum pressure per linear inch of width of tire per wheel, an additional pressure of twenty (20) pounds per inch being allowed for each additional three (3) inches in diameter."

This specification provides for a distributor by which it is practicable, under competent supervision, to secure uniform application of the bituminous material and allows the use of a pressure distributor without danger of rutting of the wearing course of broken stone by narrow tires carrying excessive weights.

Bituminous Concrete Pavements

The improvements in the construction of bituminous concrete pavements to which attention should be called will be considered under the following classification of the three types into which bituminous concrete pavements generally may be divided. These types are designated as follows:

(a) A bituminous concrete pavement having a mineral aggregate composed of one product of a crushing and screening plant.

(b) A bituminous concrete pavement having a mineral aggregate composed of a certain number of parts by weight of volume of one product of a crushing and screening plant and a certain number of parts by weight or volume of fine mineral matter such as sand or stone screenings.

(c) A bituminous concrete pavement having a predetermined mechanically graded aggregate of broken stone or gravel, either alone or combined with fine mineral matter, such as sand or broken stone screenings.

Patents

Unfortunately the present status of patent litigation has to be considered in connection with the discussion of the several types of bituminous concrete pavements. The majority of engineers and highway officials are interested in the types of bituminous concrete pavements which may be constructed without danger of litigation rather than in a prolonged discussion of the probabilities of successfully defending suits for infringement. There is ample evidence at hand that bituminous concrete pavements of type (a) may be constructed without danger of litigation proceedings provided that the mineral aggregate is of the general character heretofore mentioned in this paper under the section "General, Non-Bituminous Highway Materials."

The history of litigation cases indicates that the construction of bituminous concrete pavements of type (b) on a large scale will in all probability lead to litigation. The same remarks apply to the construction of bituminous concrete pavements of type (c) except in the case of the so-called Topeka bituminous concrete pavement with an aggregate of the type specified either in the 1910 Topeka decree, or of the grading which was adopted at the 1915 Convention of the American Society of Municipal Improvements.

Materials

Type (a). Practice has demonstrated that broken stone, because of the satisfactory mechanical bond secured, makes the most suitable aggregate for this class of bituminous concrete although pavements constructed with gravel have proved satisfactory for light traffic where great care has been taken in the selection of the gravel and in the construction of the pavement. The development of the character of materials used in current practice has been covered in this paper under the title "General." Much more care has been taken in recent years with reference to the quantity of bituminous cement to be used in the mix. There has been a general recognition that the amount used depends upon the kind of road metal and the bituminous material, the character of the aggregate and the climatic conditions. For the product of broken stone heretofore mentioned, it has been found that bituminous concrete mixtures should contain between 5 and 8 per cent. by weight of bitumen.

Mixing

Many improvements are noted in the methods employed in the mixing of bituminous concretes. There has been a general evolution from hand mixing methods to the utilization of mechanical mixers especially designed for the manufacture of this type of bituminous concrete.

There has been considerable discussion pertaining to the proper type and weight of roller to be used for the compaction of the wearing course. Experience demonstrates that in order to secure an even surface and adequate compaction by thorough interlocking of the particles of broken stone, a tandem roller weighing between 10 and 12 tons should be used.

Seal Coat

Many methods have been developed for the application of the seal coat of bituminous material. It has been found that seal coats of from ½ to 1 gallon per square yard of bituminous cement are distributed most uniformly by the use of hand-drawn gravity distributors followed by a squeegee.

Experience in many localities has demonstrated that bituminous concrete of this type should not be mixed or laid when the air temperature in the shade is below 50 degrees F. as otherwise it is difficult, under average conditions, to secure an even and well compacted wearing course.

Type (b). Specifications for this type of pavement have, during recent years, generally stipulated that so many parts of broken stone and so many parts of sand or other fine material are to be mixed with a certain amount of bituminous cement. By the use of this specification, unless employed under unusual supervision, it has been found to be impracticable to secure a well graded aggregate. In many cases the mixture has contained an excess of broken stone with insufficient fine material to fill the voids therein, while in other cases it has contained an excess of sand in which the broken stone exists as isolated particles. It is the conclusion of many engineers, because of the conditions described, that when bituminous concrete pavements are to be employed either type (a) or type (c) should be selected.

Type (c). During recent years, the bituminous concrete pavements of this type which have been most extensively employed are known as Bitulithic, Warrenite, and Topeka.

Bitulithic and Warrenite. Differentiation.

The general use of Bitulithic and Warrenite bituminous concrete pavements throughout America has brought up for discussion the matter of the fundamental differences between these two types of patented pavements. It is believed that it will be of interest and value to the engineering profession to submit the following statement, prepared by Mr. George C. Warren, President of the Warren Brothers Company, for the information of the engineers enrolled in the Graduate Course in Highway Engineering at Columbia University.

"Bitulithic and Warrenite mixtures are both made under the provisions of the Warren patents, which the courts have held 'cover the product no matter how produced.' Bitulithic is designed to meet the conditions generally prevailing on city streets, and Warrenite is to meet such conditions as may arise on country roads so as to meet the physical and economic conditions and public demands as to cost.

"Generally speaking, Bitulithic is mixed by a plant which is too cumbersome to meet country road conditions, which provides for combining the materials proportioned by separation of sizes of the aggregate, after heating, and then recombining by weight.

"Warrenite is, generally speaking, mixed by a plant so portable that it may be set up either alongside the railroad; along the side of the road being constructed, or in the quarry or gravel bank from which the bulk of the aggregate is being procured as may be most economical in any particular case. This plant is constructed on the principle of proportioning the several separated sizes by careful measurement by bulk before heating and retaining the batch so measured as a separate entity through the process of heating and delivery into the mixer in which the bituminous cement is added.

"Generally speaking, crushed stone predominates in the fine aggregate of Bitulithic, while sand predominates in the fine aggregate of Warrenite; also, fine crushed stone and sand respectively are correspondingly used for the seal coat aggregate.

"In the selection of quality of material (whether gravel or crushed stone) for the coarse aggregate a greater latitude is permitted in the case of Warrenite to practically meet the conditions of less opportunity for selections which are liable to prevail in localities considerable distance from railroad centres. This latitude is allowed, because while the traffic conditions on country road thoroughfares are in point of weight and concentration of traffic rapidly becoming fully as severe as on most city streets, there is the important difference that on country roads generally the traffic is more exclusively the motor vehicle rubber tire type and consequently less exaction in physical properties of the quality of the stone forming the basis of the aggregate is necessary. Also, unfortunately, many city streets are abused by constant excessive sprinkling or daily scoured by pressure flushing machines, a practice which is more or less injurious to any road surface, while country roads are seldom, if ever, wet except by rainfall; therefore, in cases where the very best quality of stone is unavailable, it would be safe to use stone of slightly lower quality in Warrenite on a country road although the same quality stone might not be safe for use in Bitulithic on a city street."

Topeka

In many specifications the mineral aggregate for the Topeka pavement specified has been that contained in the decree of 1910, namely,

"Bitumen, from 7 per cent. to 11 per cent.

Mineral aggregate, passing 200-mesh screen, from 5 per cent to 11 per cent.

Mineral aggregate, passing 40-mesh screen, from 18 per cent to 30 per cent.

Mineral aggregate, passing 10-mesh screen, from 25 per cent to 55 per cent.

Mineral aggregate, passing 4-mesh screen, from 8 per cent to 22 per cent.

Mineral aggregate, passing 2-mesh screen, less than 10 per cent.

Many unsatisfactory pavements have resulted by the unintelligent use of this grading. It has been found necessary, in order to secure successful results, to specifically define the character of the sand or other fine material which shall be employed in order to secure a satisfactory grading. Many specifications now cover the sand grading with almost the same care as in the case of sand grading requirements for sheet asphalt pavements. In order to encourage the use of a more satisfactory grading for this type of pavement, the American Society of Municipal Improvements in 1915 recommended the adoption of the following grading:

Passing 200-mesh screen	7-10 per cent.
Passing 80-mesh screen, but retained on a 200,	10-20 per cent.
Passing 40-mesh screen, but retained on an 80,	10-25 per cent.
Passing 20-mesh screen, but retained on a 40,	10-25 per cent.
Passing 8-mesh screen, but retained on a 20,	10-20 per cent.
Passing 4-mesh screen, but retained on an 8,	15-20 per cent.
Passing 2-mesh screen, but retained on a 4,	5-10 per cent.

Fourth Annual Report of the Public Utilities Commission of Manitoba

The fourth annual report of the Manitoba Public Utilities Commission for the year ending November 30, 1915, has just been published. The report terminates the period of office of the present commissioner, Mr. H. A. Robson.

The appointment of Mr. George Guy as electrical engineer of the Commission is announced, which, it is expected, will greatly facilitate the work of the Commission, as Mr. Guy's professional ability and practical experience will be invaluable in settling the many technical matters which are constantly arising. The Commission have removed their offices from Somerset Building to more capacious accommodation in 201 Tribune Building.

Professor Albert F. Ganz, appointed by the Commission to discover and apply a remedy to prevent injury to water pipes by stray electric currents from electrical railway return circuits, presented his report, and upon it the Commission, issued an order against the Winnipeg Electric Railway Company to install and establish a proper system of bonding and cross-bonding of the rails in order to provide a continuous conductor and prevent stray currents. The Winnipeg Electric Railway Company have resisted this order, and have entered an appeal in the Court of Appeals for Manitoba against it.

The enlargement of the Commission by the appointment of an electrical engineer will open a field of assistance to municipalities about to enter into public utility undertakings. The Commission will thus be enabled to investigate and advise on municipal contracts in the public interest, and thereby assist in securing proper construction and operation methods such as will ensure efficient service. Municipalities and public utility companies will be free to ask the Commission for advice as to the feasibility of any proposed public service, and the Commission may investigate and recommend what service will be in the best interests of the municipality. This will undoubtedly prove a valuable aid to municipal and privately owned utilities throughout the province and be the means of bringing all concerned into closer relationship.

Utilizing Domestic Coal

In the report presented at the last session of the Legislature on the possible hydro-electric development in the province, reference was made to lignite coal and its possible adaptability for power purposes. The government gave practical demonstration of its interest in the investigations and experiments made by the Commission through its gas engineer, Hugh McNair, upon the uses of native coals for power production throughout the province. The installation of a model gas producer plant, which the government has authorized to be purchased in England, will demonstrate the possibilities of using the lignite coals of this province and Saskatchewan economically for power and heating purposes. If the experiment should prove the practicability of this, a great step forward will have been accomplished in supplying a readily adaptable form of power, and at the same time converting into an asset part of the large bodies of lignite coal and peat lying dormant here. The plant will be installed at Souris, where experiments already have been conducted by the Commission's gas engineer.

Telephone Report

The financial statement of the Telephone Commission of Manitoba for the year ending November 30, 1915, appears in this report. The service given to subscribers has on the whole been satisfactory.

Depreciation Account

The Public Utilities Act of Manitoba provides that the Commission shall have power after hearing upon notice, to require every public utility to carry, whenever in the judgment of the Commissioner it may be reasonably required, a proper and adequate depreciation account for the protection of stock holders, bond holders or creditors. Soon after the Act came into effect the depreciation reserve fund of the Manitoba Government telephone system was established, according to the rates of depreciation fixed. As the fund is made up of percentages of assets which may not wear out or require replacement, it accumulates. As there appeared no likelihood for its immediate need, it was considered advisable to invest a portion in bonds of the province.

The general report states briefly the number and nature of enquiries and investigations held by the Commission during the year, and recounts briefly all the matters of varied character which came before the Commission's attention.

Program for Montreal's Annual Municipal Clean-up Campaign

Montreal has had a clean up campaign since 1912, when the Mayor made an official proclamation of a clean up day at the instigation of the City Improvement League backed up by a petition signed by 132 public bodies and institutions. In that year and the following year operations were confined to one day, but the movement was so successful that in 1914 and 1915 the period was extended to a week, and this year—May 14-20—the same time is allotted to the efforts to put the city in a cleaner state. Owing to climatic conditions, Montreal is in a much more unfavorable position than many United States cities; the lanes are choked with ice and snow during several months, and although the garbage is removed regularly, a certain amount of decaying matter and ashes is bound to accumulate and is covered by successive layers of snow, making it imperative to have a clean up week in the spring.

While in the United States the initiative is taken by the insurance companies, in Monteal it is in the hands of the City Improvement League and the Montreal Publicity association, assisted by the civic departments. The funds for the propaganda and other expenses are raised by contributions, with a civic grant. The work done is practically all voluntary, and is carried out by a number of committees, to which are relegated various sections of the activities of the campaign. The chairmen of these committees are responsible for the carrying out of the particular work, entailing a large amount of personal attention and organizing effort. Owing to the mixed character of the population, all literature has to be printed in French and English, and in this connection it may be noted that the two nationalities co-operate in a very cordial way.

In 1912 in addition to a clean up day, a great Child Welfare or Health Exhibition was held for two weeks, to which the public were admitted free of charge, while two years later the general movement received a decided impetus from the fact that the Montreal Publicity Association joined hands with the League, a week's campaign being then decided on, at the suggestion of Mr. F. Abraham, president of the former body. The city provided a certain amount of money, and the heads of the incinerator, fire and health departments joined the general committee. The clergy of all sects and races have undertaken the first day of the week as "Sermon Day." This year the School Commissioners of the city have promised their special co-operation, through the medium of the teachers and the schools.

The nature of the campaign can be judged from the following programme:

Sermon Day

Sunday, May 14th—Hear the sound advice from the pulpits to keep physically and morally clean.

Fire Prevention Day

Monday, May 15th—Bear in mind that carelessness is the chief cause of fires—and that each fire prevented means thousands of dollars saved to the community.

Front Yard Day

Tuesday, May 16th—Make the surroundings of your home congenial—sow grass on the lawns, plant flowers—take good care of the trees.

Back Yard Day

Wednesday, May 17th—Clean your backyard of all rubbish—make it a small vegetable garden. Keep the fences in order. Whitewash them with lime.

Sanitation Day

Thursday, May 18th—Remove all rubbish, clean all carpets, ventilate your cellars. Scrub everything. Use plenty of soap and water everywhere.

Paint Up Day

Friday, May 19th—Make everything radiant with fresh colors. Follow the example set by nature. Be bright. Keep bright.

Children's Day

Saturday, May 20th—50 per cent. of the newly born babies die before they are one year of age. Do something to stop these needless deaths. It is worse than murder to keep infants unclean—and to give them food that is worse than poison. The clean-up campaign two years ago saved the lives of 200 infants. Last year it saved 382 lives more than the preceding year. It may save yours this year.

The feature of the 1915 campaign was the enlisting of children's interest in the work—due to the suggestion of Dr. W. H. Atherton, who had been the organizing secretary of the Child Welfare Exhibition in 1912. It was felt that no better way of securing sanitary conditions could be devised than to obtain the co-operation of the boys and girls. This year, greater emphasis and concentration is being laid on this department and with the co-operation of the schools the programme is arranged with this end in view. In order to encourage the children, $1,250 are being given in prizes. The city is divided into five districts, $250 being allotted to each. The children are reached mainly through the various schools. The teachers ask the pupils who desire to enter the competition to sign a form, which provides for two competitions, one from May 7 to June 7, and the second from then to end in September. The second competition is an optional supplementary one, with other prizes, obtained through the Merchants' Committee, for those who will keep up the good work until the end of the summer. The points to be considered by the District Organization Committee in judging are as follows:

Relative to Backyard—The absence of all rubbish, such as cans, ashes, broken glass, straw, chips, etc. Also freedom from weeds.

Relative to Front yard—Absence of all rubbish, cans, straw, etc. Freedom from weeds. Front yard in grass, and if kept trimmed.

Relative to Exterior Improvement.—The painting of the exterior of the house, such as verandahs, balconies, etc. Or if these do not need painting this year, the cleaning of them. The cleaning out of sheds. The painting or whitewashing of sheds. The strengthening of fences, and the painting or whitewashing of same. Or the screening of them with vines or flowers.

Relative to. Flower and Vegetable Planting—The making of flower gardens, in the front yard, and the putting of flower boxes in the windows. The making of vegetable and flower gardens in the back yard. Several beds of vegetables, such as radishes, beets, carrots, etc., can be made in the centre of the yard, with some flowers around the sides, along the fences. The care given to flowers and vegetables after planting.

Relative to General Improvement—Consideration given to state of premises before work of cleaning-up, and planting begins.

Relative to General Appearance of Premises.—The judges to give consideration as to how all parts of the premises have been given attention. The contestant to win must have a well balanced piece of work.

The scoring to count as follows: general appearance of back and front yards relative to cleanliness to score up to 30 per cent.; general exterior appearance to score up to 20 per cent.; flower and vegetable planting to score up to 25 per cent.; general improvements to score up to 15 per cent.; general appearance to score up to 10 per cent.

Another feature this year is to be moving pictures at several halls in the different districts. This is an extension of work previously done in the same direction. In other years at the spring cleaning lantern slides of an educational and hygienic character were shown, though in 1914 moving pictures were exhibited in the parks later in the summer. In order to vary the interest, moving pictures of a general character will be shown together with those of educational value, and in this manner the minds of the children will be impressed in a way which is calculated to have a permanent effect. The children are also, at the various meetings, asked to sign the following pledge:

"I want to help make our town a better place to live in, and to this end I promise to comply with the following rules to the best of my ability:

1. I will help clean up yards, streets and alleys.

2. I will plant flower seeds, bulbs, vines, shrubbery, etc.

3. I will help make gardens, and keep lawn in good condition.

4. I promise not to deface fences or buildings, neither will I scatter paper or rubbish in public places.

5. I will not spit upon the floor of any building or on the sidewalk.

6. I will try to influence others to help keep our town clean.

7. I will always protect birds and animals, and all property belonging to others.

8. I promise to be a true, loyal citizen.

I may not be able to do all these things, but will do as much as I can to help our town and community.

Sign and Mail this to P. O. Box 368, Montreal, or hand same to your school teacher.

Prior to clean up week circulars were sent to all the large industrial plants, stores, etc., asking that an individual clean up campaign be made of the premises. This had been acted upon with willing co-operation, and the employees are thus set an example which will likely be followed around their own homes.

The City Improvement Campaign Committee takes every means to impress on the public the importance of following out the programme. Through the daily press and the Publicity Committee attention is drawn to the various items, while the committee in charge of the particular day also makes inspections. In addition thousands of booklets are distributed; these insist upon the absolute need of sanitation, as the means of preventing disease and death. The clean up week has also become a Public Health week. In this year's pamphlet, Dr. Boucher, the chief of the health department, suggests rules for saving children, and enumerates five "Don'ts" as to methods of sanitation. Fire Chief Tremblay also tells how to prevent fire.

The work of the City Improvement League is by no means confined to the clean up campaign, as it is interested in town planning, the care of public parks and trees, the extension of vacant lot gardens, and good government generally.

Preservation of Woodwork

Generally speaking, any wood will last a long time when protected from moisture. It would, however, lose its agreeable color and surface unless some means are used to protect it. The use of chemical preservations is confined almost entirely to underground timbers and so has little use in millwork. One of the places millwork would be benefitted by chemical treatment is at the base of porch columns, where treated wood might well be used where water is apt to penetrate. Creosote is the best of practically all preservatives, and there are a number of methods of using it. Paint is also effective if water can be kept out of all cracks, crevices, joints, etc. Where the paint merely holds the water in a pocket, we have the ideal conditions for fungus growth and ultimate decay.

A Few Suggestions for the Solution of the Single-House Sewage Disposal Problem

The growing popularity of modern conveniences in the shape of water and sewage conveniences in isolated and rural residences or in small communities, has resulted in the establishment of a more or less standard arrangement very much improved as compared with the practices of a few years ago. For the solution of the single-house sewage disposal plant there may be used the plain sedimentation tanks, such as leaching cess-pools and sewage cisterns; septic tanks of different forms and the double deck or Emscher tanks. The first type is rarely used being as a rule not very satisfactory; leaching cess-pools are a serious menace to wells in the vicinity due to possible soakage through the soil and contamination of the water; little or no reliance can be placed on the surface slope of the ground with respect to placing a cess-pool relatively to the well; the under strata may slope directly opposite to the surface and form a very effective drain from the cess-pool into the well. Sewage cisterns are usually unsatisfactory because they involve the periodical removal of sludge, a troublesome problem.

Septic tanks have increased in favor with the public and sanitary engineers since their introduction as a means of sewage treatment and are very widely used though often incorrectly and more or less unintelligently. The two storey or Emscher tank is coming to be favored by sanitary engineers, because it produces a fresh, well settled, effluent, and provides for a very complete retention and thorough digestion of the sludge. This type is adapted for a small community rather than for single houses.

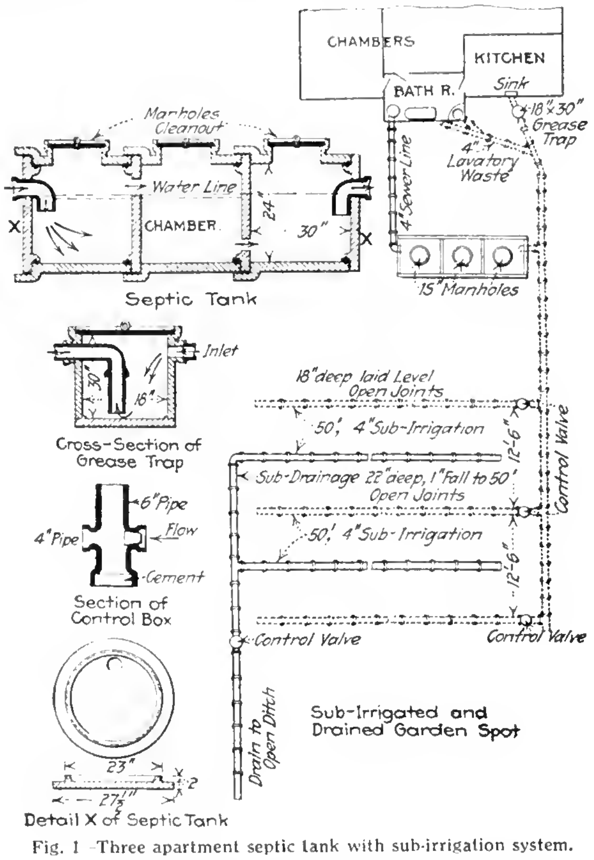

Fig. 1 -Three apartment septic tank with sub-irrigation system.

For a small community the only adequate solution of the sewage disposal problem is a well planned system of sewers covering the entire community. The entire system need not be built at once, but only as deemed necessary and as the community is able to finance it. The whole system should, however, be planned in advance before any mains are laid at all. Treatment of sewage by carrying it to a single outfall by intercepting sewers is, relatively to the size of the community, very expensive and not always satisfactory—depending largely on the grade and slope or the topography of the town site.

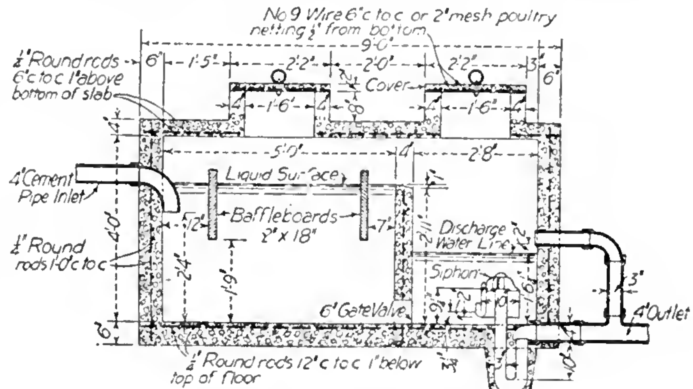

Fig. 2—Single apartment septic tank with siphon and siphon chamber

The system of sewers which, with very few exceptions, is best adapted to meeting the necessity of a small community for purifying the sewage is the so-called separate system, as distinguished from the combined system, and is more economical with a reasonably good natural drain.

In a community with a stream into which the sewers may empty, if the flow exceeds 5 cubic ft. per second for 1,000 persons, crude sewage may be discharged directly into it without nuisance, if the outfall is properly designed to insure a good mixture of sewage with the water in the stream. If the minimum stream flow is below 5 cubic ft. per second and over 3 cubic ft. per second for 1,000 persons using the sewers, then some form of fine screening or treatment in tanks to remove solids is necessary. As fine screening cannot be applied except on a rather large scale, the small community is practically confined to the use of tanks. If the dilution available is less than 3 cubic ft. per second for 1,000 population, some form of filtration must be added, such as sand filters, contact beds or sprinkling filters.

Leaching cess-pools and sewage cisterns are usually nothing more than some form of containing receptacles built to suit requirements. The septic tank in its simplest form is a single apartment bottomless tank or a tank set on timber, built in loose sandy soil in which the effluent will soak away. The bacteria which compose the mat on the surface of the sewage liquor and feed on the raw sewage, converting it into clear effluent, are anaerobic requiring no air to carry on the chemical decomposition of the raw sewage.

The next step in the development of the septic tank is that used in heavier soils which requires distributing tiles to dispose of the effluent. The layout of such a tank is shown in Fig. 1. It is a vitrified-clay septic tank with sub-irrigation tiles distributed beneath the owner's garden. The tank is in three sections or chambers of 2 ft. x 2½ ft. each, with an estimated daily capacity of 50 gallons.

The kitchen and bathroom waste need not pass through the septic tank, but may go directly to the sub-irrigation system. Only sewage containing solids or putrescible matter need pass through the tank.

A still further modification of this style of tank is one employing a syphon chamber and a syphon, as shown in Figs. 2 and 3. This tank shows only one section but it may be enlarged to any number to suit the capacity of the system. The use of the syphon regulates the discharge so that a relatively large

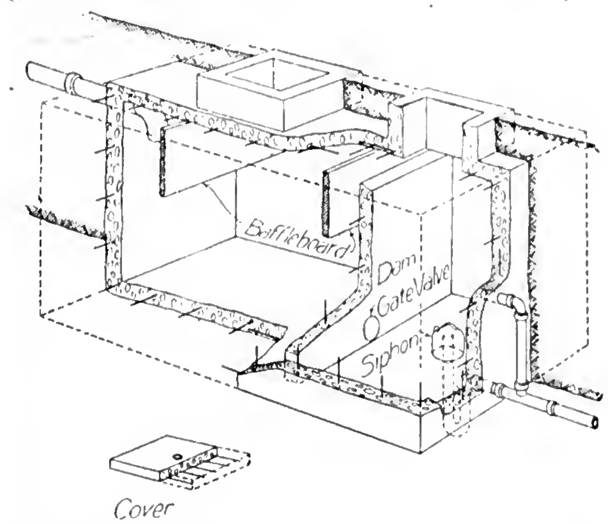

Fig. 3—Perspective of tank shown in Fig. 2, showing concrete construction.

amount of effluent is discharged into the tile, in a short space of time providing a pressure head which distributes the effluent to the extreme end of the tile lines. If no syphon is employed and the tile slope is comparatively small, the discharge is slow and the ground near the tank is likely to become over-saturated and sour.

Where a sewer outlet or a tile disposal system for the effluent is used, the tank should be built of reinforced concrete entirely, as shown in Fig. 3. For average capacity, a 4 in. inlet and outlet is sufficient, although it is better to have pipes too large rather

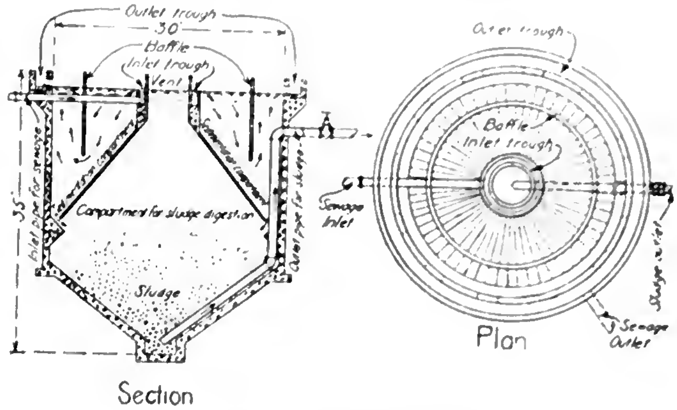

Fig. 4—Double Deck or Emscher Tank.

than too small. Place the tile in porous ground, if possible avoiding tight soil, at a distance of at least 24 in. underground. With pipes at this depth very little trouble from frost will be experienced; keep the top of the tank at least 8 in. to 10 in. below ground level to avoid danger from frost. This depth need not be excessive, as a certain amount of heat is generated by the chemical action of the decomposition of the sewage.

Fig. 4 shows an Emscher sewage tank. Sewage is introduced in the centre and passes under a battle plate which causes the sediment to pass down through the sediment department into a sludge digestion chamber, from which, when thoroughly digested, it is pumped off. Sanitary engineers claim for this tank very good results, producing a well settled effluent and a thoroughly digested sludge.

New Station for the L. E. & N. at Brantford, Ont.

In connection with the Lake Erie and Northern electric railway, now in course of construction from Galt to Port Dover, it is proposed to erect a large station at Brantford. The new line, which will connect with the C. P. R. main line at Galt, is open from the latter town to Brantford, and it is hoped to have the entire line to Port Dover completed by June. In addition to the usual passenger service, arrangements are being made to carry considerable quantities of freight.

The station at Brantford is to be one storey in height, and will be located over the tracks at the south west corner of Colburn and Water streets, with a 38 ft. frontage on Colburn street and 70 ft. on Water street. The tracks will pass beneath the main floor of the building, with platforms, express and baggage accommodation at the lower level. New England, Colonial style, red brick and limestone trimmings are to be used for the exterior, the roof being of green slate. The main floor at the street level, with an entrance from Colburn street, will contain a waiting room 35 feet x 50 feet, a women's retiring room, and lavatory, men's lavatory, and ticket and telegraph offices. The seats extend the full length of the two outside walls in the waiting room, except in the space occupied by the ticket and telegraph office. Two

New L. E. & N. Station at Brantford, Ont.

stairways will lead from the main floor to the track platform. Provision is made for the express room and the steam heating apparatus in a separate extension 14 ft. wide x 75 ft. long, on the lower or track level. This extension abuts on the retaining wall of Water street and will be accessible for teams at the lower end of the street. The interior of the building will be finished in Canadian Ash, while the walls and ceilings of the main waiting room are to be plastered and finished with plastered cornices. The floors are of concrete. The toilet rooms will have marble wainscots 6 ft. x 9 in. high. The estimated cost is $25,000.

The Canadian Northern Pacific Railway Terminals at Victoria, B. C.

When General Manager MacLeod, of the Canadian Northern Pacific Railway, visited Vancouver on March 28th he carried with him the plans of the company's $1,000,000 terminal passenger depot and of its freight terminals to be erected on the reclaimed lands in False Creek, Vancouver. Mr. MacLeod was accompanied by Mr. R. B. Pratt, architect of the company, under whose supervision the plans were drawn. At a conference with the bridges and railways committees of the city council—which body has been anxiously awaiting a start on construction—Mr. MacLeod stated that as soon as the plans were approved by City Engineer Fellowes he was ready to call for tenders for the foundation and main structure, and would promise that no time would be lost in its erection. After hearing the representatives of the company explain some of the details, the plans were referred to the city engineer to ascertain if the structure as shown on paper would conform with the company's agreement with the city as to cost, namely, $1,000,000.

The drawings presented show a structure of classical Doric design, 321 feet long by 120 feet wide, of modern fireproof construction. Twelve huge Corinthian columns stand at intervals across the entire front. The centre portion of the proposed structure reaches to a height of 100 feet from the ground, the tower proper being 96 feet high. The ends of the building stand 64 feet high, and those portions between the centre and the ends, 60 feet high. These sections are three storeys in height, while the ends and the centre portion are four storeys high. The building is designed for white or grey stone.

Many modern features are embodied in the interior design. A large main entrance is provided in the central portion through which a passage runs into a very wide lobby leading into the general waiting room, 150 feet long and 50 feet wide. In this room are the ticket offices, etc. Adjacent to the ticket offices is the baggage room and on the opposite side of the building, with means of access from the waiting rooms, are the lunch and dining rooms. There are numerous lobbies off the waiting room. A barber shop is provided; a men's waiting room and a women's waiting room and retiring room; a government mail room and the dining and sleeping car department; C. N. Express company and commercial telegraphs. The upper storeys are devoted to traffic offices, and the basement is to be utilized for storage purposes, etc.

A great passage-way leads from the waiting room to the train tracks at the back of the station. Here a large covered concourse is provided, 50 feet wide and covered platforms from 1,200 to 1,500 feet long. Provision is made for sixteen tracks.

The floors throughout are of terrazzi and marble; the stairways are marble and the finish throughout is in natural wood. It will take from nine months to one year to erect and complete the depot.

B. C. Material to be Used

Mr. MacLeod stated that it was his company's intention to purchase as much of the material required in British Columbia, as is possible, and Mr. MacLeod was told the city would want stone instead of terra cotta wherever the latter was called for.

The ground plans show the location of the depot sixty feet south of the proposed Great Northern station. A main roadway, 125 feet wide, running east from Main street, divides the company's property in

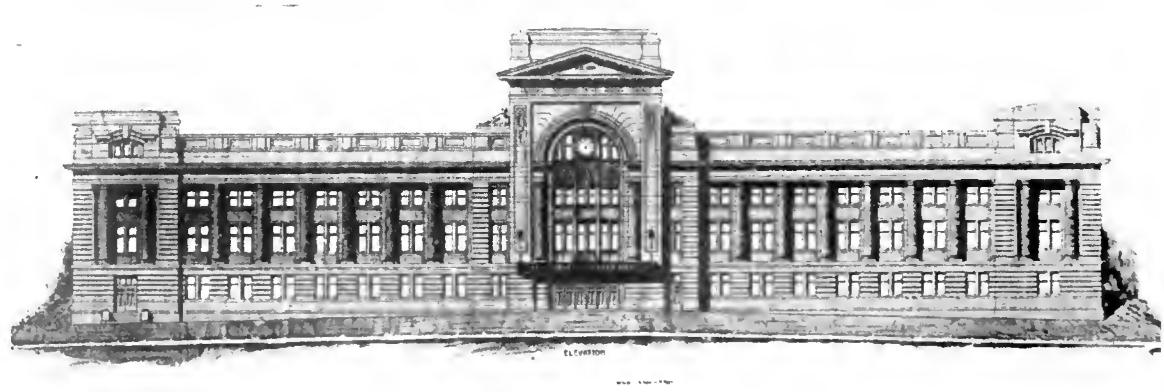

Fig 1—Architect's perspective of the C. N. P. Terminal, Victoria, B. C.

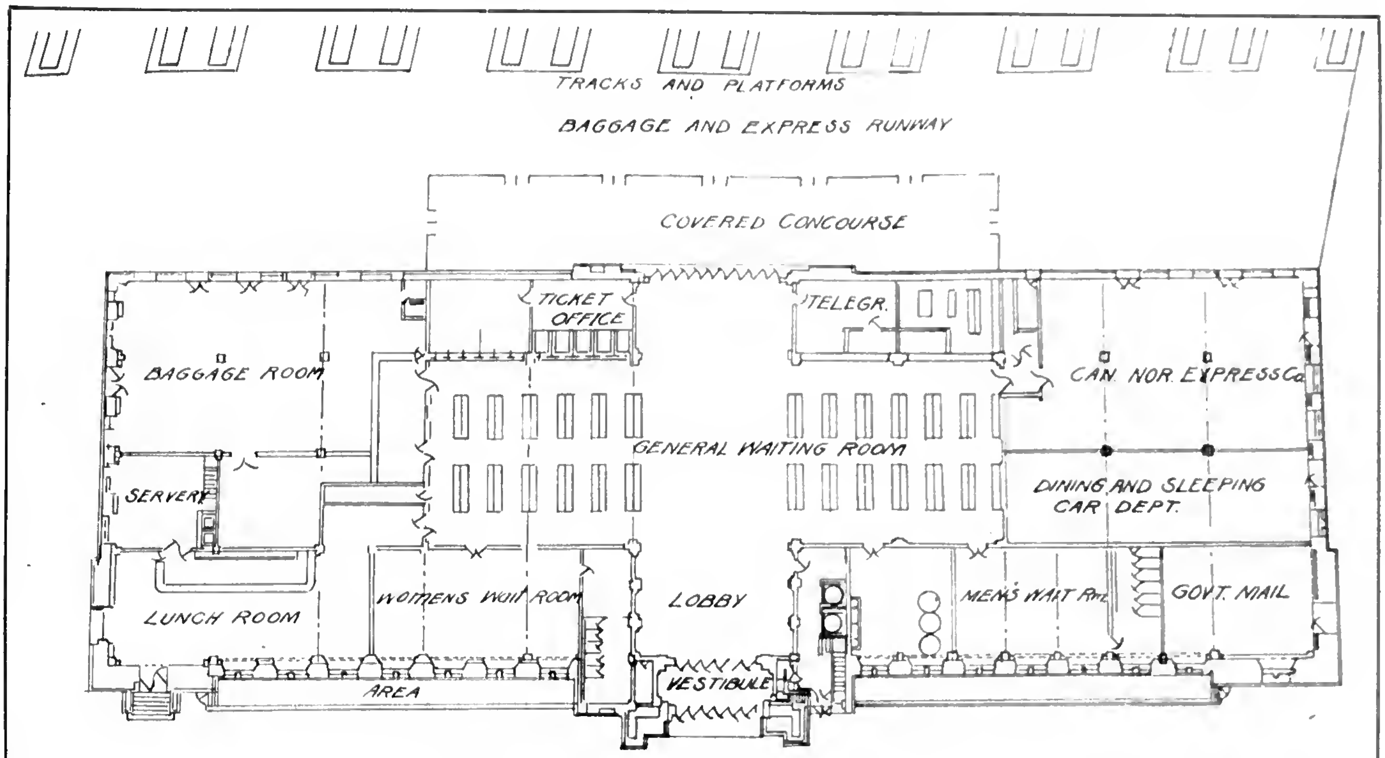

Fig. 2—General Layout of the C.N.P. Terminals at Victoria, B. C.

two, on either side of which provision is made for industrial sites on the north and freight sheds on the south. According to the agreement with the city, 12 acres at the northeastern end of False Creek are left. This belongs to the city. A roadway, 125 feet wide, is shown in front of the depot, running from north to south.

American Lead Pencil Co., New York

A unique and useful sample box is being sent on request to technical and professional men by the American Lead Pencil Co. of New York, who have had made up at considerable expense a box about three inches square, which contains nine degrees of Venus pencils, ranging from hardest to softest, also a pencil holder and a small size of the new Venus eraser. This little test kit enables the recipient to determine exactly which degree of hardness or softness best suits his purpose, so that in the future he can order a certain degree and know that it is exactly what he requires.

London Concrete Machine Company, Limited

The London Concrete Machinery Company, Limited, advise us that they have been awarded the following contracts:—Mr. Camillus Van Caeseele, Langenburg, Sask., to be supplied with 1/6 yard batch mixer; Shawinigan Water and Power Company, Shawinigan Falls, Que., with a 1/3 yard batch mixer; Mr. Ernest Jones, Granton, Ont., with a ¼ yard batch mixer; Mr. W. H. Casselman, Chesterville, Ont., with a 1/6 yard batch mixer.

The B. F. Sturtevant Company, Boston, Mass., are distributing general catalogue No. 195, which describes, with illustrations, the various Sturtevant products.

Mr. Lucius E. Allen, Consulting and Constructing Engineer, Belleville, Ont., announces the removal of his offices to the New Bank of Commerce Building.

Miscellaneous

Mr. J. H. Kilmer has been appointed city engineer and inspector of water-works construction at Port Moody, B. C.

Active preparations for the "Good Roads Day" in Pennsylvania counties, which has been set for May 25, are being prosecuted by the counties of the state.

The Dominion Stove and Foundry Company, of Penetanguishene, Ont., are enlarging their plant in preparation for installing machinery for the manufacture of furnaces.

The new Wychwood branch library, Toronto, the gift of the Andrew Carnegie Library Trust, was formally opened on April 15, in the presence of a large number of residents of the neighborhood.

The demand for building and repair permits in Quebec during the week ending March 11 was quite brisk, there being issued eleven permits, representing an amount in new buildings and repairs of $14,590.

Because the owners would not consent to an early closing agreement, the plumbers and gasfitters of Hamilton, Ont., have been called out of the shops of Drake-Avery Company, Adam Clark, W. J. Walsh, and A. Rogers & Company.

The death is reported of Ex-Ald. John Martin, a former building contractor of Hamilton, Ont., at the age of 73. Eighteen years ago Mr. Martin left Hamilton to settle on a fruit farm at Vinemount, where he resided till the time of his death.

There continues to be a good deal of discussion in Ottawa relative to the proposal to increase the maximum height of buildings from 110 to 130 feet. Mr. Frank Darling, of Toronto, the architect for the Federal Town Planning Commission, who has been asked by the Board of Control for his opinion on this subject, is strongly in favor of the present limit of 110 feet being unaltered. He argues that as Montreal, a purely commercial city, finds that 130 feet answers all requirements, the capital of the Dominion should be willing to concede something in order that the Government buildings may largely dominate the city. The Board will take no further action in the matter until they get an idea of the Government's view.

City of Kamloops Hydro-Electric Plant

Detailed Description of Engineering and Economic Features of Power Generating and Pumping Systems of this Growing Western Centre

By H. K. Dutcher, M. Can. Soc. C. E.

It is the purpose of this paper to refer to some of the engineering and economic features in connection with the design and construction of the Municipal power plant and pumping systems of the city of Kamloops, which have been recently completed and placed in service.

These systems include a steam turbine power plant and pumping system, a new reservoir and a hydro-electric power plant and sub-station.

The steam power plant and pumping system, together with the sub-station of the hydro-electric plant are included in the one building, and located near the eastern limits of the city, while the generating station of the hydro-electric plant is located on the Barriere River, which flows into the North Thompson, the distance of this plant from Kamloops being about forty miles almost due north.

During the course of examination of the several streams available for power within practical range of the city, there appeared to be some prospect that a company holding the power rights on the Adams River might develop power from this source, in which case the lands along the South Thompson River would be looked after.

Attention was directed, therefore, mainly to an examination of the streams flowing into the North Thompson River, and of these the Barriere River appeared to answer the requirements for power development most satisfactorily, especially in view of the two large lakes available for storage, the heavy grade of the stream and the convenience of the transmission line passing down the valley of the North Thompson through comparatively open country with a prospect of a power market along the entire route.

After some study of these different factors affecting the immediate and future requirements, the city finally decided to proceed upon the following scheme of construction:—

(a) The development of a hydro-electric power plant on the Barriere River with a capacity of at least 5,000 h.p., of which the first installation would provide for 2,000 h.p.

(b) The construction of a new steam plant and pumping station in the city, the steam plant to provide for either oil or coal fuel, and to have the first installation up to 2,000 h.p. capacity. The pumping plant to include two motor-driven centrifugal pumps to deliver 1,200 Imperial gallons per minute each, and one steam turbine pump of equal capacity.

(c) The construction of a covered concrete reservoir of 1,500,000 gallon capacity but designed for an extension to 3,000,000 gallons by the construction of a second section.

Barriere Hydro-Electric Power System

Barriere River

The Barriere River rises in the mountains near Adams Lake, flows in a westerly direction for a course of about thirty-two miles and empties into the North Thompson River at a point about forty miles north of Kamloops.

The total drainage area of the Barriere River is about 230 square miles, with an average precipitation of probably about 35 inches. The mean flow during a normal year would be about 550 cubic feet per second with extremes of about 3,600 cubic feet per second as a maximum in the early summer period, and 220 cubic feet per second in the low water season of the winter months.

Of the total flow about 80 per cent. comes from the

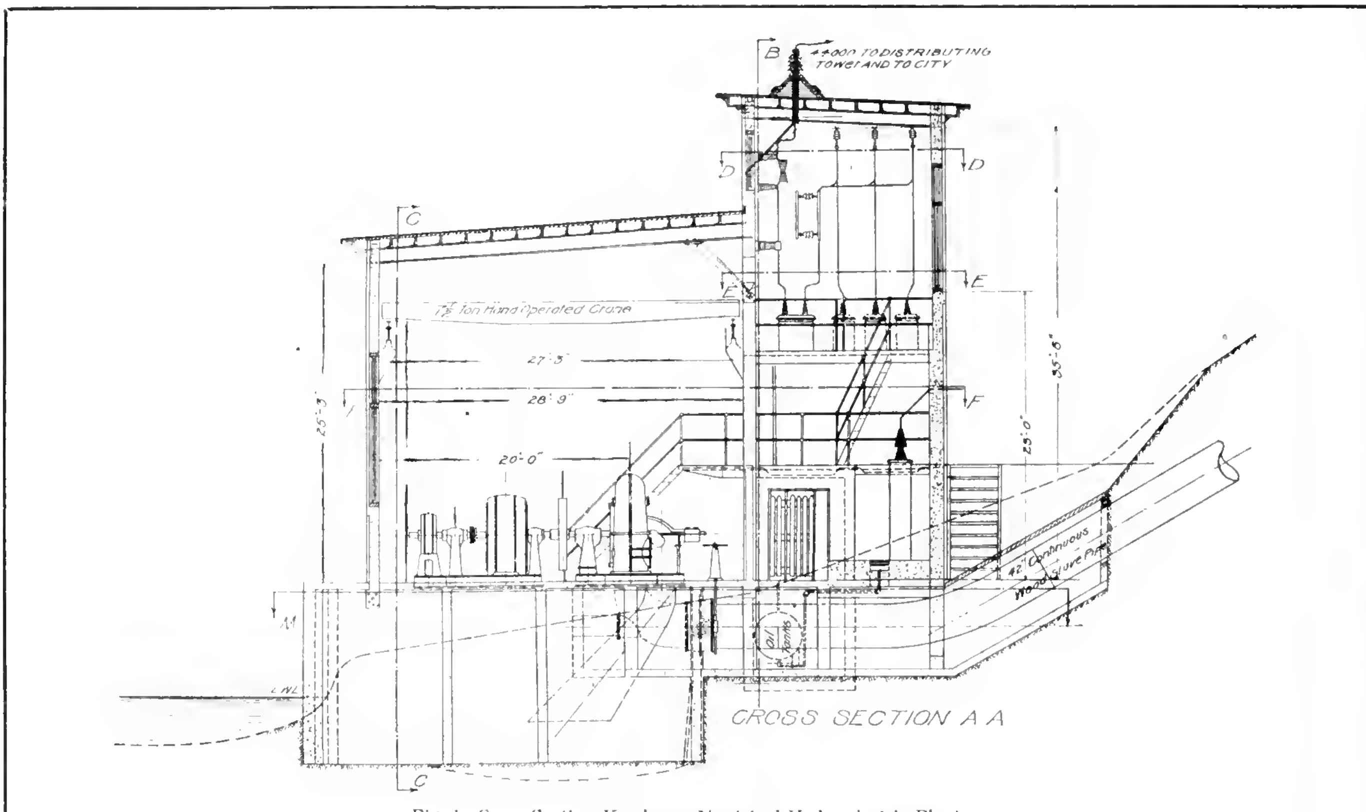

Fig. 1—Cross Section Kamloops Municipal Hydro-electric Plant.

North Barriere Lake, and with the provision of storage for 30,000 acre feet in the East Lake, there should be no difficulty in maintaining a flow of from 300 to 350 cubic feet per second for power development.

Power Development

As the elevation of the North Lake is about 2,100 feet above sea level and the elevation at the outlet of the river is about 1,500 feet, there is therefore an average grade of about 50 feet per mile. The plan of power development provided

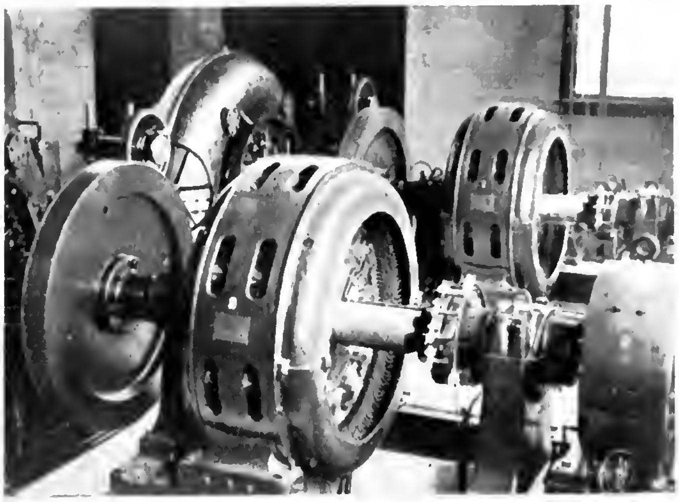

Fig. 2—Interior Kamloops Hydro Generating Station.

for the location of a generating plant at a point about five miles up from the mouth of the river.

For a distance of about 3½ miles above the site of the generating station the grade of the river averages 65 feet per mile, and a suitable site for an intake dam was located to give an effective head of 192 feet at the generating station by 17,800 feet of flume system.

The location of the generating station of the Barriere hydro-electric plant was made, however, with the view to the abandonment of the present intake when the demand for power exceeds the economical maximum capacity of the combined Barriere and steam plant systems as developed, and the development of from 15,000 h.p. to 20,000 h.p. by constructing about ten miles of conduit system direct from the North Lake to the generating station to obtain an effective head of 600 feet.

Flume System

The construction of the flume system, including the intake dam, forebay, and wasteways, was started in February, 1912, the work having been let in one contract, to William Greenlees, of Vancouver.

It was planned to have the entire hydro-electric plant completed, if possible, by the end of the year, and it was therefore important to complete the construction of the intake before the high water flow of the river in May or June.

Intake.—The intake dam is a standard rock fill crib type set with a pile foundation to ensure greater stability. The site chosen enabled a suitable intake to be obtained by raising the level of the water ten feet from the normal level of the stream to the crest of the spillway, the grade of the river above this point being such that the flood level extended about 1,600 feet up stream.

The intake for the flume is located on the north side, and a logway and a fishway are placed on the other side of the spillway, the logway being 12 feet wide and the fishway built in accordance with the requirements of the Provincial Government.

The beds of the stream at the site chosen consisted of a top layer of boulders, underlaid with alternate layers of quicksand and blue clay, but a satisfactory degree of water-tightness was secured by carrying the toe sheeting down to a depth of 12 feet, with the filling of mastic and puddled clay, an earth fill being made over this and carried to a height near the spillway by an easy slope.

The foot of the spillway was carried well down stream on piling, to take care of logs and roots which might get past the boom above the dam. The work was completed without difficulty by the middle of April, and passed satisfactorily the severe test of the high water flow of the following months.

Flume

The flume is designed for an ultimate capacity of 320 cubic feet per second and is 3.4 miles in length from the intake to the forebay. In design it is the standard type of timber flume, 8 ft. wide by 5½ ft. high, built up of 2 x 10 in. fir lumber, supported every four feet, and resting on trestle or cedar sills.

The quality of the lumber available was good, but a better quality of coast fir was used for battens and flooring at those sections where water-tightness was especially desirable. Probably the only section which required special attention in this respect was a length of about 1,000 feet, two miles from the intake, where the flume was carried past a steep bank at a horseshoe bend of the river. There appeared some danger of a slide occurring at this section, either from undercutting of the banks of the river or from water running down from the melting snow or leakage of the flume.

It was desirable, however, to continue the flume, if possible, along this section, in view of the necessity of getting timber down from the mill for the construction of the system, and to avoid the heavier expense of carrying a syphon across the river, the cost per foot of the syphon being about four times the cost of the flume for an equal capacity.

The flume system, including wasteways and forebay for penstocks, was completed in the fall, and unfortunately the city was then obliged to shut down on all work on the hydro-electric plant on account of the failure to sell the balance of the hydro-electric bonds due to the financial stringency.

The system as completed was tested out, however, and found to be in satisfactory condition for service, but when the completion of the plant was carried out, two years later, it was found necessary to build the syphon at the section above referred to, on account of a slide occurring which

Fig. 3—Intake Dam, Hydro Plant, Kamloops, B. C.

carried away about six hundred feet of the flume. This syphon is built with capacity for half the ultimate capacity of the system. It is wood stave pipe construction, 66 inches in diameter, 2,100 feet long and designed for varying head to a maximum of 120 feet.

The advisability of covering the flume as a protection against snow was considered, but as the design provided for a velocity varying from 6½ to 7½ feet per second, and careful inspection was required during the first winters' operation, it was decided to leave the system open until the need of a cover could be better determined from actual experience.

Forebay

The forebay is of timber construction and located in a small depression, so that a hogsback lies between the forebay and the power house as a protection against accident to the water system. Its general dimensions are 18 ft. by 36 ft. long and 12 ft. deep, with ample provision for overflow to a wasteway down a small ravine to the river.

Penstocks

There are two 42-inch penstocks from the forebay to the power house, each 490 feet in length. They were built by the Vancouver Wood Pipe and Tank Company and are of wood stave pipe construction with staves 2½ inches thick and steel bands of ½ in. to ¾ in. diameter, spaced for pressure head from 30 ft. to 210 ft. Each penstock was connected up with its turbine by 28 feet of steel riveted pipe, anchored in concrete and connection between the wood stave and steel pipes was made by an expansion joint.

Generating Station Building

As already noted, the location of the generating station was governed not only by the plans for the present development, which can be brought up to at least 5,000 h.p., but the prospect of a future development of from 15,000 h.p. to 20,000 h.p. by a conduit system direct from the North Barriere Lake was also considered.

At the site chosen, the sub-surface conditions of alternate layers of gravel, quicksand and blue clay, required that the entire foundations of the building should rest on piles, and these were driven to an average depth of about 30 feet to secure a firm support.

The entire structure was built of reinforced concrete, the details for the tailrace and supporting walls, and beams for the units requiring considerable form work. The sand and gravel for the concrete was obtained close by the plant, and there were no unusual features of construction worthy of special mention.

The accompanying plan and elevation of the building show the general arrangement and some details of construction. The building as completed is intended to form half of the final structure, the construction of the other half will be carried out when other units are required.

The present dimensions are 45 feet by 48 feet, making the structure, when extended, 45 ft. by 96 ft. It will be noted on referring to the plans that the arrangement for the installation of the equipment is fairly compact, although the high tension equipment is well separated from the other section. The construction of the generating station was carried out by Wm. Greenlees, of Vancouver.

Sub-Station, Steam Plant and Pumping System

The power line from the Barriere plant is brought across the South Thompson to the steam plant building, located near the river at the eastern limits of the city. The main building is of reinforced concrete construction and is about 90 x 75 feet in ground area. It is divided into three bays, consisting of boiler room, turbine room and high tension sub-station. In the basement at the extreme west end is located a reservoir from which the waterworks pumps take their suction. This basement also contains the condenser and condenser auxiliary. The basement under the turbine room is on the same level as the boiler room floor and the well for the pumps is connected by some six hundred feet of 16 in. mains to the pump house at the river's bank.

The architectural features of the building have been carefully thought out in order to furnish a substantial structure with ample lighting and good ventilation. The roofing over the boiler room is supported by trusses, while that over the turbine room and switchboard is supported by deep web I-beams. The horn gap structure for the high tension lines allows them to come in through the roof cones, well within the confines of the plant.

The reservoir into which the water is pumped is located in the Beckman addition, about a mile away from the plant. There are large mains leading to it with frequent laterals for supplying the various sections of the town. When water is being drawn from the laterals, the head under which these pumps operate is somewhat modified, but it is usually kept within from 320 to 340 feet, depending upon the quantity of water being taken out of the system.

The discharge from the waterworks pumps is measured by a Simplex Venturi meter, located just outside of the building wall, the recording and integrating apparatus being placed in the corner of the turbine room.

Auxiliary Pump House

The auxiliary pump house, located out on the river, contains two vertical centrifugal pumps operated and driven by vertical motors, which are above the highest possible known water level. This pump house is constructed of concrete, and so arranged as to admit water to the inside of the house through long intake pipes connecting the house with a screened inlet located in the middle of the river. The inlet pipes terminate in gate valves hand operated from the motor floor level. These pipes discharge into a separate chamber in which a secondary double system of screens are installed which prevent to a large measure foreign matter getting

Fig. 4—Flume System, Hydro Plant—Kamloops, B. C.

Fig. 5—66" Wood Stave Pipe Syphon, Kamloops Power Plant.

into the system. Beyond these screens there has been constructed provision for stop logs which will serve as an auxiliary means of permitting access to the pumps for cleansing or repairs, should anything prevent the use of the main gate valves for the purpose of shutting off the water.

The pump house is of concrete, heavily reinforced throughout. The water comes through grizzlies or screens into the base of the pump house, and is there handled by the vertical centrifugal pumps. These discharge the water through the 16-in. main above mentioned.

The pumping system is so arranged that the filter beds can be later constructed in the space between the auxiliary pump house and the main pump house. These filter beds are to be of the gravity type and of such elevation as to allow the discharge from the auxiliary pump house to run through the filter beds and then by gravity to the reservoir in the basement of the pump house.

The pumps at the auxiliary pump house are operated from the main switchboard, one of them being operated by standard hand operated starter and the other by an automatic patent starting device controlled by a float switch. This device maintains the water in the reservoir forming the suction chamber for the main pumps at a given level. It is found that by proper regulation of the inlet valves this automatic pump is kept in practically uniform service though its arrangement will permit of its starting and stopping to automatic control at the level in the reservoir.

Engine Room Crane

In order to provide means for readily handling all parts of the power plant machinery a ten-ton hand operated travelling crane has been provided which runs over the entire turbine and pump room. By this means any of the machinery can be readily transmitted for the purpose of inspection or repairs. By means of transfer cars the transformers can be wheeled out under the crane to facilitate handling their cores for inspection or repair should occasion demand.

Contracts

The construction of the main building and pump house was carried out by Messrs. Johnson & Gill, of Kamloops, and the installation of the complete plant equipment was carried out by Messrs. C. C. Moore & Company, of Seattle, and included turbines, units, motors for pumps, and complete switchboard equipment supplied by the Canadian General Electric Company.

Reservoir

The new reservoir has a capacity for 1,500,000 Imperial gallons and is located south of the eastern part of the city, between Eighth and Ninth Avenues at an elevation of 30 ft. head above the river. The 14-in. steel main running up Ninth Avenue connects westward with the old power station through the city distributing system, and eastward through a 14-in. and 16-in. main with the new power and pumping station. This main is lapwelded with Matheson joints and in addition to the regular coating has an extra wrapping of burlap as a protection against the strong alkaline action of the soil peculiar to the district.

The design decided upon was a totally enclosed reinforced concrete type with interior dimensions 160 x 96 feet, and a depth of water of 15 ft. 6 in. at the eastern end. The roof consisted of a four-inch slab resting on a beam work supported on square columns 16 ft. centres each way. The floor has a slope eastward of one foot in its length, and as the columns were all the same length the roof had a similar grade.

The first layer is 4½ in. and was poured before any forms were erected, and had embedded in it No. 26 mesh. After the forms had been removed the final layer 4 ins. thick of selected materials was put on without any particular bond with the first floor beyond carefully washing it down. No mesh was laid on the final layer and ⅜ x ¼ in. "V" joints were left about ten feet from the walls after each day's work. This floor and the wetted area of all walls, which were purposely left rough, was given a plastered coat of 1:1½ well trowelled in, on which was put a glazed finish of neat cement and water. The "V" joints were then poured with hot asphalt. Expansion joints divide the walls vertically into sections about 32 feet long. These were formed by allowing no special bond between sections, apart from a dovetail and a 16-in. gauge copper strip with a ½ in. "V" notch across the joint.

All reinforcement was lapped at least thirty diameters to form the splice. Concrete 1:2½:5 mix was used in the rough floor and all footings, and 1:2:4 mix elsewhere, excepting the plaster coat of 1:1½.

On September 24th, 1911, the reservoir was put into permanent commission. The wisdom of putting in the expansion joints was apparent as cracks soon appeared in the walls, which were in every case isolated at those joints and rendered harmless by the copper strip and subsequent plaster coat. An examination six weeks later showed no traces whatever of leakage, all drains being perfectly dry.

Economics of the Power Plants Systems

On the completion of the above projects the total expenditure was found to be about $550,000, of which $295,000 would be chargeable to the hydro-electric plant, $130,000 to the steam plant and $135,000 to the waterworks system, including the pumping plant and reservoir.

Hydro-Electric Plant

An additional expenditure of $25,000 was made on the hydro-electric plant for the construction of the syphon on the flume system, and the overhauling of the flume after the two years' delay in completing the plant, and all or part of this should be charged to annual maintenance. This charge added to the capital cost would bring the expenditure of the hydro-electric plant to $320,000, or $160 per h.p. installed.

Engineering

The engineering of the several projects included in the systems described and which were intended to form a complete scheme for future development was carried out under the direction of the writer as Consulting Engineer, and his firm, Messrs. Ducane Dutcher & Fergusson, ably assisted by members of the staff, including Messrs. N. M. Hall, W. E. McLean, and H. A. Daubner.

Trade Publications

Asphalt Plant—descriptive catalogue issued by the Warren Brothers Company, Boston, Mass., manufacturers of all kinds of asphalt paving plants, machinery and tools, illustrating and describing their equipment.

Cement Belts—Bulletin 102, issued by the Cement Gun Company, Inc., 30 Church Street, New York, entitled "Cement Gun on the Elephant-Butte Dam, New Mexico," being a reprint from an article in the Engineering News of September 30, 1915, by E. H. Baldwin. The same company have issued bulletin No. 91—another reprint from the Engineering News, entitled "Tunnel Waterproofing with Cement Clay Mortar."

Trade Inquiries

214. **Builders' supplies**—A Cape Town firm, with representatives covering all centres in the Union, asks for quotations on asbestos cement sheets, plumbers' supplies, closet seats, brass taps, three-ply board and school-boards, black and green surface.

227. **Metal ceilings.**—A Newfoundland firm desires to form connection with Canadian manufacturers of metal ceilings for dwelling houses and stores.

Personal

Mr. Charles L. Marble has been appointed secretary and manager of the Wayne Oil Tank and Pump Company, of Woodstock, succeeding F. R. Haven.

Lieut. Eric G. Kingwell, late city engineer, Kamloops, B. C., is making a recruiting tour through the Boundary and Kootenay districts to stir up interest in the Pioneer battalion.

Mr. A. Blair Ripley, who has had charge of the C. P. R. grade separation work at Toronto, has been appointed to command a construction battalion with the rank of Lieutenant-Colonel. The battalion will be composed of men engaged in bridge building, railway construction, roadwork and general construction for overseas service. Mr. Ripley is a member of the Canadian Society of Civil Engineers.

Mr. George McKnight, the new city engineer of Fredericton, N. B., after many years of engineering experience, returns to his native town. Mr. McKnight was born in Fredericton in 1879, and qualified himself for his profession by special courses in military engineering. He started out as chain man on a land surveying party in the province of Quebec; later was rod man on the National Transcontinental Railway; was raised to level in 1905; passed through all the promotion stages, until in 1907 he was appointed resident

Mr. George McKnight.

engineer, which position he held throughout the entire construction of that work. In 1911 he became construction engineer for J. H. Corbett Company, and was at various times in Butlar City, Pa., Wheeler, Va., and Knoxville. Toward the end of the same year he returned to Canada to act as locating engineer for the I. R. C. in Nova Scotia, and early in 1912 entered the employ of the St. John and Quebec Railway Company, which position he resigned on April 15, 1916, to take up his duties as city engineer of Fredericton.

At the annual meeting of the National Brick Company, Montreal, it was reported that while the brick business for the fiscal year ending February 29 was just about as dull as the previous year, there has, however, been some improvement within the past month or two. It is expected that the Ontario National Brick plant, near Toronto, will resume operations shortly, having closed down since the latter part of 1914.

Mainly Constructional

East and West—From Coast to Coast

F. E. Maxwell & Company, contractors, Montreal, Que., have registered.

Builders and Contractors, Limited, Winnipeg, Man., have been incorporated.

The Manitoba Plumbing Company, Limited, has been incorporated with a capital of $5,000, head office at Winnipeg, Man.

Building permits were issued at St. Catharines, Ont., for buildings at an estimated cost of $78,775 during the month of April.

The Fowler Machine Works, Limited, has been incorporated with a capital of ten thousand dollars; head office Vancouver, B. C.

At the annual meeting of the shareholders of the Alberta Sewer Pipe Company, Calgary, P. Turner Bone was re-elected president.

Hon. Mr. Macdiarmid, Minister of Public Works, has decided to adhere to the original Lake Shore route for the Toronto-Hamilton highway.

Building permits in the city of Hamilton, Ont., up to March 31 of this year, total $162,215. This is a decrease from the same period last year of $9,260.

To replace the plant of the Dominion Harvester Company, Medicine Hat, Alta., recently destroyed by fire, a complete new equipment has been ordered.

Building operations in Amherst, Ont., are practically at a standstill. It is stated that as yet there has not been a single house contracted for this season.

Completed plans for the proposed highway work to be done in San Diego County, Cal., under the bond issue which is to be voted upon May 16, involve the expenditure of $2,101,000.

Figures published in the 1915 annual report of the Bureau of Labor show that building permits throughout Ontario declined from 26,253 in 1914 to 21,318 in 1915, and the total cost fell from $68,824,692 to $33,316,942.

In the city of Toronto there were 382 building permits issued during the month of April, representing a total cost in buildings of $457,271, as compared with 193 in the month of March, representing a total cost of $272,240.

The Alberta Farmers' Co-operative Elevator Company have awarded a contract to the Thomas-Jamieson-McKenzie contracting firm of Calgary, to erect seven standard-size elevators in the northern portion of the province.

The Engineers Club, Thorold, Limited, has been incorporated with a capital of $40,000, head office at Thorold, Ont. The object of the company is the promotion of social intercourse and mutual benefit and friendship amongst its members.

The Miramichi hospital at Newcastle, N. B., will be opened next month to the public. This building has a frontage of 144 feet, with an average width of 40 feet. It is a splendidly equipped building, and was erected at a cost of $90,000.

A million-dollar mail order building may be erected by the T. Eaton Company in Toronto. The company are negotiating with the city authorities to obtain for the site an area of land on the lake front from Bay Street to Yonge Street, and it is hoped that the deal will be closed at an early date. The T. Eaton Company are to obtain a lease of the property for 21 years, the rent of which will be $25,000 per annum.

Roadmaking is going on at Niagara camp under the supervision of Lieutenant J. S. McMurray of the Engineer Corps, in preparation for the opening of the camp on the 15th. A new water supply system is also being installed.

Negotiations for the establishment of a new steel plant in Selkirk, Man., are under way. The details in connection with the site have been settled, which is to be on a block of land adjoining the Manitoba Roller Mills. The structure will be of steel.

There has been great activity in building circles in Quebec, P. Q., recently. A large number of building permits have been issued, amongst them being included one to Hon. George E. Amyot for the erection of a $50,000 factory on St. Helene Street.

Trouble was experienced recently in Montreal when the bank of the canal gave way and the water threatened to undermine the city water mains and sewer. It is planned to face the banks with concrete on a solid concrete trench at the bottom of the canal.

Building permits at Welland, Ont., for the month of April this year amount to $20,086, as compared with $10,452 for the same month last year. Total for this year up to the end of April is $30,124, while for the corresponding period last year it was $55,032.

Work on the new C. P. R. station at Quebec, P. Q., is progressing rapidly. One suite of rooms is already completed for the use of the passenger departments. The roofing is practically finished, and it is expected that the whole station will be completed by July.

Chairman Smithers, of the Grand Trunk Railway Company, has written to Premier Borden, suggesting that the Dominion Government take over the Grand Trunk Pacific Railway owing to the inability of the company to meet the debts and deficits on that system.

The city of Charlottetown, P.E.I., propose to install a low lift pumping station, to deal with a million gallons of water per day. The pumps will be driven by oil engines and will distribute the water to the reservoirs. The consulting engineers are R. S. and W. S. Lea, Montreal.

Mr. John Kerr, founder of the firm of J. & J. Kerr, builders and contractors, Petrolea, Ont., died on the 18th inst. He was born in Bonhill, near Glasgow, Scotland, in 1841, and came to Canada in 1847. Mr. Kerr was also largely interested in the refining and production of petroleum.

The United States Government has taken objection to the proposed Chippewa Creek diversion plan for the development of power at Niagara, and have sent a note to the Ontario Government regarding the same, suggesting that the matter be referred to the International Joint Commission for investigation.

A new steel bridge is to be built at Nanaimo, B. C., at an estimated cost of about $5,000, to connect Newcastle Townsite and the main business section of Nanaimo. The City Council have decided to purchase two steel spans which were used in the old Granville Street bridge, Vancouver, for use in its construction.

The old bridge at the foot of Bathurst Street, Toronto, is to be torn down immediately, and a new one erected on the same site, built on concrete abutments resting on bed rock. With the exception of the abutments the bridge is to be entirely of steel. It will have a clearance of 22 feet over the railroad tracks below. It will probably be completed by July of this year.

For the month of April this year the number of building permits issued in the city of Montreal is 220, representing a value of $428,530, as compared with 312 in April, 1915, representing a value of $973,891. There were 438 permits issued up to April 30 this year, value $911,950, while for the same period last year there were 666, value $1,865,827.

The Provincial Lime Company, Limited, with headquarters at Brookville, N. B., have been granted letters patent. The promoters are H. A. Allison, G. E. C. Gandy, R. D. Paterson, S. G. Olive and Harry E. Reardon, all of St. John. The purpose of the company is to carry on a general business of quarrying and manufacturing limestone and all of its products.

The special committee of Parliament formed to pass upon the plans for the reconstruction of the Parliament Buildings, Ottawa, have decided to follow the general plans as submitted by Architects Pearson and Marchand, of Toronto and Montreal. There will be a few minor changes, and it is expected that the contract will be let almost immediately for a sum in the neighborhood of $1,500,000.

Since the first of the month eleven building permits have been issued at the city hall, Peterboro. The value of new buildings represented is about eighteen thousand dollars. The chief among the list is a permit authorizing the erection of an addition to the plant of the Bonner-Worth Company, on McDonnell Street, at an estimated expenditure of ten thousand dollars.

Eighteen tenders were submitted to the Toronto Harbor Commission for the construction of a concrete harbor headwall and cribs, part of the harbor development work from Bathurst to Brock Streets. It has been decided by the Commissioners to award the contract to R. Weddell Company, providing the tenders are in compliance with the specifications, on which report has yet to be made. Some portion of the contract will also probably go to the Russell Company, of Toronto. The whole work, which is to be commenced at an early date, will cost approximately $250,000.

Big structures to cost over $7,000,000 are in the building programme of Toronto, Ont., for the spring and summer. The following is a list of building permits which have been issued or will probably be issued shortly:—

Union Station	$3,400,000
Customs House	1,500,000
Robert Simpson Company warehouse ...	500,000
T. Eaton Company warehouse	500,000
Robert Simpson Company dormitories..	200,000
Princess Theatre	100,000
T. Eaton Co. 4-storey stable	100,000
Majestic Theatre (changes)	50,000
T. Eaton Co. mail order building	1,000,000

The Jefferson highway proposition received hearty endorsation at a recent meeting of the Manitoba Good Roads Association, to which representative men of the city of Winnipeg had been specially invited to consider the question. Mayor Waugh, who seconded the motion put by the Hon. Thomas H. Johnson, Minister of Public Works, emphasized the great advertising value to Winnipeg and the West which would accrue from such direct communication with the whole of the American continent. The Jefferson highway will thus connect Winnipeg with New Orleans, which road will cross a transcontinental, running east and west, and called the "Lincoln," at Des Moines.

The formation of the Fitzhugh-Crowley Corporation, engineers, constructors, and railway specialists, with offices at 60 Broadway, New York, is announced. Mr. E. H. Fitzhugh, the president of the corporation, was formerly vice-president of the Grand Trunk Railway Co., and president and general manager of the Central Vermont Railway. In these capacities he took a prominent part in the great development of railroad facilities in Canada in recent years. Associated with him is Mr. Charles J. Crowley, well known in Toronto, and a railroad engineer of long standing reputation. Mr. Crowley will act as vice-president and chief engineer of the newly formed corporation

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Aylmer, Que.
Plans for the proposed filtration plant are being prepared by F. Meddles, care of Montreal Power Company, Montreal. Approximate cost, $25,000.

Dundas, Ont.
The by-law authorizing the construction of concrete sidewalks at an approximate cost of $5,500 has been carried. The other by-laws for sewers and sewage disposal plant were defeated. Town Clerk, J. S. Fry.

Grand Prairie, Alta.
The Village Council have had plans prepared for a water supply to be taken from Bear Creek.

Markham, Ont.
The Village Clerk, M. White, will receive tenders until May 15th for the construction of approximately 35,000 square feet of concrete sidewalk according to city of Toronto specifications.

Orford Township, Ont.
The Township Clerk, F. Littlejohn, Highgate, will receive tenders until May 20th for the construction of the Butler Drain.

Ottawa, Ont.
The City Council are having plans prepared for asphalt pavement, gutter and catch basins to be constructed on Hinton Avenue. Approximate cost, $8,000. Engineer, F. C. Askwith.

St. Foye, Que.
The Municipal Council propose to expend $15,000 on sidewalks and $100,000 on macadam roads during the season. Secretary, P. N. Robitaille.

Sudbury, Ont.
The Town Council propose to lay bitulithic pavement on a portion of Station Street. Clerk, W. J. Ross.

Tilbury, Ont.
The Town Council are considering the laying of pavement on a number of streets. Clerk, W. H. Hutton.

Tillsonburg, Ont.
The Town Council are considering the laying of crushed stone on the roads at an approximate cost of $5,000. Clerk, A. E. Raynes.

Toronto, Ont.
Works Commissioner Harris has recommended the construction of asphalt pavement to cost about $15,800, and wood block pavement to cost $6,880.

Wellesley Township, Ont.
Tenders on the construction of the Hahn Drain will be received until May 20th by the Township Clerk, Peter Schummer, St. Clements.

CONTRACTS AWARDED

Essex, Ont.
The Town Council have awarded the contract for the supply of one deep well pump, one fire pump and motors to Canadian Allis-Chalmers, limited, 212 King Street West, Toronto. Approximate cost, $3,050.

Ingersoll, Ont.
The Town Council have awarded the contract for the construction of pavements during the year to the Municipal Concrete Construction Company, at 10c per square foot.

North Bay, Ont.
The Town Council have let a contract for the construction of sewers to C. Sandreldi. Approximate cost, $3,500.

Ottawa, Ont.
The City Council have let the contract for the supply of a quantity of watermain to the National Iron Works, Limited, Cherry Street, Toronto.

The contract for supply of sidewalk forms has been let by the City Council to Mussens Limited, 318 St. James Street, Montreal.

Railroads, Bridges and Wharves

Howick Township, Ont.
The Township Clerk, Mrs. C. E. Walker, Gorrie, will receive tenders until May 17th for concrete abutments for two bridges.

Jacquet River, N.B.
Tenders will be received until noon, May 17th, by Hon. John Morrissy, Minister of Public Works, Fredericton, for the superstructure and approaches of a proposed bridge. Plans and specifications at the Provincial Rooms, St. John, and with D. McAllister, Jacquet River, and D. Stewart, M.L.A., Campbellton.

Lobo Township, Ont.
Tenders on the construction of a steel bridge for the Township Council will be received until May 27th by the Engineer, Charles Talbot, London. Estimated cost, $10,000.

Quebec County, Que.
The construction of an electric railway, estimated to cost $150,000, is being considered by the Quebec Railway, Light & Power Company, Quebec.

Public Buildings, Churches and Schools

Amherst, N.S.
The Town Council propose to remodel the County Academy and install a heating system. Clerk, W. F. Donkin.

Brampton, Ont.
Revised plans are to be prepared for the proposed addition to the Sunday School of the Methodist Church, and new tenders will be called. Architect, Hartley Galloway, 79 Adelaide Street E., Toronto. Approximate cost, $10,000.

Calgary, Alta.
The Hospitals Board are considering the erection of an addition to the General Hospital to accommodate 100 nurses. Approximate cost, $60,000.

Dundas, Ont.
The by-law to authorize the erection of a High School at an approximate cost of $35,000 has been defeated.

Haileybury, Ont.
The High School Board will receive tenders until May 15th for the erection of the School of Mines Building. Plans and specifications at office of the Secretary, J. H. Shibley, Box 179, and at the T. & N. O. Station. Approximate cost, $20,000.

Hazenmore, Sask.
The Trustees of School District 3225 have been empowered to borrow $6,000 for the erection of a two-roomed brick school. Treasurer, H. Whiteley, Hazenmore.

London, Ont.
The Trades & Labor Council propose to build a Temple at an approximate cost of $45,000, and will have plans prepared. Particulars from James Hussley, 241 Colborne Street.

McGregor, Ont.
The Catholic Trustees are considering the erection of a school, at an approximate cost of $10,000. Particulars from Father J. A. Pinsonneault.

Ottawa, Ont.
The Department of Public Works have included in their supplementary estimates the sum of $240,000 for a new roof for the East Block. Secretary, R. C. Desrochers.

Portage La Prairie, Man.
The by-law to authorize the raising of $64,500 for the erection of a school has been defeated.

St. Raphael D'Aston, Que.
Work is about to start on the erection of a Presbytery for the Parish. The general contract will probably be let to La Cie. Ouvriere, St. Raphael d'Aston. Approximate cost, $8,000. Architects, Louis Caron & Fils, Nicolet.

Swanson, Sask.
The Trustees of Knight School District 1756 have been authorized to borrow $6,000 for the erection of a school. Treasurer, W. G. Grigg, Swanson.

Tavistock, Ont.
The ratepayers have authorized the $9,000. Tenders will probably be called shortly. Architect, J. S. Russell, 21 Downie Street, Stratford.

Victoria, B. C.
The School Board are having plans drawn for a school to be built on King's

Road, at an approximate cost of $25,000. Architect, C. E. Watkins, Green Block. Brick construction.

CONTRACTS AWARDED

Cochrane, Ont.
The general contract for the erection of a school has been let to Oliver, Edward & Company, care of W. D. McDouglas, Secretary to the School Board. Approximate cost, $40,000. Architects, Angus & Angus, North Bay.

Dover Township, Ont.
The contract for masonry, carpentry, plastering and painting required in the erection of the Presbyterian Church has been awarded to Harry Rayment, 155 Grand Avenue W., Chatham, at $4,813.

Havre au Bouche, N.S.
The contract for exterior work required in the erection of a church for the Roman Catholic Congregation has been awarded to Landry & McGillivray, Antigonish. Approximate cost of building, $25,000.

Kingston, Ont.
Work has been started on the erection of a school for the Public School Board, and the plumbing contract has been let to Taylor Brothers, Almonte.

Montreal, Que.
The contract for carpentry required in the erection of a Presbytery for Ste. Catharine Parish has been let to R. Marsolais, 319 Beaudry Street, the roofing, heating and plumbing to T. Lessard & Sons, Ltd., 191 Craig Street E., plastering to J. Chamberland, 553 Durocher Street, and electrical work to L. Ortiz, 376 Fabre Street.

The general contract for the erection of a Presbytery for the Trustees of Ste. Catherine Parish, 408 Amherst Street, has been awarded to O. Archambault, 610 Parc Lafontaine Street. Approximate cost, $28,000.

The general contract for the construction of a basement for the proposed Church of St. Peter and St. Paul has been awarded to Prima Corbeil, 382 Fabre Street.

Mt. Dennis, Ont.
The following contracts have been let in connection with the school now being built for the Trustees of School Section 28:—roofing, W. E. Dillon Company, Limited, 183 George Street, Toronto; terrazzo floors, Italian Mosaic & Marble Company, College Street, Toronto; electrical work, W. F. Moon & Company, 1724 Dundas Street, Toronto; painting, Fell Brothers, 44 McMurray Street, Toronto.

Ponteix, Sask.
The general contract for the erection of a church and rectory for the Roman Catholic Congregation has been awarded to the Poole Construction Company, Limited, Smith and 12th Streets, Regina. Approximate cost, $20,000.

Quebec, Que.
The Commercial Academy, Cook St., have awarded the general contract for the erection of a College on Chauveau Street to Jinchereau & Lamonde, 325 Richardson Street, at $260,000.

St. Antoine de Bienville, Que.
In connection with the erection of the Parish Church, the masonry contract has been let to Paquet & Godbout, St. Hyacinthe.

In connection with the Parish Church, the carpentry contract has been let to Paquet & Godbout, 21 William Street, St. Hyacinthe, painting to O. Lachance, 25 Eden Street, Levis, and electrical work to P. P. Giguere, 55 Des Fosses Street, Quebec.

St. Evariste de Forsythe, Que.
The general contract for the erection of a school has been awarded to Albert Langelier, St. Victor de Trung. Approximate cost, $10,500.

St. Therese, Que.
The contract for the erection of a convent for the Rev. Sisters of the Congregation Notre Dame has been let to Beausejour, Letourneau & Company, Grand'Mere, Que. Brick, stone and concrete construction. Estimated cost, $56,000.

Toronto, Ont.
The Separate School Board have let the following contracts in connection with St. Monica's School:—masonry, M. Manley, 1058 College Street; carpentry, D. & M. J. Madden, 552 Adelaide Street W.; roofing, A. Ryan, 962 Bathurst St.; steel work, McGregor & McIntyre, 1139 Shaw Street; plumbing, W. J. McGuire, Limited, 91 James Street; heating, T. E. Regan, 95 Booth Avenue.

The following contracts in connection with the addition to St. Peter's School have been let by the Separate School Board:—masonry, John McGloe, 285 Sherbourne Street; carpentry, D. & M. J. Madden, 552 Adelaide Street West.

Business Buildings and Industrial Plants

Aylmer, Que.
The Fair Association contemplate the erection of Fair Buildings, estimated to cost $4,000. Secretary, F. Duma.

Banff, Alta.
Harold S. Johnston has been appointed Architect for the proposed block to be erected on Banff Avenue for R. G. Brett. Estimated cost, $20,000.

Barriefield, Ont.
The Department of Militia have received tenders on the erection of a number of frame buildings at the Camp. Approximate cost, $16,000.

Crampton, Ont.
John Jenkins, Avon Gravel Road, Ingersoll, is considering the erection of stock barns and a residence, estimated to cost $4,500.

Dresden, Ont.
Thomas Pavy has commenced the erection of stock buildings, estimated to cost $3,200. Steel and cement construction.

Greenock, Ont.
Andrew Watson, R. R. No. 1, Paisley, is preparing plans of a stock barn, to cost about $3,000. Frame and concrete construction.

Halifax, N.S.
Bonds Limited, Barrington Street, are having plans prepared for remodelling a restaurant building, estimated to cost $20,000. Architect, S. P. Dumaresq, St. Paul Building. Reinforced concrete and brick construction.

Hamilton, Ont.
George Hill, 21 Vine Street, is receiving tenders on steel work and roofing required in connection with the stable which he is building.

Malden Township, Ont.
Ernest Shaw, Concession 3, Amherstburg, Ont., will shortly commence the erection of a stock barn. Estimated cost, $3,000. Frame and concrete construction.

Montreal, Que.
Thomas Lamb, Architect, New York, is preparing plans for a theatre to be built for G. Rabinovitch, 532 St. Lawrence Boulevard. Approximate cost, $250,000.

H. Morgan & Company, 16 Beaver Hall Hill, are about to erect a garage, estimated to cost $10,000. Brick and concrete construction.

New Hamburg, Ont.
Work has been started by H. Deichert on the erection of an addition to a store, estimated to cost $3,000. Brick and concrete construction.

Ottawa, Ont.
The Burrows Refining Company, 629 Wellington Street, are about to commence the erection of a nickel refinery, estimated to cost $6,000. Ironclad and frame construction.

Prince Edward Island, Ont.
William Lockhart, Ruscomb, Ont., is considering the construction of a plant for the manufacture of brick and tile. Estimated cost, $10,000.

Quebec, Que.
E. Julien & Company, 1230 St. Valier Street, have commenced the erection of a store, estimated to cost $3,000. Brick and concrete construction.

Work has been started by Bedard & Kippan, 12 Cartier Avenue, on the erection of a theatre on St. John Street. Estimated cost, $6,000.

St. Clothilde, Que.
Omer Bergeron is about to start work on a sawmill, estimated to cost $5,000. Frame and metal construction.

Sudbury, Ont.
V. L. Morgan is preparing plans for stores to be erected for J. P. Coulson. Brick and concrete construction. Approximate cost, $4,000.

Toronto, Ont.
W. G. Hunt, Architect, 12 Queen St. E., is preparing plans for two stores to be erected on St. Clair Avenue W., at an approximate cost of $6,000. Tenders will be called shortly. Brick construction.

C. J. Gibson, Architect, 53 Yonge St., will receive tenders until May 13th on all trades required in the erection of an office and warehouse for William Long, 406 Yonge Street. Brick and steel construction. Approximate cost, $25,000.

The Sun Beam Lamp Company, Dufferin Street, have had plans prepared for a storage building, to cost about $17,000. Brick and steel construction.

The Board of Control will receive tenders until May 23rd for the erection of an addition to the St. Clair Avenue Car

Barns, estimated to cost $25,000. Steel and frame and brick construction. Plans at Room 311, City Hall.

Plans have been prepared for an addition to the premises of the McClary Manufacturing Company, 177 King St. W. Brick construction. Approximate cost, $3,500.

The T. Eaton Company are negotiating with the Harbor Commissioners for a site for the erection of a warehouse. Estimated cost, $1,000,000.

The Toronto Harbor Commissioners are building a machine shop, estimated to cost $15,000. Corrugated iron and brick construction.

Whitby, Ont.
John T. Hornsby is preparing plans for two stores to be built on Brock Street for W. J. H. Richardson. Fireproof construction. Estimated cost, $5,500.

Windsor, Ont.
G. Jacques & Company, Boug Block, will receive tenders until May 30th for the erection of a block of stores and flats on Dougal and Pitt Streets for Herman Benstein, 132 Goyeau Street. Brick and concrete construction. Estimated cost, $20,000.

Winnipeg, Man.
The Department of Public Works, Ottawa, have included in their supplementary estimates the sum of $500,000 for the erection of a grain elevator.

CONTRACTS AWARDED

Halifax, N.S.
The contract for all work except plumbing and electrical work required in alterations to a theatre for the Academy of Music, Limited, has been awarded to S. M. Brookfield Limited, 58 Granville Street. Approximate cost, $30,000.

The contract for brick work required in the construction of a gas plant for the Halifax Electric Tram Company has been awarded to MacKenzie & Murphey, Sydney, N. S., and the contract for supply of about 1,000,000 brick to the Nova Scotia Clay Works, Ltd., Halifax.

Hamilton, Ont.
In connection with the erection of an addition to the premises of the Zimmerman Manufacturing Company, the contract for roofing has been awarded to John Riddle & Son, 12 Ferguson Avenue N., heating and plumbing to W. J. Walsh, 215 King Street E., and electrical work to Snyder Brothers, 37 King William Street.

Maisonneuve, Que.
The general contract for the erection of an office and residence for Abel. Fortin & Cie., Desjardins Street, has been let to Arsene Croquette, 170 Bourbon Street. Brick construction. Approximate cost, $3,500.

C. Davison, Cullen; Landshut, $4,000, John Betz, Jr., Langenburg.

St. Foye, Que.
The Municipal Council are considering the installation of an electric lighting system, estimated to cost $15,000. Secretary, P. N. Robitaille.

Stratford, Ont.
The Town Council are considering extensions and improvements to the electrical system, estimated to cost $33,000. Clerk, R. R. Lang.

Wyoming, Ont.
A by-law has been carried authorizing the installation of a hydro system, at an approximate cost of $6,500. Town Clerk, H. G. Taylor.

Fires

Bentley, Alta.
Business block owned by J. G. Bliss. Loss, $15,000.

Effingham, Ont.
Residence and barn owned by Peter Ward. Loss, $5,000. Owner may rebuild.

Gourock, Ont.
Store and Post Office owned by Alexander Ireland. Loss, $3,500. Owner contemplates rebuilding.

Levis, Que.
Store and residence of G. E. Couture. Loss, $25,000. Will be rebuilt.
Residence owned by T. Bissonnette, 129 Cote du Passage. Loss, $5,000.

Maisonneuve, Que.
Residence owned by Walter Reed, 135 De Beaujeu Street. Loss, $3,000. Repairs will be made.

Tenement buildings owned by Reed & Gratton. Loss, $26,000. Will be rebuilt.

Medicine Hat, Alta.
Milling plant of the Lake of the Woods Milling Company. Loss estimated at $500,000.

Okanagan Falls, B.C.
Post Office owned by the Department of Public Works, Ottawa. Loss, $4,000.

Orillia, Ont.
Skating rink, owned by F. A. Doolittle. Loss, $10,000.

Owen Sound, Ont.
Plant of the Union Cement Works Company damaged. Loss, $4,000.

Pennfield, N.B.
Residence and barn owned by Charles Gillespie. Loss, $5,500.

St. Boniface, Man.
Mills of the Rice Malting Company of Canada. Loss, $300,000.

St. Catharines, Ont.
Business owner by the Dominion Bank of Canada. Loss, $20,000.

Verdun, Que.
Residence owned by T. Lanquette, 317 Gertrude Street. Loss, $5,000. Repairs by day labor.

Winnipeg, Man.
Printing and engraving plant of the Stovel Company. Loss estimated at $500,000.

Miscellaneous

Chatham, Ont.
The Union Natural Gas Company, Chatham, propose to relay a 10-inch high pressure gas main from the wells at Port Alma to Sombra, a distance of forty miles. Approximate cost, $300,000.

Frontenac County, Ont.
Tenders on the erection of a wooden lighthouse and dwelling at Burnt Island will be received until noon, May 17th, by the Deputy Minister of Marine, Ottawa. Plans and specifications at the Department, the Department Agency, Prescott, and the Post Offices at Brockville, Gananoque, Belleville and Kingston.

North Bay, Ont.
The City Engineer, H. J. McAuslan, will receive tenders until noon, May 15th, for the supply of about 3,000 feet of 6-inch and 630 feet of 4-inch cast iron watermain and specials.

Ottawa, Ont.
The Ottawa Improvement Commission, 110 Wellington Street, are having plans prepared for lavatories to be built in Rockliffe Park, at an approximate cost of $10,000. Brick and concrete construction.

Sault Ste. Marie, Ont.
The Algoma Steel Corporation are in the market for quantities of brick.

CONTRACTS AWARDED

Westmount, Que.
The City Council have awarded the following contracts for supplies:—cement, Webster & Sons, Ltd., 31 Wellington Street, Montreal; cement and vitrified sewer pipe, tile and inverts, W. & F. P. Currie & Company, 345 St. James Street, Montreal; brick, Laprairie Brick Company, Victoria Square, Montreal, and St. Lawrence Brick Company, 71 St. James Street, Montreal; vitrified sewer pipe, Hamilton & Toronto Sewer Pipe Company, Dominion Bank Building, Toronto.

Recruiting from Munition Factories

A large Canadian manufacturer engaged in completing, with feverish haste, a big munitions contract, stated within the last couple of days that pressure had again been brought to bear on one of his best mechanics to drop his work and join the fighting ranks. In spite of all the arguments of the employer the man had gone. This is only one instance of many we know of and doubtless of many hundreds that have not come to our attention.

How much longer can our government sit inanely by and watch this gradual process of demoralization and disintegration without taking any steps to prevent or remedy it? If our government is so lacking in the type of men who have the ability to conceive and carry out the necessary organization of our man power, or if they are so held in by the traditional curse of political exigency, can they not at least hand the matter over to some responsible group of business men? Such men, organizers both by training and natural ability, to be had in numbers for the asking, who would consider it a disgrace to accept salary or commission, who would honor themselves by being allowed to express their deep loyalty in placing their services at the disposal of the Empire—many of these superb business men in Canada to-day are chafing at their inability to assist in this war and impatiently cursing our government for their inactivity and all too apparent helplessness in grappling with some of our big problems. Why don't we organize? is heard in every quarter. Are our resources so much more than adequate for the demands to be made upon them that we can afford to fritter them away?

It is an old saying that constant dropping water will wear away even a stone, and it is not impossible that constant urging and dinning, in these pages, may yet play some small part in arousing our government to action along the line of organizing our men power and our other big resources that the greatest amount of work may be accomplished with the least possible expenditure of energy. It's a business man's job, of course, but business men by the score are vainly offering their services. Will not the authorities at Ottawa admit, soon, that the conduct of the details of a great war is not in their line and pass the work along to others who are as capable as they are eager to undertake it?

The Cause and Prevention of Dry Rot

From time to time inquiries are received at this office asking for information on the cause and prevention of dry rot in mill construction. The Contract Record has published occasional short items on this subject, but in the hope that it may be of assistance and to more fully explain the matter a fairly comprehensive article on dry rot appears elsewhere in this issue.

Rotten timber is due to decomposition brought about by dampness, which generally proceeds by the emission of carbonic acid gas and hydrogen. Timber rot may be either wet or dry; the former usually occurs in the presence of moisture where gases emitted may escape. Dry rot, on the other hand, is found in confined places where the gases which are emitted cannot escape but enter into some new combination aiding in the formation of fungi, a parasitic vegetable growth which feeds upon and destroys the timber. This fungus growth is commonly termed as punk, toadstools, or dry rot—terms which are exceeding vague and indefinite.

The term, dry rot, is used to signify broadly the following fungi: Merulius lachrymans and other members of the Merulius genus; Coniophora cerebella (or Coniophora peuteana). These dry rot fungi have two methods of reproduction—by the common reproductive body corresponding to the seeds of the higher plants, which is called a spore, a microscopic organism brown in color, which is produced in millions on the surface of the plant; or by the growing plant separating into small sections which grow again under suitable conditions.

Dry rot is usually caused by moisture and the lack of ventilation, or exposure to alternate wet and dry spells, and the use of green sap wood. It is dangerous, as is known, in that it reduces the cohesion of the wood fibre, ultimately reducing it to powder. Dry rot is best prevented by using seasoned heart wood and providing good ventilation, or by treating it with some wood preservative such as creosote. After the growth is started it may, if not too far advanced, be checked by heat and ventilation. Merulius lachrymans is particularly sensitive to heat, a temperature of 108 degs. F. for three hours or 115 degs. F. for one hour being sufficient to kill it. It is also killed by complete dryness. Antiseptic treatment is practically the only procedure to adopt for lumber of doubtful durability or for lumber that is to be placed in a position suitable for the generation of dry rot, or for wood previously exposed to dry rot. Much valuable information on dry rot, conditions suitable to its growth, means of prevention, etc., will be found in the article mentioned above, which should prove of value to owners or builders who have met with this trouble.

What is a Pavement?

What types of roadway surfacings should properly be classified as pavements?

This query has been suggested recently by an examination of data on street paving in a number of cities. The figures referred to included statements showing the total mileage of paved streets and the mileage of each type of surfacing in each of a number of cities. Some street officials classed streets surfaced with gravel and water-bound macadam as paved streets, while others excluded these two surfacings and, in a few cases, others.

The dictionary definition of a pavement is: "That with which anything is paved; a floor or covering of solid material, making a hard and convenient surface for travel; a paved road, sidewalk, or other surface." The verb, pave, is defined as follows: "To lay or cover with stone, brick, or other material, so as to make a firm, level, or convenient surface for travel; to floor with brick, stone, or other solid material; to cover as a pavement." These definitions are sufficiently broad to permit the inclusion of gravel, water-bound macadam, sand-clay, and various other surfacings as pavements.

On the other hand, the American Society of Civil Engineers' Special Committee on Materials for Road Construction and on Standards for their Test and Use has defined a pavement as follows: "The wearing course of the roadway or footway, when constructed with a cement or bituminous binder, or composed of blocks or slabs, together with an cushion or binder course." Under this definition gravel, water-bound macadam and some other types of surfacings would not be pavements.

While the dictionary definition and the one proposed by the committee are not comparable, they reprecent exactly the difference of opinion that apparently exists among street officials and engineers. Doubtless the committee's definition merits the greater consideration, for it was made by experts, while the dictionary definition was not. Certainly it seems to represent the current usage of engineers and technical writers.

Although the question is perhaps of minor importance, it is worthy of consideration, for the subject of road building terminology needs standardization.—Good Roads.

Hints on Sewer Construction

Mr. W. W. Horner, engineer in charge of division sewers and paving, St. Louis, Mo., in addressing the 12th annual convention of The American Concrete Institute at Chicago on reinforced concrete in sewer construction, recommends to engineers and contractors the following prescription for sewer construction:—

(1) Use the best grade of concrete and considerable excess of mortar. (2) Do not work concrete at more than 450 lb., unless the construction conditions are to be exceptionally favorable. (3) The concrete cover outside of the steel should be at least 2 in. (4) Use a minimum thickness of concrete of about 9 in., unless the work is close to the surface, or is to be built under very favorable conditions, and increase this minimum and also the cover over the steel if the conditions are likely to be very unfavorable. (5) Specify the setting of the reinforcement with especially designed holders. These might be made of cast iron and left in the concrete. (6) If there is any possibility that the trench will be very wet or mucky, provide for a sub-case of concrete and provide means of keeping the trench work away from the work, if possible. (7) To secure a concrete that will flow into place with the least assistance, a specification for a two-and-a-half or a three minute mix should be seriously considered, as might also the use of hydrated lime. This would naturally result also in a denser and more waterproof concrete and might be a very considerable factor in prolonging the life of the reinforcement. (8) Provide for a lining of vitrified brick for the invert, or at least provide an excess internal area to allow for such a lining at some later date. This is of more importance in maintenance than in construction, as under average conditions it is easier to obtain a reasonably smooth invert with the brick than to attempt to finish the concrete itself. (9) Specify cold weather methods. Concrete can be placed satisfactorily and economically at even a zero temperature, if proper precautions are taken. It should be noted, however, that it is quite easy to overheat the finished concrete and to drive out a portion of the water.

A Union Station for Montreal

The Montreal Central Terminal Company is reviving an old and ambitious scheme for a Union station. Mr. C. N. Armstrong has placed before the Council the outline of the plan, which includes the construction of a tunnel under the St. Lawrence, thus connecting the north and south shores. The station is to be built in a central portion of the city, and is estimated to cost about 35 million dollars. It would give accomodation for all the lines entering the city, connection being made with the Windsor Station of the C. P. R. The Bonaventure Station of the Grand Trunk would be converted into a freight depot. Such a scheme would settle the question of level crossings, which has been several times before the Railway Commission in connection with the obligation of the city to bear a portion of the raising of the tracks of the Grand Trunk. The proposal is that all the lines running into the union station should be electrified. The promoters state that application is to be made to the Railway Commission and that the capital will be privately subscribed.

Dry Rot Menace in Factory Timbers

Conditions Favorable to the Growth of Common Timber-Destroying Fungi—Discussion of Methods of Preventing Their Development

All wood is almost equally durable under certain conditions. Kept absolutely dry or submerged it lasts indefinitely, but under other conditions the best wood may decay very rapidly. Dryness and good ventilation are the best guarantees of prevention from decay in timber used in general construction. Water also seems to act as a preservative, as some kinds of timber totally and constantly submerged in water not in motion, have been found to remain practically sound for hundreds of years.

The general causes of decay in timber are the presence of sap, exposure to alternate wet and dryness, or to moisture accompanied by heat and lack of ventilation. Rotten timber is due to decomposition or putrefaction, generally occasioned by dampness, and which proceeds by the emission of gases, chiefly carbonic acid gas and hydrogen. There are two kinds of rot to which wood work in a building is subject, dry rot and wet rot. The chief difference between them seems to be that wet rot occurs where the gases involved can escape. By it the tissues of the wood, especially the sappy portions are decomposed. Dry rot, on the contrary, occurs in confined places where the gases cannot escape, but enter into new combinations, forming fungi, which feed upon and destroy the timber.

Dry rot is generally caused by lack of ventilation; confined air, without much moisture, encourages the growth of the fungus, which eats into the timber, renders it brittle and so reduces the cohesion of the fibres that they are reduced to powder. It generally commences in the sapwood.

Dry rot is especially dangerous in that it not only eats up the entire timber in which it originates, but the germs of the fungi producing it spread themselves to all adjacent woodwork without necessary contact between the diseased and the sound wood.

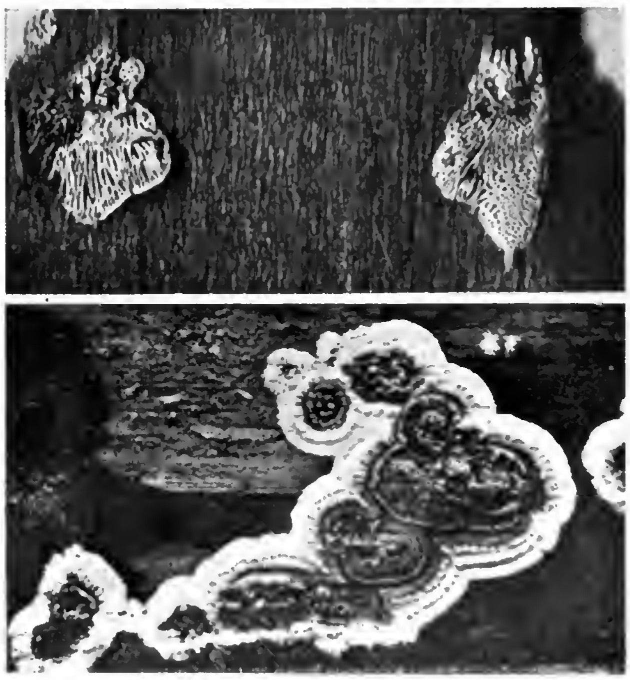
There are but few common or popular names for fungi, and the few there are, such as dry rot, punk, toadstools, etc., are exceedingly vague and indefinite. The Latin names are commonly used in scientific literature. Their use implies an exact identification. "Dry rot" is used to signify broadly the following fungi: Merulius lachrymans and other members of the Merulius genus; Coniophora cerebella (or Conicophora puteana). The name "Polyporus family" (fungi having many pores) has been used to include broadly any of the pore fungi having pores or holes of various sizes and shapes in the fruiting surface. Fruiting fungi can be easily identified but it is impossible to positively identify the young sterile growth.

The conditions required for the germination or growth of the merulius lachrymans have often seemed mysterious. The spores germinate in an eccentric manand frequently refuse to grow to fruition on their customary host in artificial cultures. Dry rot fungi have two methods of reproduction and can remain a long time in a resting state. The common reproductive body, corresponding to the seed of higher plants, is called a spore, and grows over the surface of the plant. Spores are brown in color and therefore may be easily distinguished from the surrounding sterile growth. They are microscopic in size, being about .0004 of an inch long and .0002 of an inch broad. A single plant produces many millions and their small size allows them to float a long distance in the air.

Under unfavorable conditions for growth, such as insufficient moisture, some of these destructive fungi assume a form of reproduction different from that by which they ordinarily spread. In this form, the growing plant separates into small sections which can sprout and grow again when favorable conditions arise. It can remain in this resting state for a considerable time in air dry wood.

Rot in wood was originally supposed to be a chemical action similar to rusting of iron, and the delicate lace-like plants, tough brackets, or brown leathery growths were supposed to be attracted by the decayed wood, rather than being the cause of the rotting. The chemistry of the rotting process is not well known even at the present time. It is probable that there is some chemical action in addition to the life progress of the fungus through the wood cells. It is noted in blocks of sound wood, in which fungus has been cultivated, that when the fungus is freshly removed from the moist wood, it has the appearance of being bright and sound as ever; but, after being left in a dry atmosphere for a time, the wood shrinks and forms the characteristic brown, cracked and powdery material which is familiar as rotted wood.

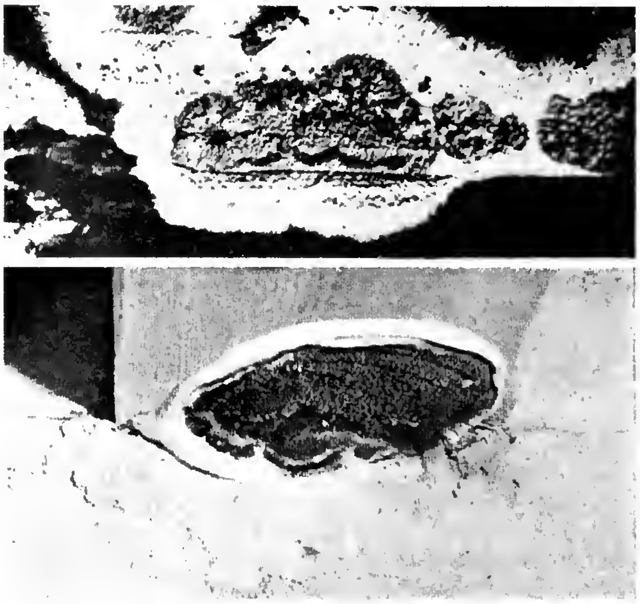
Without doubt, the fungus ceases to make any vital progress very soon after drying commences, and the final browning and powdering is brought about by oxidation by the air, assisted by certain organic enzymes, either already present in the wood cells or formed by the activity of the fungus.



Types of fungi—Upper, Lenzites sepiaria growing on a spruce roof. Lower, Coniophora with fruit.

In most cases, the rotting found has taken place rapidly, instead of having been, as sometimes supposed, a slow continuous process similar to the rusting of iron or the weathering of stone. Sometimes after the timber has been partly destroyed, the fungus growth is arrested, leaving sufficient strength to carry the load, and, when the rotted timber is discovered years later, it is assumed that destruction has been progressing slowly since the erection of the building.

Dry rot progresses much faster in summer than in winter in an ordinary building which is heated and thus has its air made relatively dry during the winter



Types of fungi—Upper, Merulius lachrymans with fruit—Lower, Merulius lachrymans growing on a pine beam.

months. Moisture produces the condition most favorable for rapid rotting, the rate of decay being dependent on the relative humidity. Relative humidity is defined as the ratio of the amount of moisture present at any given time to complete saturation, or the per cent. of saturation, of the air at the given temperature.

The relative humidity of air in a room, or basement, sometimes is very different in places only a few feet apart. The difference of a few per cent. in the relative humidity is sometimes sufficient to stop the growth of certain fungi.

The effect of moisture is not limited to the air, but extends to the interior of the timber. Weaving room and paper mill timbers are frequently found with a sound shell both inside and out, and the interior entirely rotted away.

That wood destroying fungi cannot grow under water, or with the wood cells filled with water, is proved by many examples. One of the fine points in the successful design of wood stave pipe for conveying water under pressure, is to design its staves so thin that the pressure will keep the wood saturated; then, it is claimed, it will last indefinitely without decay. Wood of great antiquity has been found buried in clay in a perfect state of preservation.

Dry rot, or merulius lachrymans fungus, will grow on the surface of wood at atmospheric saturations from 96 per cent. to 100 per cent. It will grow inside of large beams of susceptible material at a much lower percentage of atmospheric saturation. A possible source of moisture for supplying the requirements of a fungus growing inside a large beam is the decomposition of the beam itself. Chemical analysis shows rotted wood to contain relatively less hydrogen and more carbon than the original sound wood; this would indicate that the hydrogen part of the cellulose or lignine molecule, is more strongly attacked than the carbon part. This would result in the formation of water, if the decomposition is accompanied by oxidation.

The dry rot disease is chiefly carried by direct contact, but living spores carried in the air can take root when they find a favorable resting place. Fungi are frequently carried in lumber and spread by placing it in large piles with scant ventilation.

In examining a building affected with dry rot, the extent of the rotting can generally be estimated approximately by boring test holes into the beams and columns at frequent intervals. If the material is badly rotted, the borings brought out will be in the form of brown powder or mud, according as the wood is wet or dry.

Hammering on the timber with a machinist's hammer is another method frequently adopted. In this way the outer shell of apparently sound beams has been broken through showing the entire destruction of the interior. To determine whether the rot is still alive is frequently a complicated matter. If it is growing on the surface of the wood, the fresh growth of lace-like plants is significant, but the more frequent condition is where the dry rot fungus is growing inside the wood with no outward manifestation. In this case, a strong indication of living fungus is the moist appearance of a freshly cut section.

Prevention of Rot

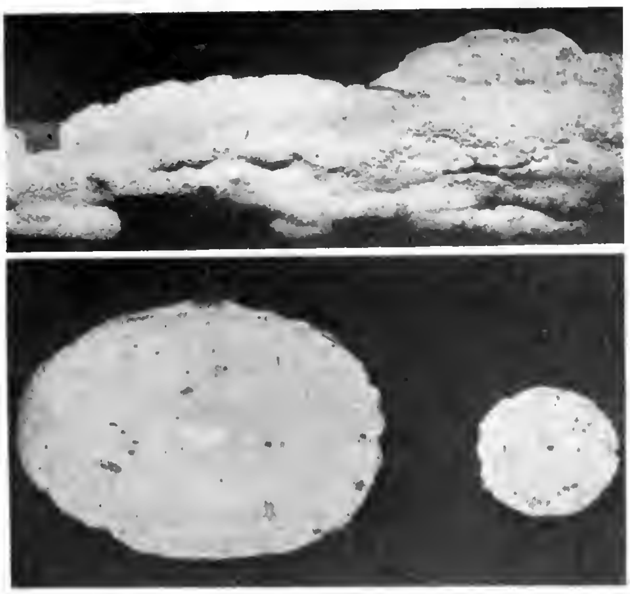
For ordinary building construction the best means to preserve timber from decay is to have it thoroughly seasoned and well ventilated; and if these conditions are secured, there is little danger of rot. Ventilation is generally the first preventative measure suggested. Dry wood, which is placed in an atmosphere well below the moisture requirements of a given fungus, is undoubtedly incapable of infection with that fungus; but, ventilation does not necessarily cause drying, as the wood will become drier or wetter depending on the relative humidity of the air with which it is ventilated. Therefore timber ventilated with moist air may have its rate of rotting accelerated rather than retarded.

A heavy coat of paint may retard or accelerate the rate of rotting, depending upon whether it prevents the wood from absorbing or giving up moisture. The condition most commonly met, in which paint causes rotting, is when it is applied to green timber saturated with water. With dry sound timbers, which are to be placed in a moist atmosphere, a paint will doubtless prove beneficial in proportion to its waterproofing qualities.

It is probable that a very important factor in the resistance of several woods to fungus growth is the presence of some moisture resisting material, such as resin, which prevents sufficient water from being absorbed under the ordinary conditions of atmospheric humidity for the requirements of common fungi. On the other hand, the presence of hygroscopic materials in wood cause it to absorb large amounts of water, in order to maintain equilibrium with the atmospheric humidity, and would render it more susceptible to attack by fungi. "Cold water" or "fireproofing" paints, containing hygroscopic materials, therefore accelerate the progress of rot.

Heat and drying are useful in stopping rot. Often an infected building can be sterilized by skilful use of its own heating system. Merulius lachrymans is particularly sensitive to heat, a temperature of 108 degrees F. for 3 hours or 115 degrees F. for 1 hour, being sufficient to kill it. It is also killed by complete dryness; but ordinary air drying does not kill it. Large beams and girders are better built up and cased, and posts should be bored longitudinally. But even columns with holes through them and the sections of built up beams must be given a chance to season, as the common custom of boring green or wet columns just before they are put in place in a building, and using damp or green lumber for built-up beams, leaves ideal places for the growth of fungus. Holes in columns, moreover, have the objection that they form a convenient passageway for the fungus to move rapidly from floor to floor in a diseased building.

The causes of natural resistance to fungi in wood are obscure and have been investigated but little. Heartwood is generally much more resistant to fungi than sapwood. The presence of starches and sugars in the sapwood, which serve as foods for fungi, as well as the greater water content, are probably the chief causes of its more rapid destruction, while the resistance to water of the heart resin and the antiseptic action of tannin are undoubtedly important functions in the resistance of the heartwood. The limiting power of resin is not absolute, but varies with the moisture, variety of fungus and time of exposure. The resistance of wood to decay does not depend upon any one factor, but is the result of many heterogeneous components acting together.



Types of fungi—Upper, Trametes serialis on a basement beam—Lower, Fomes roseus, a hard rose tinted fungus.

Antiseptic treatment is the only practicable procedure with lumber of doubtful durability because of porosity, light weight, sap or previous exposure to infection, or when it is to be used in a moist place. Much attention has been given to the treatment of railroad ties, posts, etc., but very little study in the past has been given to the treatment of mill timber. The increased life of railroad ties, treated with an antiseptic of 10 lbs. of creosote per cubic foot, is given by the U. S. Forest Products Laboratory as from eight to fifteen years.

The problem of treating timber for factory construction however, is different from that of railway ties or posts. Increased fire hazard, resistance to paint, and a disagreeable odor, are items to be considered, which are of no importance in the case of ties or posts. For this reason, the numerous creosote and tar compounds are often unsuitable. The metal salts, such as corrosive sublimate, are preferable according to all the evidence thus far available. Coal tar compounds are more used for preservative treatments of wood than all other materials together; they act mechanically and chemically, serving as waterproofing as well as antiseptics. The penetration of antiseptics has been increased by the use of vacuum and pressure processes, applied in closed tanks.

Various observations show that liquid oils do not thoroughly waterproof wood and, from all evidence obtainable, fungus is able to thrive about the same on oil soaked wood as upon wood without it.

In building a paper mill or weaving mill, or any structure in which the humidity will be high, antiseptic treatment is well worth its cost with any timbers now available.

Summing up the question of dry rot, and its menaces to timber structures. The variety of fungi causing destruction of buildings are apparently few, and their habits are controlled chiefly by the supply of moisture and the temperature. It is well worth the cost to heat the building as soon as possible after completion. Buy heartwood whenever possible and subject it to a chemical treatment of sufficient strength to kill any latent fungi that it may contain, and to protect the surface from future attack. Also provide good ventilation, and the menace to the safety of structures by dry rot will be largely prevented.

C. P. R. Dam at Moose Jaw Slides on Base

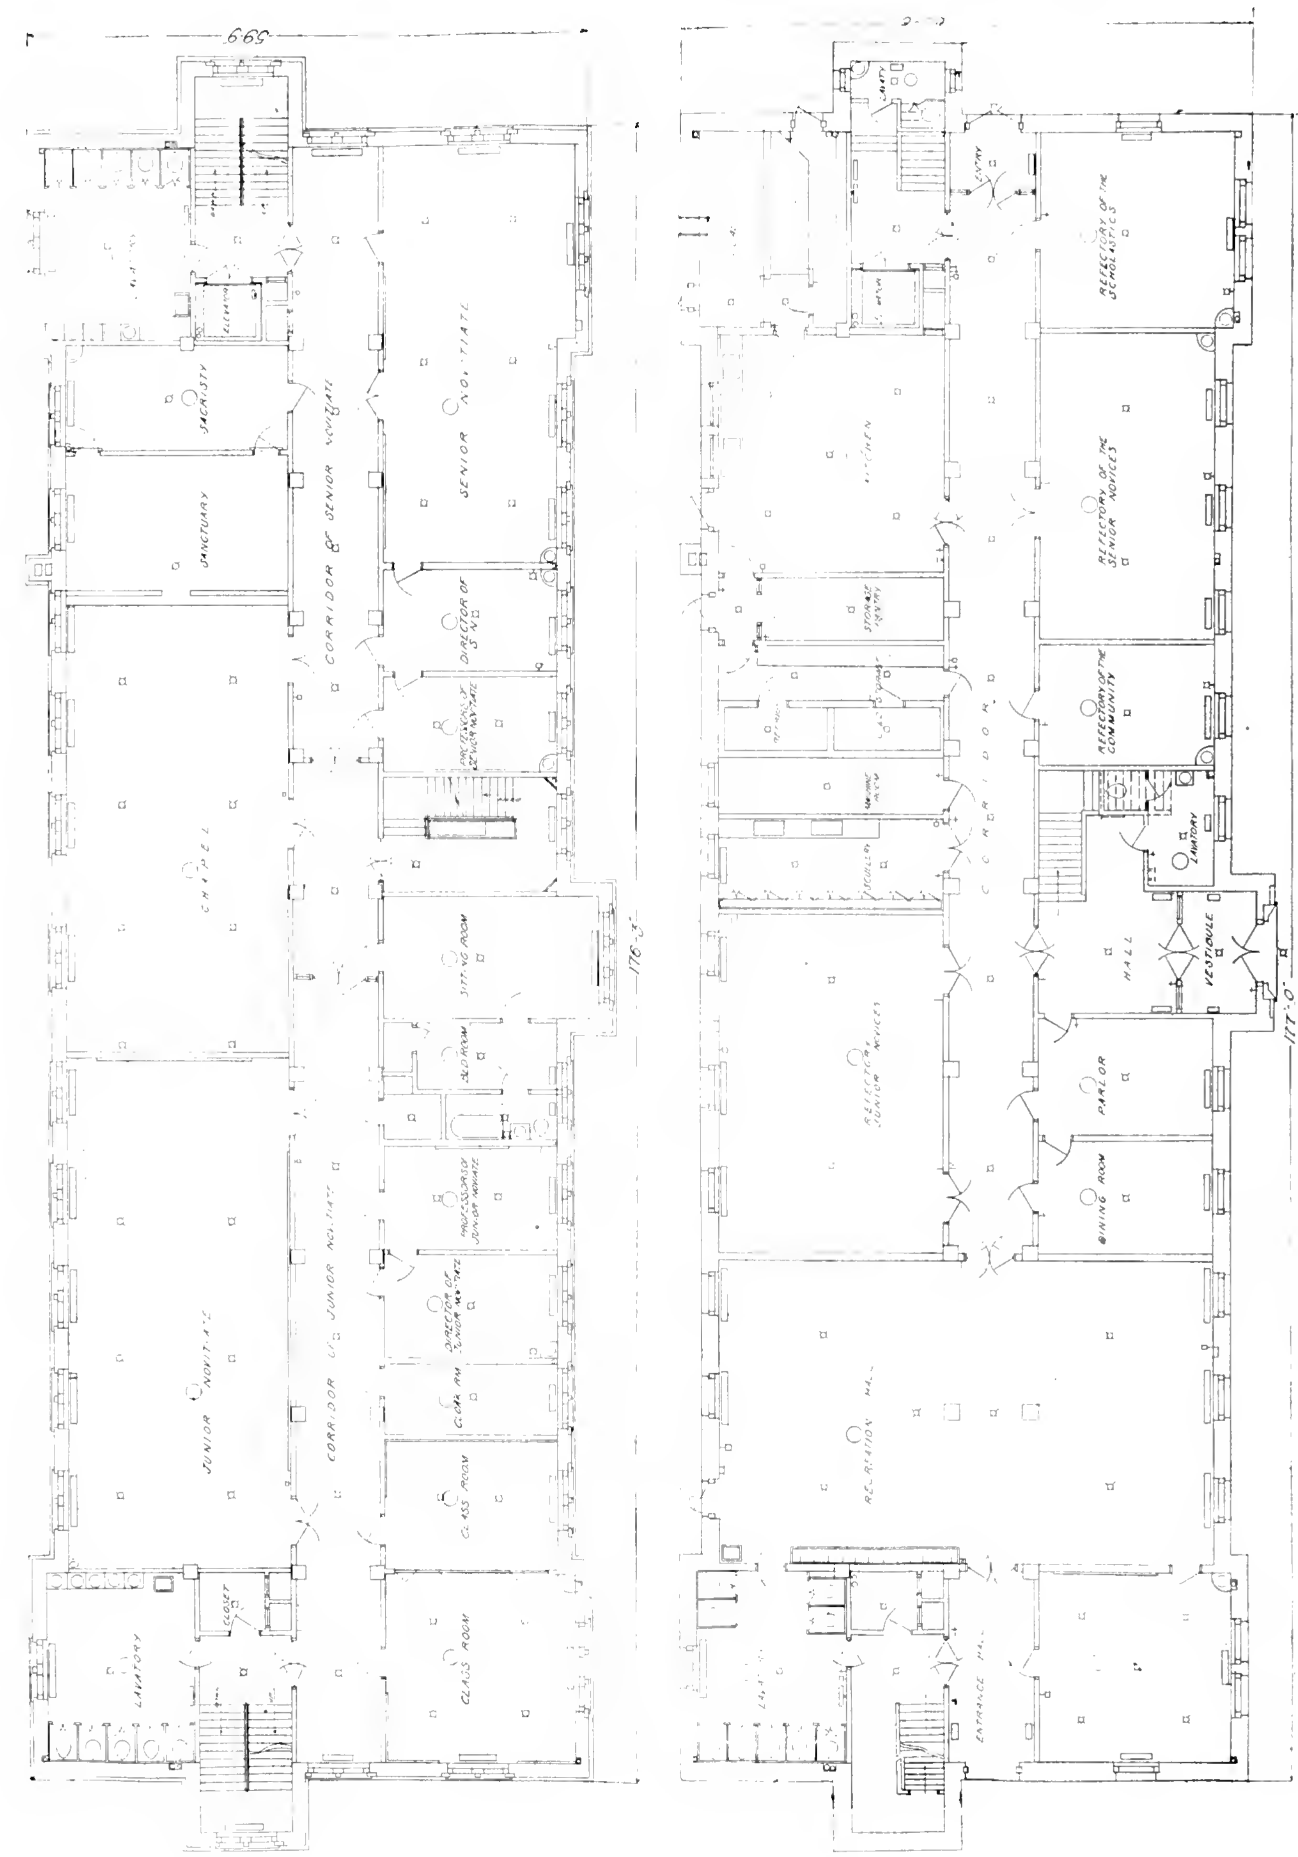
While the water is still too high for a verification of the cause of the accident, it is probable that the failure of the Canadian Pacific Railway's concrete dam at Moose Jaw, which occurred on the morning of April 24, was due to the sliding of the structure upon its foundation. The dam across the Moose Jaw River is of the gravity type, about 300 feet long, divided by buttresses into eighteen sections, nine of which are provided with stop gates. The downstream face had no concrete apron but was protected by stone riprap. The stop logs were all removed at the time of failure.

It is believed that the dam did not break but slid forward about 15 feet on its foundation, due to the washing away of the riprap protection. It is not possible, at this writing, to verify this conclusion. According to old residents in Moose Jaw this year's spring run-off has been equalled only once during the past thirty years, in 1905. In both years of high water the low lying and built-up portions of the city were flooded about 2 feet deep.

Annual Convention of the Royal Architectural Institute of Canada

The General Annual Assembly of the Royal Architectural Institute of Canada will be held at Quebec, Que., on Saturday, 9th September, 1916. All the Canadian architects will be invited and a record attendance is expected. J. H. G. Russell, Winnipeg, Man., President. Alcide Chausse, 5 Beaver Hall Square, Montreal, Que., Hon. Secretary.

The City of Verdun, P. Q., has decided to construct a system of underground conduits, provided a bond issue of $200,000 can be arranged.



Ground (below) and First Floor (above) Plans of the De La Salle Training School, Oak Ridges, Ont.

Hynes, Feldman and Watson, Architects.

De La Salle Training School at Oak Ridges, Ont., Officially Opened

The accompanying illustrations show the prospective and plans of the De La Salle training school at Oak Ridges, Ont., which has just been completed, and was officially opened on May 10. Early in March, 1914, the Roman Catholic denomination purchased 115 acres of land about two miles south-east of Aurora, Ont., as a building site for a training school for the Brethern of the Christian Schools, a school in which male teachers of the separate and other Roman Catholic schools of Ontario should be trained. Plans were prepared and work commenced in October of that year.

The building is approximately 180 ft. x 60 ft., and is of fireproof construction throughout. The walls are Denison interlocking tile faced with common red stock brick with artificial stone copings and trimmings. Foundations and footings are concrete, reinforced with ¾-in. reinforcing bars and dowels. The stone used for mullions and transoms in all windows is artificial stone and the mullions and transoms are filled with solid metal sash, double glazed.

The building contains class rooms, professors' rooms, science rooms and other necessary scholastic departments, and in addition a recreation room, reading room, dormitories, dining room, kitchen, etc. On the ground floor, besides the vestibule, halls and corridors, is a large recreation hall approximately 38 ft. x 56 ft., a parlor, a dining room, refectories for community, scholastics, senior novices and junior novices, a kitchen, pantry, storage room, machine room and coal room.

On the second floor are the class rooms, senior and junior novitiate, with rooms for the directors and professors. A temporary chapel, approximately 50 ft. x 30 ft., with accommodation for 200 people, has been fitted up on this floor. It is the intention ultimately to have a separate building for the chapel. The upper floors are given over to dormitories, bedrooms, infirmary, bath and wash rooms. There are on all floors lavatories at each end of the building.

The building has been made almost entirely fireproof by the elimination of all hardwood floors. Linoleum has been laid directly on the concrete floors and this idea has been carried out even on the stairs. All hall or corridor doors are of fireproof construction. The roof is flat, laid with red promenade tile, and may be used for recreation purposes. There are flights of stairs at each end and in the centre of the main corridor which runs the length of the building on each floor. There is also an elevator, a dumb waiter and linen and dust chutes, to facilitate the work of the attendants.

A brick and concrete power building is built 100 feet north of the main structure and contains the heating boilers, water reservoir tanks, pumps, etc. Heat, light, and hot and cold water are supplied from here to the main building. Electric power, purchased from the Toronto & York Radial Railway Company, is transformed in this building.

The school cost $160,000, and was designed by Hynes, Feldman & Watson, architects, Toronto. Sub-contractors who supplied material and did the erection work were as follows: concrete masonry, Thomson Bros.; carpentry, Geo. L. Robinson; plumbing and heating, W. J. McGuire; plastering, A. D. Grant; painting, Cheshire & Hulme; steel sash, Trussed Concrete Steel Co.; kitchen equipment, Geo. Sparrow & Co. and Murray-Kay; linoleum and electric fixtures, Robert Simpson Co.; tiles, Missisquoi-Lautz Corporation, Limited; wire, A. R. Rice & Co.; ice machine, the Canadian Ice Machine Co., Ltd.

De La Salle Training School, Oak Ridges, Ont.—Hynes, Feldman and Watson, Architects.

A Unique Reinforced Concrete Trestle

A 3¼ Mile Concrete Highway Built with Pre-cast Piles and Floor Slabs—Methods Used in Erection and Transportation

The longest concrete highway trestle ever built is probably that which the State Highway Commission of California have completed over the Yolo by-pass near Sacramento. The highway was officially opened for service a few days ago. The trestle is over three miles long, 20 ft. high, with a roadway 21 ft. in clear width. It is built with pre-cast concrete piles, and the floor is made up of four separate rows of pre-cast slabs placed side by side and spanning the space from bent to bent. There are 2,940 piles and 3,665 slabs used in the construction of the trestle. The method of pile driving, transportation and erection, were unique. The following details of the construction are condensed from articles written by the engineers for the Engineering News.

Existing Conditions

The California State Highway Commission in constructing the highway across the Sacramento Valley had to plan a road which should not be interrupted at periods of flood, which often last for several weeks. It was necessary therefore that the roadway across the Yolo by-pass should be built above flood level and that it should not obstruct the flow of water down the channel.

It was decided that the best and most economical structure to carry the roadway across this channel was a concrete trestle. At one end, however, the final limits of the by-pass channel were not positively determined, and at that end it was decided to build a wooden structure on creosoted piles, which would cost less and be more readily removed in case of necessity than a concrete structure.

The ground crossed by the trestle is a swamp of uniform character, so that it was possible to drive piles accurately and space the bents uniformly. It was decided that the concrete trestle should be built by driving pre-cast concrete piles, four piles to a bent, molding a concrete cap on the heads of each bent and then placing pre-cast floor slabs on these bents, leaving the parapet of the structure and the wearing surface for traffic as the final steps in construction.

For the manufacturing of these piles and slabs a casting yard was located one-half mile beyond one end of the bridge, the site being the nearest location to the bridge that was protected by a levee from the flood waters of the Yolo flood basin.

Concrete Piles

The concrete piles used are 14 ins. square with chamfered corners. There is a reinforcing rod at each corner and spiral hooping. The lower 5 feet of the pile is tapered. Prior to the driving of the piles, numerous test borings and test piles were put down along the line of the trestle. An attempt was made to have all the concrete piles of such a length that they could be driven to the desired grade and afford a resistance to permit a safe loading of 20 tons each.

Piles of five different lengths were cast, as follows: 32 ft. long, 860; 35 ft. long, 1,084; 40 ft. long, 524; 45 ft. long, 236; 50 ft. long, 220. By using these piles of varying lengths it was possible in nearly cases to drive a pile to the final grade desired and obtain the required resistance. The soil encountered was a mixture of sand and clay, with some adobe on top, and varied considerably in bearing power. The penetration under the final blow in some cases was as much as ½ in.; but in others the last twenty or thirty blows lowered the pile only an inch, and in a very few cases it was necessary to cut off the piles.

Reinforced concrete highway trestle 3¼ miles long over Yolo By-Pass, California.

The piledriver was 60 ft. high and was operated by a 8¼ in. x 10 in. hoisting engine with an auxiliary 35 h.p. boiler to supply sufficient steam to the hammer for hard driving. A Vulcan steam hammer was used for driving. This machine had a 3½ ft. drop and 5,000 lb. ram, equipped with cast steel follower. The hammer and follower weighed 5,500 lbs. To carry the piledriver over the soft swamp during the dry weather, 12 x 12 x 24 in. skids were laid directly on the ground with 2 in. x 6 in. greased skidways for the piledriver to slide on. During flood conditions, however, the method was different. A temporary wood trestle to carry the piledriver was driven ahead of the concrete trestle by a small piledriver. The larger piledriver moved backwards after driving a concrete bent and pulled the temporary trestle.

Cushioning the Hammer Blow on the Pile

There were four ⅞-in. reinforcing rods in each concrete pile, and they were left projecting 20 inches above the head when the pile was cast, to make a proper bond

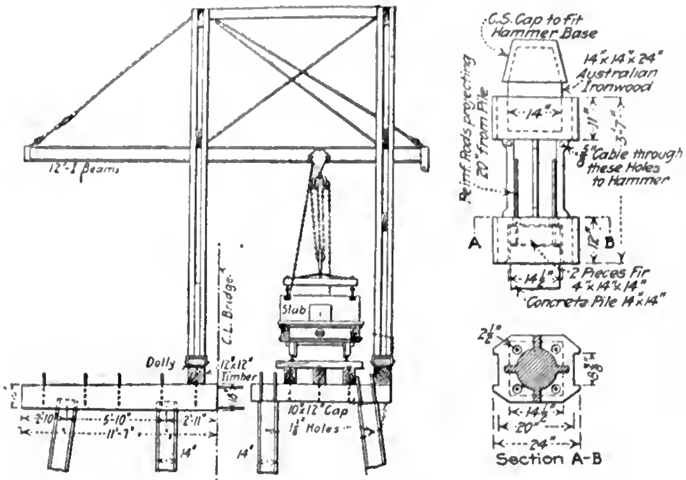


Fig. 2.—Gantry for placing slabs and cap for driving piles.

with the concrete caps, which were later cast in place. These projecting rods necessitated special arrangements in driving the piles to avoid bending the rods. Immediately on top of the piles was placed a 4-in. fir block, or in case of the long piles two blocks, through which holes had been bored for the projecting rods. On top of this wooden block was placed a structural-steel head with a sliding cast block. Later a cast-steel head was used, holes being cored through it to admit the rods. On top of this cast-steel follower was placed a 14 x 14-in. block of Australian ironwood, to receive the blow of the hammer. This block, chamfered at the upper end and fitted with a cast-steel cap, shattered rapidly under the shock of the hammer, lasting from one to five days, or a maximum of about 100 piles driven.

Erection of Trestle

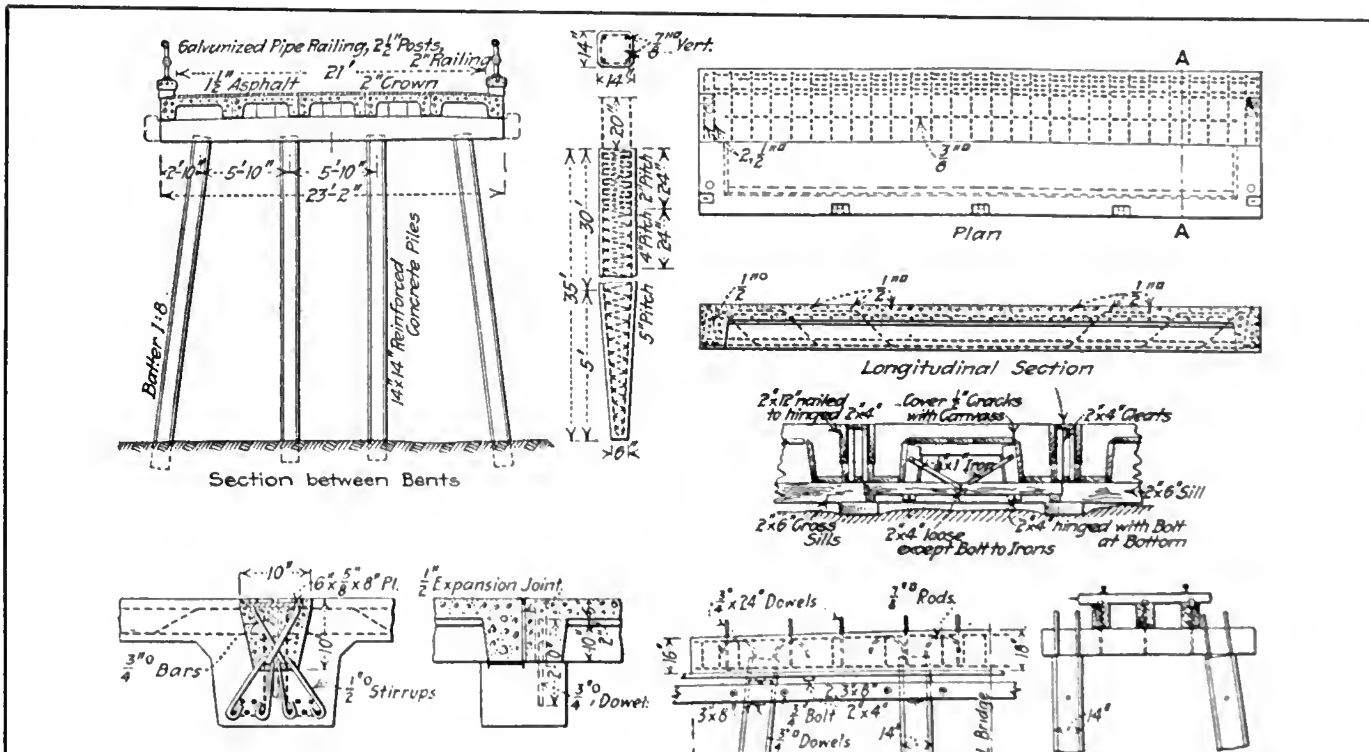
Each bent has four piles, the interior two being vertical and the outside piles having a batter of 1 to 8. As soon as the bent was driven a temporary deck was placed on the two south piles. The deck consisting of a 10 in. x 12 in. cap on which were placed stringers spanning the 20 ft. space from bent to bent, and on the stringers were laid cross ties and an 18 lb. rail for 3 ft. gauge tracks. The next operation was the casting of the reinforced concrete cap on the north half of the pile bent. Wood forms were built around the heads of the piles and the caps poured and allowed to season thirty days. The floor slabs for the north half were then brought from the casting yard, set in place on the caps and grouted. The temporary track was then removed from the south side of the bent to the north half and the south half finished in a similar manner.

Floor Slabs

As may be seen from the accompanying drawings, each floor slab has the general form of an inverted box. The floor is 6 inches in thickness, with projecting flanges of a total depth of 18 inches. Great pains were taken in the design of the slabs and caps, so that the completed trestle is a monolithic structure, although the separate parts are assembled as pre-cast units. Rods were left projecting from the top of the trestle caps, and 3-in. holes were bored in the floor slabs, so that as the floor slabs were set they dropped over these rods. The holes were later filled with grout. At every third bent of the trestle was placed an expansion joint.

For hauling the piles, slabs and other material from the casting yard to the end of the trestle, special cars were used, consisting of two sets of car trucks connected with a reach, and two 12 x 12-in. timbers set on top of the trucks. Two floor slabs made a load for one of these cars, and a train of three loaded cars was pulled by a gasoline locomotive.

For setting the slabs on the trestle cap a gantry crane traveller was used carrying two 5-ton chain



Details of trestle construction, Yolo By-Pass, California.

blocks. When used to set the first row of slabs on the north side of the trestle, the traveller ran on 12 x 12-in. stringers which on one side rested on the inner end of the concrete cap and on the other side rested on the outer side of the cap on the temporary construction track, as shown. To prevent the traveller from tipping, it was chained down when setting the first slab. After this slab was placed, however, a plank was laid on top of it, and then a traveller was used spanning the entire trestle. With these travellers it was possible to set the floor slabs very carefully and accurately. Accuracy in setting was essential, as the bottom edges of the longitudinal joints had to be flush in order to grout these joints. Accuracy in placing the slabs was essential also, on account of the method of fastening used.

In casting the outside slabs for the floor a row of 1½-inch holes 6 inches deep was cored in the slabs. After the slabs had been set, rods 12 inches long were inserted in these holes and grouted in place. These projecting dowels hold the parapet in place on the floor. The parapet is of simple form, 15 inches in height with arch openings. Besides acting as a curb, it supports a galvanized-pipe railing, the top of which is 43 inches above the floor. The wearing surface of the roadway is a layer of asphalt 1½ in. thick. The roadway has a 2-inch crown at the centre, this crown being formed by casting the trestle caps 2 inches higher at the centre than at the sides.

The unit system of construction adopted in building the trestle, not only produced a permanent structure built of uniformly high quality material at low cost, but enabled the work to be prosecuted very rapidly.

A short span bascule bridge has been provided, crossing the navigable channel at the east end. In building the trestle the following amount of material was used: 21,692 tons of crushed stone, 12,553 tons of sand, 32,000 barrels of cement, 8,200 tons of reinforcing steel. These material cost in the neighborhood of $148,000, and the total cost of the trestle was about $395,000.

The Use of Fir Blocks in Pavements

A Committee of Engineers, After Extensive Investigations Decide on Wood Block Paving in Preference to Other Types

A committee of expert engineers, appointed by the municipal legislature of Seattle, after four months of investigation, tests and experiments, recently submitted their report, in which they recommended creosoted Douglas Fir wood block paving on the big East Marginal Way improvement. The engineers spent weeks in actual, physical examinations of different types of street paving, which covered many miles of highways, securing many samples for test figures. In their report they recommended to property owners wood block paving as the best investment. The following is extracted from their report:—

Types Adaptable

"The character of pavements best suited to this class of traffic in this location—practically a water grade—are concrete, brick and creosoted wood block. As it is customary that all paving work done within the city limits should be done under the supervision of, and upon plans and specifications drawn by the city engineer, the county commissioners arranged with the city engineer's department to do this work in the regular way and specified brick paving on a strip twenty feet in width representing 39,000 square yards of paving. This was objected to by the wood block interests on the grounds that a certain percentage of the abutting property owners preferred wood block and that it was an equally suitable surfacing for the improvement. The details of what developed into an acrimonious controversy between commissioners, property owners and paving interests have no bearing on this report, except that it resulted in assurances from the county commissioners that brick block and wood block, and only these materials—would be taken into consideration and the indefinite postponement of their decision. For this reason only these two surfacings have been considered in this investigation.

"In preparing the following table for this improvement showing the comparative values of surfacing, the percentages have been arrived at by using the paving reports of the U. S. Forest Service as a base and making independent investigations to suit the particular conditions and location under which this improvement is to be laid and its probable future duty. The costs include labor and material of surfacing and 6-inch concrete base.

Comparative Values of Surfacing

Qualities	Per cent.	Brick	Creosoted Wood Block
1. First Cost	25	13.0	13.0
2. Maintenance (in which is included annual cost*)	25	18.4	20.6
3. Low Taction Resistance	15	13.4	15.0
4. Slipperyness	10	7.9	5.7
5. Sanitation	10	8.5	8.6
6. Facility for Cleaning	10	9.0	9.5
7. Freedom from Dust, Mud, etc.	5	3.4	4.7
Total number of Points	100	73.6	77.1

	Brick	Creosoted Wood Block
Average cost per Sq. Yd. Laid in Seattle in 1912-14	2.60	2.65
Average cost per Sq. Yd. Laid in Seattle in 1915	2.51	2.45

"In all comparisons city of Seattle standard brick block 4⅛ in. x 3⅜ in. x 3¼ in. with a three per cent. absorption test and Douglas fir block 3¾ in. x 3½ in. x 6 in. to 10 in. with 16 lbs. of creosote per cu. ft. reduced to 12 lb. by vacuum treatment have been used.

First Cost Figures

"The figures for first cost are contract price figures of the city of Seattle and it will be noted that during the last two years there has been a decided equaliza-

* Annual Cost—Interest on first cost plus maintenance cost plus annuity.

tion of the price, the average of the two averages given being practically identical.

"There has, however, been an item properly chargeable to first cost that, as far as your committee has been able to determine has not been charged to the brick cost. This is the cost of sand and planking laid over a new brick pavement in order to avoid its being closed to traffic for from thirty to sixty days and runs in the neighborhood of thirty cents per yard. This charge has not been taken into consideration in the previous schedule of percentages as being pertinent to this particular improvement. The sand sprinkled upon the completed surface of a wood block pavement upon its completion costs about one cent per yard and the wood block is ready for traffic forty-eight hours after completion.

"It must be borne in mind through all these comparisons that the cost of brick block in the East and Central West averages from $16.00 to $18.00 per M., while the same brick at Seattle costs $30.50 per M. and that the treated longleaf yellow pine which is almost exclusively used in the East and South for paving, costs more in those districts than does the treated Douglas fir in Seattle. This makes the first cost of material for surfacing brick pavements in other parts of the country a little less than one-half of the cost here while the cost of wood block is correspondingly higher; a general average for finished pavement being $2.05 per sq. yd. for brick and $3.00 for wood making the ratio two to three for the completed pavement.

Maintenance Charges

"The figures on brick pavement compiled from city data give a maintenance cost of .0299 cents per sq. yd., for something over 1,000,000 sq. yds.; an annual charge of about $30,000.00.

"Figures from the maintenance department of the local street car company for the year 1913 give the cost of maintenance of their portion of the brick paving between Pike and Yesler Way on Second Avenue as $0.435 per yard.

"The records of eighteen other cities in the United States given by city engineers, highway commissioners, etc., shows a decided preference for wood block and a much lower maintenance cost than for brick.

"Your committee can find no facts or figures to substantiate the claim that longleaf yellow pine or other woods are superior to Douglas fir for the purpose under discussion. Records of failure of Douglas fir that your committee have investigated lead to the conclusion that such failures were due to improper treatment or laying, more frequently the latter. Records of failure of brick block as a pavement have shown they have been principally due to the failure of the material itself though in some cass to faulty construction.

"Comparative measurements of the two materials for the same period of use under the same approximate condition show a greater loss of bulk in brick.

"We find practically no difference in the resistance to traffic and slipperyness in the two materials when laid on water grades and with practically no curves in alignment as is the case on East Marginal Way.

"Because of the location and character of the improvement the relative merits of the surfacing of the two materials when compared as to sanitation, facility for cleaning, and freedom from dust, mud, etc., would be about equal with possibly a slight percentage in favor of wood block.

"In summing up the more important considerations which should receive attention in any selection, your committee is in accord with the report published in the December proceedings of the American Society of Civil Engineers, namely, 'That for brick, toughness, resistance to wear from shock or abrasion, and non-absorption are essential qualities. That uniformity of wear is equally important, and may properly be a controlling consideration even at the expense of a moderate sacrifice in the rate of wear. That cement joints when properly made will maintain the integrity of the pavement but uniformity in the cement grout and special skill and care in its application are essential to success. That a sand cushion is necessary only to allow for irregularities in thickness of brick and surface of concrete base and should be limited to one inch or even one-half inch.' From our observations and inspections we find that the brick used in Seattle has apparently deteriorated in quality in recent years along the following lines:—toughness, resistance to wear and non-absorption. We understand that the city testing laboratory discovered some reasons for this deterioration and that the brick block manufacturers have done their best in co-operation to overcome the trouble. However, the new product must be subjected to actual traffic conditions for some years before a more favorable report than is now possible, can be rendered. The city of Seattle specifications call for three per cent. maximum absorption which will in all probability be specified for the East Marginal Way improvement. One and one-half per cent. maximum absorption, in the opinion of your committee, is the proper amount allowable and the amount generally insisted upon in other cities on pavements that will at any time have a heavy taffic duty and the amount which was required for the brick in the recent paving of Second avenue. We have not found that this letting down of the bars has improved the quality and uniformity of wear is not apparent on several of the pavements laid within the past five years.

Fir vs. Pine Blocks

"Continuing to quote from the above mentioned report 'There is no general necessity for confining the material for wood paving blocks to longleaf Georgia or yellow pine, that no necessity exists in the case of wood block pavement, for a resilient cushion, under the blocks, and the reduction in any such cushion, to a layer as may be necessary, safely for the purpose of correcting the unevenness of the foundation and of permitting the immediate compensation for irregularities in the depths of the blocks themselves. That this layer should be of such character as to insure its permanence in the position it occupies when the pavement is opened to traffic. That an excessive quantity of preservative involves additional cost without compensating advantages while if too little is used it may fail of its purpose.'

"We have found in Seattle that irregularities in surface of wood block pavement is due almost without exception to the shifting of an excessively thick sand cushion or to the disintegration of blocks having too light a treatment of preservative.

"To re-capitulate, we have a concrete base, common to either pavement, but above this in the case of the brick there is a cushion of sufficient thickness of more or less unstable material to make its retention in its original place a serious problem. And on this cushion is a wearing surface of material which has not proved uniform and has proved comparatively expensive to maintain. In the other case, on a concrete base we have a cushion so thin and of such a plastic nature as to be easily controlled and a finished wearing surface which has proved uniform in quality and for which the maintenance is exceptionally small.

"Judging from the more recent bids under present Seattle specifications, we believe the difference in cost as between brick and wood will be small. Furthermore, we believe that with changes in the specifications—to secure materials of recognized equality of their respective kinds, the cost will be appreciably less with wood than with brick.

Recommend Wood Block

"From all the foregoing, your committee respectfully recommends the use of creosoted wood block pavement for the improvement of East Marginal Way, and further that the specifications governing same be revised in accordance with the most modern and up-to-date methods and practices.

"Before closing this report your committee feels it their duty to suggest for your earnest consideration, the following: Since for some years East Marginal Way will not, in all probability, be much travelled, since the traffic is not likely to be heavy concentrated loads, and since what ever saving possible should be made to the taxpayers and abutting property owners, we believe it to be to the best interests of those most vitally concerned to install at this time the concrete base, using a surface hardener to take the wear. Such a pavement can be guaranteed to last for at least five years and will obviate the expenditure of many thousands of dollars till such time as the traffic warrants such expense.

"For instance, the cost of the concrete base will be the same in any case; to this add twenty-two and one-half cents per square yard for surface hardener and when the proper time arrives to put on wood blocks, it may be done with no delay and little or no inconvenience to whatever traffic exists. The cost of cushion and wood blocks at present prices is about $1.60 per square yard. If this amount was invested to draw only four per cent. interest, the interest would amount to $0.32 per square yard in five years, or more than the cost of hardener, and with a guarantee the maintenance would be nil.

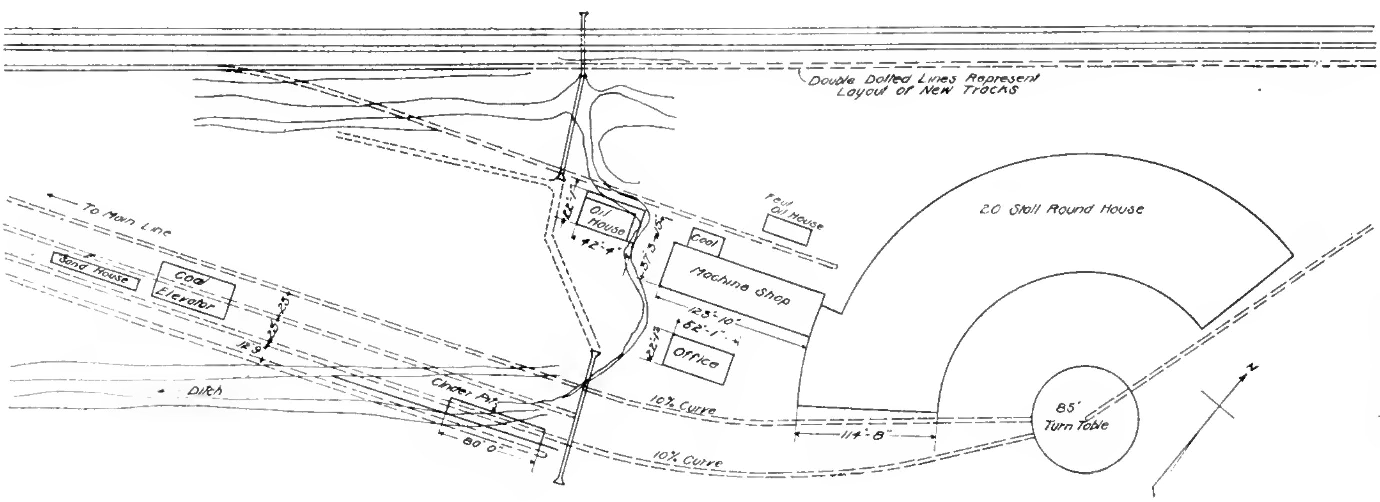
"If at the end of five years traffic it does not seem to warrant the expense of blocks, taxes and assessments will be correspondingly kept down.

Estimates

"In other words your committee estimates that for 39,000 square yards all expenses up to and including the concrete base will be constant for any pavement. For hard wearing surface on concrete, add $8,775.00, for wood blocks, $62,400.00, the difference of which is a saving of $53,625.00. This sum invested for five years at four per cent. will amount to $64,350.00, as against $62,400.00, estimated to be required. Or figured another way, property owners and taxpayers can be relieved of the interest on $53,625.00 for a period of five years or more, for a road surfacing which in the estimation of your committee is at present an unnecessary expense. These figures are based on the length of East Marginal Way as specified in the original bond issue and not upon its length after connection with Duwamish avenue."

M. C. Railway Terminal at Montrose, Ont.

THE cut herewith shows the proposed layout of the new railway terminal to be built by the Michigan Central Railway Company at Montrose, Welland County, Ontario, this year. The layout includes a roundhouse, machine shop, office building, coaling station, sand house, oil houses, and cinder pit, besides the necessary new tracks. The roundhouse, which has accommodation for 20 locomotives, is to be brick and mill work construction; the plan is an arc of a circle of 140 degrees on a 120 ft. radius circle, inside diameter, 217 ft. 8 in., outside diameter, that is, the width, is 97 ft. 8 in., which enlarges to 114 ft. 8 in. where it connects with the machine shop. There is an 85-ft. turntable in front of the roundhouse connected with three outgoing tracks to the main line. The machine shop, which is connected directly to the roundhouse, is 123 ft. 10 in. x 37 ft. 3 in., and together with the office building, which is situated in front directly south of it, will be built of brick. The oil houses will be of reinforced concrete fireproof construction. The terminal is expected to be completed by the fall.



Proposed layout of the M. C. R.'s New Terminal at Montrose, Ont.

The Adaptability of Paving Materials

To Different Conditions and Localities—A Good Opportunity for Utilization of Local Materials

By F. C. Pillsbury*

The adaptability of road paving materials to different conditions and localities when thoroughly considered embraces a very wide field. The subject, if taken literally, does not permit limitations, and I assume it is desired to be as comprehensive as possible. It should be borne in mind that few, even of the highest authorities, have had actual and thorough personal practice and experience except within more or less limited territory, and on this account it is well to emphasize that the practice which might be excellent in one locality would fail at some other place.

The pavement or surface of the road, to be thorough in the consideration of this subject, must be considered as the whole of that portion of the road which is, artificial or natural as the case may be, to its full depth, serving the purpose of carrying the traffic. It is not safe to attempt to decide upon the selection of any wearing surface without giving due consideration to those parts lying immediately beneath, and which are generally termed, (1), the base or bottom course, and (2), the subbase or foundation, also to the nature of the ground upon which the whole is to rest.

The selection of pavements and road surfaces is a subject which has been fully and ably covered a number of times, so there is little to add that will be of interest unless it is taken up from a different point of view, which may be done by considering in an elementary way some of the rudiments and their general applications, under different conditions and in different localities. These conditions may be classified under the following two headings which seem to represent the predominant factors—climate, including its principal conditions of temperature and moisture, and traffic.

Climatic Conditions

The climatic conditions at all times affect all kinds of surfaces. The effects are exceedingly various and not due to, nor are they to be measured by, the changes in temperature or moisture alone, but also according to the traffic and the nature and qualities of the kinds of materials used. A high temperature has a tendency to soften bituminous materials; a low temperature to make them brittle, with a tendency to break. Moisture becomes absorbed, thus causing expansion, while high temperatures as well as extremely low temperatures increase this result, and medium low temperatures generally cause contraction. In some materials these physical changes become very serious, frequently causing destruction when not taken into account. The chemical conditions following the changes of climate are usually so indefinite and of such slight consequence that they need seldom be taken into consideration. Materials should be of such nature as to carry the traffic with the minimum effect of these climatic changes. Some surfaces would be satisfactory in certain climates and would fail in others. Certain materials might be used in one climate and would fail utterly under similar conditions in another climate, while the same type of pavement made of exactly the same material to answer similar requirements would be successful if constructed by different designs, taking into account the effect of the climate. For instance, the thickness of certain types of pavement should be much greater when subject to frost than in climates where there is practically no freezing.

The necessity of providing for the requirements of traffic is imperative and the materials which will sustain traffic in a hot climate may not answer in a cold climate, and vice versa, although certain materials may be manufactured and so used that the changes of climate will have very little effect upon them. These include stone block, wood block, brick, broken stone, and other minerals of more or less solid nature as well as some bitumens, these latter, however, acting like Portland cement as cement or binder. Portland cement concrete is apt to break up from expansion and contraction following extremes of wet and dry or heat and cold. Asphalts and bitumens should have a very low penetration, that is, be quite well solidified when used as a cement or binder in warm climates, otherwise they become softened under a high degree of temperature. This is always to be considered, to a certain extent, in any climate. Bitumens should never be of such a nature or quality as to become brittle when cold. Certain asphalts are less likely to be affected this way by low temperature than others, and probably nearly all of them might be prepared so as to retain the necessary degree of plasticity when cold, at the same time having sufficient stiffness when subject to a high temperature. Certain proprietary and patented compositions, consisting mainly of matter with which it is necessary to use bitumen, are as little affected by changes in temperature as the very best asphalts, but on the other hand they are probably readily affected by moisture.

Other Requisites

While there are certain other requisites such as those related to hygiene and aesthetics, these are not usually necessary requisites, inasmuch as they do not have to be provided for in determining the choice of materials, except as secondary considerations. Nearly all first class pavements and road surfaces can be easily made sanitary, practically dustless, and reasonably free from mud, and will remain so if properly designed and cared for, considering traffic and natural conditions only. Aesthetic requirements are related usually to park systems and private roads, although they should not be forgotten in connection with public highways. They are almost always satisfied by the results obtained from an excellent surface and the surroundings of the road, such as tree planting, roadsides, etc. Noise, however, depends directly upon the kind of traffic and cannot always be easily overcome. There is little excuse for the very rough and uneven stone pavements which exist in many of our cities. Stone pavements can be so constructed and maintained as not to be seriously noisy, and the tendency is toward smoother pavements. Noise is a serious consideration in cities and should always be avoided so far as possible, but in these days of mechanical vehicles there seems to be more of an opportunity to overcome noise in the vehicle itself due to the condition of the vehicle rather than the condition of the street. There is an-

* Division Engineer Massachusetts Highway Commission, before the American Good Roads Congress.

other condition, but this is related more directly to traffic, and that is non-slipperiness for horses. While this is also a secondary consideration except in extreme cases and on steep grades, it should ever be kept in mind and both design and materials be provided to reduce the slipperiness to a minimum. It can be overcome to some extent by the reduction of grades and flattening of cross sections, also banking curves. The entire elimination of slipperiness cannot be accomplished without extraordinary cost, except on those roads subject to very light traffic or in warm climates. It would seem unreasonable to attempt to overcome, in the design or choice of material, the occasional slipperiness due to icing of the surface. It is possible by sanding and frequent cleaning, when the grades and cross sections are suitable to reduce the slipperiness to a reasonable state. It would be possible to construct bituminous pavements with surfaces so rough that they would not be slippery, but such surfaces, on account of their roughness, would be subject to those forces which naturally result in wear and would lead to abnormally rapid destruction.

There are so many known materials adapted for use in paving road surfaces that they are almost numberless. If this be true of those materials that are known, how many must there be that are unknown! This vastness in variety, however, seldom applies to a selection in any given locality. Usually the problem is not an extremely difficult one for an experienced engineer provided he is not limited unreasonably by the local demand, financially, or in other ways. The writer has observed that the highway laws in the United States are generally so imperfect and the highway organizations of the various communities in the states so irregular and incomplete, that many times wisdom is not displayed in the selection of types of pavement and materials with other matters relating to the same. The development of this whole question has been so rapid and it is continuing to develop so extensively that the general public as well as many of those actually engaged in the work have failed to realize the changes that are demanded in almost every way. This condition is not surprising, but is to be expected. Much can and should be done to increase the knowledge of those upon whom the work will fall, as well as the general public.

In the question of the selection of materials, as far as they are influenced by these main considerations, it matters little, as to the quality of material or actual design of the pavement, whether the location is in the country or in the city. These variations in location should be subject to the same methods of treatment, in providing for the effects of traffic and climate, all other requisites, of course, being taken into due consideration.

It is a coincidence worth remarking that road pavements are with few exceptions composed of materials taken directly from the earth, usually without great change in composition, and used for a purpose that requires their being placed back again on the earth, and hence to a degree are subject to the effects of the same natural forces as before their removal from the earth. When exposed to the weather, as road surfaces are exposed, the effects of natural phenomena on these materials are greatest. It has been said, and truly, I believe, that the wear of a road surface might be one half due to the effects of weather and one half due to traffic. The weather, through which climate is mainly evident, is working all the time, and almost always for the deterioration of the road surface. This is not always given due consideration. Having in mind as far as practicable all these requisites and conditions, the writer gives the following list of natural materials, together with some of their common uses, but he believes the competent road designer should be able to go still further and invent—if that word is not an improper one to use in this connection—new combinations or methods which it will often be found advantageous to adopt.

It is not practicable to enumerate here all the different materials, but almost all, and enough for the purposes of this paper, are included in the following:

Natural Materials

Loam, by which is meant that fertile covering of most portions of the earth, composed principally of clay, fine particles of sand, and vegetable matter; sand including all so-called sands, from the finest to those in which there are no particles over ¼ in. in size; gravel, meaning masses composed of fragments of rock loosely mixed with more or less sand and sometimes including a small quantity of loam or clay, the particles of rock being either worn smooth and round or of any form to that sharply angular, often more or less coated with clay or marl, but never compacted so closely and firmly in a solid mass as to be confused with bowlder clay or the hardpans; clay, including pure, fine clays, marls, and earth consisting of more or less clay, found in dense and compact masses with fragments of rock of any size, including bowlder clay and clay hardpan; stone or rock, meaning all kinds of stone materials, not including those minerals classified as sand, gravel, clay, etc., and any ledges, boulders or stones when separate from masses of clay or gravel; bitumens, including asphalts, oils and tars; wood; and shells.

At the present time these natural materials are used in many ways and in innumerable combinations. There is unlimited opportunity for development in use and composition, even to the extet of the discovery of some method or material or combinations of the same absolutely new, and perhaps possessing certain qualities that would accomplish more of the results required than any material in existence at present.

The more common uses of these materials are so well known that it is unwise to include many of them in a paper of this kind, but it may not be uninteresting to discuss those cases which are connected with conditions which should govern the selection and which are sometimes in dispute or not generally known or perhaps not recognized as being of importance. This the writer will endeavor to do, taking up the subjects in terms of the natural materials and others, as already defined, and considering not only their fitness, but dangers to be avoided when improperly used or allowed to remain in risky positions.

Loam or loamy material is seldom of value, particularly in climates subject to much moisture or cold. In these climates, however, it is sometimes used as a binder under certain conditions with sand, gravel or broken stone and with bituminous mixtures. Even this use is to be avoided when the cost of other materials which would answer the purpose is not prohibitive, because the value of the loam lies alone in the fineness of its particles, which enables it to act as a filler. It is so quickly acted upon by moisture, frost, wind, etc., that it has practically no stability. In climates subject to frost action, except where it is very slight, loam should be eliminated as much as possible from use in the pavement material and should not be allowed to remain in its natural position in the roadbed within less than 12 ins. of the bottom of the base unless the road is to be subject to very light traffic, because its instability and tendency to decompose cause the surfacing above to become driven out of place and broken up. A macadam, either water bound or bituminous, is more disastrously affected in this way than gravel, as the gravel surface is somewhat loose and is not ruined even if it does go out of place, whereas the crust-like formation of macadam or bituminous surfaces is liable to breaking and to greater difficulty in restoring afterward.

Loamy materials readily absorb, and generally after absorption retain for a long time, moisture which when present in great quantity leads to tremendous expansion on freezing. This becomes a very destructive condition, under any pavement, and if it is not possible or expedient to avoid placing the pavement on or too near the loam, every possible means should be taken to keep the water out of it.

Work Started on the Extensive Winnipeg Building Program of the T. Eaton Co.

On March 3, the T. Eaton Co. Limited, of Toronto and Winnipeg, submitted to the Winnipeg city council for approval, plans and specifications for a mammoth twelve storey building, and extensions and improvements to the existing premises. The plans were referred to a joint committee of the Water Works and Fire, Water and Light committees, since the permit would have to be a special one, due to the fact that the building could not conform to the present building bylaw of the City of Winnipeg, which states that no building shall be higher than 108 ft., whereas the plans for the new building call for a height of 215 ft.

This excessive height for a twelve storey building is due to the fact that the owners insisted upon special attention being paid to the matter of ventilation. From floor to ceiling, the basement is 18 ft.; ground floor, 20 ft., which is equal to two storeys in an ordinary office building; the second and third floor, 18 ft.; the next five, 17 ft.; and the balance 16 ft. There were a few other minor details which were not in conformity with the building by-law, but the plans were passed by the special committee of the Winnipeg city council. Speaking on behalf of the Timothy Eaton Co., Mr. McGee assured the council that, not only would the premises when completed be a credit to Winnipeg, but the firm had undertaken to do everything possible to make the store the finest on the American continent.

The scheme comprises a series of connected structures, twelve storeys in height, replacing the present nine storey building. When complete it will take in the whole area of the city block, between Graham Ave., St. Marys Ave., Donald and Hargrave Streets. Two bridges, 3 ft. from the ground and nine storeys high, and sundry tunnels under streets, will connect the buildings. The bridge across Graham Ave. will be a means of life saving by allowing communication from one building to the other in case of fire. The work is to be done in units with the entire scheme extending over a period of eight or ten years. The whole proposition will involve an expenditure of approximately $6,000,000.00.

The plans and specifications for the building were prepared by Graham & Burnham, architects, Chicago. The building is to be Tyndal stone from the ground to the top of the second storey; the remaining storeys to be of buff face brick. The structures will be fireproof, with stairs and elevators enclosed, sprinkler system, conveyor, and the most modern equipment for department store convenience. Water storage to the extent of 150,000 to 200,000 gallons will always be available, and the pumping facilities will be of the most up to date kind.

The work at present in progress is the erection of the warehouse section. The foundations are designed for twelve storeys, but of these only eight will be built this year. It will have three fireproof stairs, two 12 ton elevators with platforms large enough to accommodate loaded motor trucks, eight freight elevators—7,000 lbs. capacity each, and two elevators for combined freight and passenger service. Spiral chutes will be installed for conveying packages to the main floor and basement, belt conveyances being used for

Architect's perspective of the T. Eaton buildings, Winnipeg, when completed—Cost $6,000,000.

bringing goods over the main store through one of the tunnels. In fact, every modern labor-saving device will be installed.

The contract for the warehouse was let the very day the city council passed the plans, and the next day the contractors were excavating for the foundation work. At present the trenches for the retaining walls on the east and south ends on Graham Ave. and Hargrave Street, are finished, and pouring cement in these sections has commenced. The north and west walls will not be dug until excavation is completed. Basement excavation is about half finished; work on this is very slow, due to the heavy nature of the clay soil; it is expected that it will be finished by June 1. All the reinforced concrete cassions have been completed; these go to bed rock, an average distance of 50 to 60 ft. with a maximum depth of 80 ft.

Progress on the building, which was expected to be rushed by day and night shifts, is being somewhat retarded by the war, and only a day shift is at present employed on the foundation work. The Bethlehem Steel Works, who are rolling the steel, are also engaged in munition work, making delivery of steel somewhat slow. The first of the steel girders is expected early in June, when progress will become more steady and rapid. Some of the grillage has already arrived. Graham Ave. is now closed between Donald and Hargrave streets until the tunnel, on which work is being pushed rapidly, is completed.

The project in its entirety is a vast one, and indicates the confidence of the Timothy Eaton Co. in the future development of the Canadian West. The tendering for the contract was extensive and spirited, several large U. S. and Canadian firms submitting tenders. The general contract of the warehouse was awarded to Carter-Halls-Aldinger, Limited, for $600,000.00, and the Dominion Bridge Co. was awarded the steel work for $200,000.00. There will necessarily have to be considerable quantities of material imported from eastern Canada and the United States, because of the limited list of Manitoba building material, but wherever possible, material will be purchased in Manitoba.

Bed Testing, to Determine Its Supporting Power for Drain Tile and Sewer Pipe

INTERESTING data on the effect of the method of bedding upon the supporting strength of drain tiles and sewer pipe was recently compiled by N. J. Schlick, drainage engineer of the engineering experimental station, Iowa State college. Tests were made on 24 in. pipe with the different types of bedding indicated in the diagram, and were made when the concrete beddings were one month old; only one series of tests were made, and while they cannot be taken as final, they show some very general facts. The following extracts are based on a paper by Mr. Shlick before a recent meeting of the Iowa Drainage Association.

The types of bedding tested might be divided into three general classes, namely, earth beddings, concrete beddings for firm soils and concrete beddings for yielding soils.

The first of the earth beddings, class 1, was made in accordance with the "Ordinary" method described in the "Standard Specifications for Drain Tile" of the American Society for Testing Materials except that the pipe were only bedded to a little above the mid-height. The trench was shaped in the bottom to approximately fit the lower 90 degrees of the pipe and the ditch filling shoveled in without tamping. There was quite a wide range in the supporting strength of these pipe, but the average agreed quite closely with the average strength as shown by standard strength tests with sand bearings. Because of this close agreement the average supporting strength of class 1 is taken as a basis for comparing the strengths developed by the other types of bedding.

The second class of bedding was the "First Class" method described in the standard specifications. The trench bottom was sloped more accurately and was covered with 1 in. to 2 in. of loose top soil before the pipe were laid. The filling was carefully tamped in, especially at the lower ⅛ points, up to a little above the mid height. The average strength of this class was 28 per cent. greater than that of class 1 and there was considerably less variation in the results from the individual specimens.

In the other type of earth bedding, class 9, the pipe were laid in a flat bottomed trench and the spaces between the pipe and the sides of the trench shoveled full of loose earth. No especial care was taken to see that the spaces between the bottom of the trench and the pipe were filled, and examination after the test showed that the filling there was so loose as to give the pipe no support. The average strength of these pipe was 26 per cent. greater than those of class 1. This increase in strength is thought to be due to the frozen condition of the ditch filling material at the sides of the pipe at the time the tests were made. There is reason to believe that this type of bedding will usually give lower strengths than class 1.

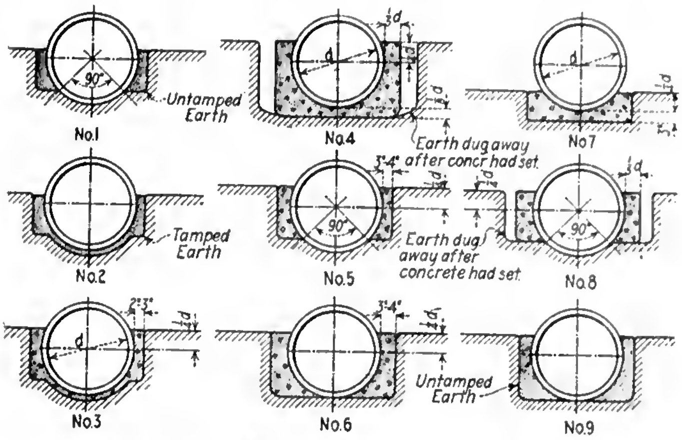
The results of these tests of pipe in earth beddings bring out two especially interesting facts. First: The strength of the pipe laid in the "Ordinary" method agreed very closely with that shown by standard strength tests of similar pipe, and second, that an increase in strength of 25 per cent. can be obtained by more careful bedding, as is specified for "First Class" pipe laying.

None of the pipe in earth beddings would support a larger load than that at which they cracked.

The pipe laid in concrete cradles as specified in the standard specifications for "Concrete Cradles" for "Solid Soils" were tested as class 3. The concrete used was proportioned 1:8. The bottom of the trench was shaped to fit the lower 90 degrees of the pipe and 2 in. of concrete placed on it. The space between the sides of the trench and the pipe, about 2½ in. at the mid-height of the pipe, was then spaded full of concrete up to a height of one-fourth the nominal diameter of the pipe above the mid-height. These pipe had an average cracking strength 64 per cent. greater than those of class 1.

Class 5 beddings were a combination of the earth beddings and the concrete cradle just described. The bottom of the trench was shaped to fit the lower quarter of the circumference of the pipe and the spaces between the pipe and the sides of the trench, about 3 in., filled with 1:8 concrete. These pipe showed a cracking strength of 46 per cent. greater than those of class 1.

The third class of concrete bedding for solid or firm soils was class 6. The trench was dug with a flat bottom and was about 6 in. to 8 in. wider than the outside diameter of the pipe. The pipe was laid in the trench and concrete poured in at the sides, care being taken to get the concrete well around the pipe. Tests



Methods of Bedding, Drain Tile or Sewer Pipe, in Testing for Supporting Power.

of this type of bedding were made with two grades of concrete. In class 6-A a 1:5 mixture was used and in class 6-B a 1:8 proportion. The pipe of class 6-A supported a load 96 per cent. greater than class 1 before cracking. Those of class 6-B developed a cracking strength 80 per cent. greater than that of class 1.

The tests of these classes also indicated that the supporting strength of a pipe after cracking depends upon the bearing power of the soil.

The pipe of these three classes showed a marked tendency to develop side cracks at or near, the top of the concrete at the sides. Where the side cracks in the pipe were below the top of the concrete it usually cracked opposite the crack in the pipe. In each case in Class 3, the concrete was cracked along the centerline at the bottom, the crack appearing simultaneously with the crack in the bottom of the pipe. In a great many cases the cradle was cracked near the lower ⅛ points by the continued application of pressure after the pipe had cracked.

The bedding designated as Class 7 was patterned after the Philadelphia method. This type of bedding or cradle would be equally effective in all soils firm enough to allow of the construction. The trench was dug a little wider than the outside diameter of the pipe and the bottom left flat. About 3 in. of 1:8 concrete was placed the full width of the trench and the pipe laid upon it. Concrete was then placed around the pipe to a height of 6 in. or one-fourth the inside diameter, above the bottom of the pipe. This bedded the pipe in concrete for a little over 90 degrees but furnished no side support whatever, as the top of the concrete was just about even with the surface of the ground.

The pipe of this class showed an average strength before cracking 82 per cent. larger than those of Class 1. As these pipe received no side support, they collapsed as soon as the main fractures were developed.

Tests were made of pipe bedded in "Concrete Cradles" for "Yielding Soils" as specified in the "Standard Specifications for Drain Tile." In Class 4-A a 1:5 concrete was used and in Class 4-B 1:8 concrete.

The trench was dug 10 in. wider than the outside diameter of the pipe and with a flat bottom. A 3 in. layer of concrete was placed in the trench and the pipe laid upon it. Concrete was then poured in at the sides up to the specified height of ¼ the inside diameter above the mid-height.

The pipe of Class 4-A showed an average strength before cracking 38 per cent. larger than those of Class 1, while those of Class 4-B supported 50 per cent. more load before cracking than did those of Class 1. The fact that the cradle of the leaner concrete gave the larger support is attributed to the fact that the pipe of Class 4-B were laid before those of Class 4-A and that cool weather and frosty nights prevailed after the cradle of Class 4-A were poured.

The pipe of these two classes usually cracked at or near the four ¼ points at the same time, though the side cracks were often at or near the top of the concrete. In all cases the concrete cradle cracked along the center line in the bottom, and often at about the lower ⅛ points of the pipe, at the same time the pipe developed fractures. After the cradles were cracked in the bottom, the two sections revolved around the lower outside edges and the pipe would support practically no load.

The bedding of Class 8 were very similar to the combined earth and concrete bedding of Class 5, except that the earth was dug away from the outside of the concrete so as to reproduce as nearly as possible the conditions prevailing when this type of bedding is used in yielding soils.

The concrete used in these beddings was proportioned 1:9. It was poured in cool weather and had developed only a comparatively small portion of its final strength at the time the tests were made.

The pipe of this class had an average supporting strength only 18 per cent. larger than those of Class 1. The concrete received no side support so that the load which developed the cracks in the pipe was the maximum. These tests indicated that this type of bedding would give but little side support other than that due to distributing the pressure over a larger area. In many soils this would result in a noticeable increase in supporting strength but in very wet soils the increase would be small.

These results might be summarized in three general statements, as follows:

1. The suppoting strength of tile laid in the "Ordinary" method is practically the same as the "Ordinary Supporting Strength" shown by the standard tests.
2. The supporting strength can be increased 25 per cent. by more careful earth bedding and 80 per cent. or 90 per cent. by the use of concrete cradles.
3. The supporting strength after the pipe is cracked depends upon the bearing power of the soil at the sides of trenches, irrespective of the type of the bedding.

In our description of the new Administration Building of the Hydro-electric Power Commission of Ontario in the May 3 issue of the Contract Record, we stated that storage batteries were installed for telephone and auxiliary lighting service. This should, of course, have read only for telephone service.

"Why don't they keep the streets a little cleaner,"
You ask with deep annoyance not undue,
"Why don't they keep the parks a little greener,"
Did you ever stop to think that THEY means
YOU?

First Church of Christ Scientists Dedicate a New Church at Winnipeg, Man.

New First Church of Christ Scientist, corner of Nassau St. and Water Ave., Winnipeg—Cost $100,000.

First Church of Christ Scientist

The First Church of Christ Scientist have made a notable addition to the churches of Winnipeg in their new building on the corner of Nassau and River Streets, which was recently dedicated for service. The new edifice is in the simple Greek Ionic design of architecture, built on the plan of a Greek cross. It is simple insofar as the exterior design is concerned. The foundations and exterior trimmings are Tyndall stone, while the exterior walls are buff-colored face brick.

The general idea of the Christ Scientist churches, to provide a large foyer for a meeting room wherein members may intermingle before and after service, has been carried out in this church. A cloak room has also been provided just within the main entrance. The main auditorium is above the level of the street and is accessible by four stairways. It is fitted with mahogany pews with accommodation for about 1,100 people. The floor slopes gradually toward the reader's platform. The organ loft is directly back of the reader's platform, and the organ will, when installed, be entirely obscured by a grill-work screen. The artificial lighting of the auditorium is carried out from the alcoves entirely. There is a Sunday school below the auditorium with seating capacity of 300.

The new church was designed by Jordan & Over, architects, Winnipeg, and built by the Fort Garry Construction Company at a cost of approximately $100,000.

Steam shovels—Circular No. 14, by the Osgood Company, Marion, Ohio, describing, with illustrations, their "18" ¾ yard, traction, revolving, steam shovel, adapted for sewer trench excavating only.

Concrete Street Railway Track Foundation Construction

The scarcity of permanent street railway track construction in many cities has been chiefly due to the fact that railway companies prefer to build some sort of temporary construction, which can be easily taken up to make repairs to the track, rather than lay any permanent type.

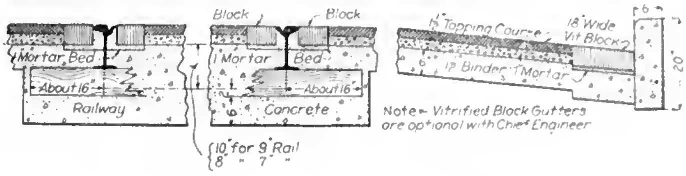
These temporary forms of construction have been the cause of a great deal of difficulty to street paving contractors in paving the remaining allowance of the street. Vibration due to poor foundations soon cracks the pavement near the rail, and requires repairs much sooner than would otherwise be necessary.

Mr. R. Keith Compton, chief engineer of the Baltimore Paving Commission, outlines in a paper read before the recent Pittsburgh Convention of the American Road Builders' Association the situation in Baltimore, how it was remedied, and the joint form of construction as carried on by the street railway and the paving contractor.

In the beginning of the year 1914 the situation in the city of Baltimore was thoroughly studied, both by the municipal engineers and the traction officials, with the result that the State Legislature of Maryland was appealed to by the municipality and a law was passed putting the character of foundation under the ties of the several street railway companies and steam railroads under the jurisdiction of the Paving Commission, with power to decide whether such foundation should be of plain ballast or concrete. The Commission decided that in heavy traffic down-town streets concrete construction, 6 in. thick, under and around the ties, was necessary, but that in the outlying suburban sections where the traffic is light and street development more or less of an uncertainty, awaiting property development, rock ballast could be used.

Work Together

The forces of the railway company and that of the paving contractor work in conjunction. The railway area is first graded out to the subgrade of the paving by the paving contractor. The railway company then takes charge and grades out to a point 6 in. below the bottom of the ties. New rails and ties are then installed where necessary, together with any new special work. The ballast is then placed and thoroughly tamped under the ties and up to a point 2 in. above



Form of track foundation construction used in Baltimore.

the bottom of the ties, the rails are brought to the proper grade and line, and when the entire construction is "tight" the penetration begins.

The grouting mixture is composed of 1 part cement to 2 parts sand, and is of about the consistency of thin cream. The mixture is applied without interruption to car traffic by the use of a small continuous mixer placed just outside of and parallel with the railway tracks, with a flexible chute, in two sections, to convey the grout from the mixer to the ballast. Starting on the downgrade end and working upgrade, the thin grout is penetrated into the stone ballast. When a car comes along the first section of the chute is thrown out of service and the second section is lowered to the ballast at about the ends of the ties and the mixer kept in service. After the car passes the first section is thrown back in service.

During this operation some movement occasionally occurs in the tracks, but there is a city inspector on the work at all times who hunts for and locates loose ties and they are immediately tamped up with green concrete.

The natural supposition is that sufficient movement of the ties and track would occur to injure the concrete while setting, but this is not true if the work is carefully handled and executed. On one street in Baltimore this work was successfully handled with five different lines of cars passing up and down the street with but 20 seconds headway at times during the day, while on another piece of work it was successfully handled with eleven different lines of cars passing over the special work with less than 20 seconds' headway at short intervals during the day. The resultant mixture is about 1 of cement, 2 of sand and 5½ of stone, with the concrete very dense, as the ballast has been thoroughly tamped and voids reduced to a minimum.

This ends the work of the railway company, as after this section of concrete is installed, the paving contractor again takes charge, installing the concrete base for the pavement immediately on top of the railway base, and then the paving.

As a rule, there is no bond between the paving slab installed by the railway company and the paving base installed by the paving contractor, because generally the former is several blocks ahead of the latter, and in the meantime the concrete slab has set.

One of the principal points gained by this form of construction is that it shows up very clearly every weak place during the progress of the work. All loose or poorly tamped ties are made apparent by the bubbling or oozing up of the grout as a car passes over. Failures in finished pavement are avoided by immediately tamping such ties, which in many cases would otherwise be overlooked. It has been found by careful cuts made in the finished work that this grout when properly applied penetrates the ballast to the subgrade, forming excellent concrete, and insures solid track construction, free from vibration.

From records kept and compiled by the Paving Commission it has been found that the total extra cost of this construction over plain ballast, including labor and material, is about 52 ct. per lineal foot of single track.

In the last two years about 10 miles (single track) of such construction have been installed in Baltimore by this process, in the busiest streets of the city, and our traffic interfered with to such a limited extent that no complaints whatever are heard from the traveling public during the course of the work. Included in the 10 miles of single track will be found all classes of paving within the railway area—sheet asphalt, wood block, granite block, vitrified block and scoria block.

In order to obtain good results with the penetration method, every detail must be carefully looked after by the inspectors, such as the quality and size of the stone composing the ballast, the tamping, and the mixing and placing of the grout. Frequent test holes should be cut in order to see that thorough penetration is secured, and wherever possible the penetration should be started at the downgrade end of a block and proceed upgrade.

To Supervise Elevator Construction

The John S. Metcalf Company, Montreal, have been retained by the State Governments of New South Wales and South Australia to make plans and supervise the construction of elevators for the bulk handling of grain. The same firm has also submitted a report to the Victoria Government. New South Wales proposes to erect a terminal elevator at Sydney with a capacity of 3,000,000 bushels; a terminal elevator at Newcastle with a capacity of 500,000 bushels and approximately 200 country elevators with varying capacities from 25,000 to 200,000 bushels. As the normal wheat harvest in Victoria is about equal to that of New South Wales, it is assumed that the elevator requirements of both states will be about equal. South Australia proposes to erect four terminal elevators with capacities ranging from 500,000 to 1,000,000 bushels, and about 110 country elevators of varying capacities. The John S. Metcalf Company have supervised, for the French Government, the building of a number of temporary elevators at some of the ports.

The Turbine Equipment Co.

The Turbine Equipment Co. have been awarded a contract to supply 4, single stage, De Laval, centrifugal pumps, capacity each 3,750 gals. per minute against a 95 ft. head, to the Imperial Oil Co. of Sarnia. The pumps will be direct connected to 75 h.p. motors. The Standard Chemical Co. of Toronto have also purchased a De Laval centrifugal pump, capacity 1¾ million gallons, to operate against a 125 ft. head.

Damp-proofing and Water-proofing

The Methods and Materials Used to Prevent the Disintegrating Action of Water on Completed Structures

By S. G. Webb*

The general subject of structural dampproofing and waterproofing as it confronts us to-day involves the methods and means of protecting structural materials against the disintegrating action of water. Masonry building materials are generally more or less porous and capillary in their structure, permitting the absorption and permeation of water. The presence of water in masonry is structurally injurious, due to its solvent action on any soluble content, but more particularly its disintegrating action by the expansive force that is manifested by the congealing of the water on freezing. While the subject of structural waterproofing and dampproofing deals primarily with the prevention of gradual decay and disintegration of structural materials, it also performs the useful and necessary function of providing more hygienic conditions for the benefit of humanity in general.

The subject of the protection of structural materials against the disintegrating action of water should, for the most comprehensive understanding, be considered under the two general divisions of waterproofing and dampproofing. The term waterproofing should correctly be confined to the consideration of methods and means of protecting subterra construction and structures intended for retaining and containing water under and against hydrostatic head. Consistent with this definition, the term waterproofing as a part of this great subject would apply directly to the methods of treating foundations, tunnels, reservoirs, cisterns, standpipes and similar construction. The term dampproofing should correctly be confined to the consideration of the methods and means of keeping water and dampness out of the superstructure of buildings. In accordance with this definition, dampproofing should involve the various methods of treating exposed walls above grade line to avoid the entrance or penetration of moisture and dampness into the structure.

Dampproofing

The subject of dampproofing, which we have already defined as correctly applying to a consideration of methods and means of keeping water and dampness out of the superstructure of buildings, may be very simply sub-divided into the three following classes, viz.:

A—Transparent coatings and treatments.
B—Opaque decorative coatings.
C—Special bituminous coatings.

Again, the above classification of dampproofing treatments may be further sub-divided. The method involving the use of transparent coatings may be subdivided into three quite characteristic sub-heads, viz.:

(1)—The Sylvester process.
(2)—Hot paraffine and waxes.
(3)—Special proprietary products.

(1) The Sylvester process is one of the oldest dampproofing treatments, and while it has been used to some practical extent, it is at the present time very seldom considered. The Sylvester process provides for the alternate treatment of a porous masonry surface with solutions of soap and alum. These solutions are preferably applied hot so as to insure good penetration and to accelerate the chemical reaction between the two materials. The theory of this treatment is to provide by inter-reaction of the soap and the alum, an aluminum salt of the fat contained in the soap, which will be deposited in the pores of the surface and tend to repel the moisture.

(2) The second classification of transparent dampproofing treatments covers all of the various methods which have been proposed and used, involving the heating of the masonry surface and the application of melted paraffine or wax. While a dampproofing treatment of this type can be made very effective its application is necessarily limited to only special cases where the high cost of its application is not prohibitory. The application can only be made slowly, as the surface has to be heated with a blow torch, and only when at the proper temperature can the melted paraffine or wax be applied to insure the proper penetration and absorption of the repellent material into the pores of the surface.

(3) The third class of transparent treatments, viz., special proprietary products, suggests quite an interesting and unfortunate chapter in the history of the development of the general subject of the preservation of structural work against the disintegrating action of water. Following the general recognition that one of the objections to concrete construction was its absorbent nature, there appeared on the market an almost innumerable number of transparent liquids presented with the most extraordinary and extravagant claims.

Early Products Inefficient

Practically all of the earlier proprietary transparent dampproofing products were nothing more or less than low melting point paraffines or waxes which had been melted and fluxed back into a volatile solvent. The theory of such a preparation is entirely correct, but unfortunately these several paraffines and waxes can only be dissolved in solvents to a very limited extent, producing a product that actually carries a very small amount of repellent base and an excessive amount of volatile material. On application to the surface, practically 90 to 95 per cent. of the original material would be lost by evaporation, leaving only a small residue deposited in the pores of the surface. It would require a number of repeated applications in order to leave deposited in the pores of the surface a sufficient quantity of the repellent base to provide any efficient dampproofing results.

The reason for not making more successful early progress on a transparent dampproofing treatment of this character is unquestionably the fact that the condition is by no means a simple one. A satisfactory transparent dampproofing material that is applied cold with a brush must be one that is practically colorless, as any tendency for the material to stain or discolor the surface is highly objectionable. Nature, unfortunately, has not provided many materials that offer possibilities for producing a product of this kind. The majority of products, when used in quantity sufficient to provide the necessary amount of total solids to give efficient dampproofing results, will impart such a color to the material that when used over stone that is more or less sensitive to discoloration, it will be-

* Sec'y of the Gypson Industrial Association, Inc., before the New York State Builders' Supply Dealers' Association.

come badly stained, and the injury will be more serious than the difficulty which it was originally intended to overcome.

The difficulties which the requirements for such a material presented, and the complaints which followed the use of so many of the inferior products, have resulted in the slow disappearance of a great number of products that originally appeared, and to-day there are only two or three of the materials on the market that were numbered originally among the great list of special products.

It is a problem that has involved a great deal of careful scientific investigation in order to select such materials which, due to their chemical affinity, can be so combined as to produce a synthetic base which has the properties of dissolving in the combination of solvents, to yield a product that will contain a comparatively high percentage of base so that when applied to a surface and the volatile material has evaporated, there will be a sufficient quantity of material deposited in the pores to fill them and change their natural absorbent nature to a negative repellent action.

Opaque Coatings

The second class of general dampproofing treatments, viz., opaque decorative coatings, may be subdivided similarly to transparent treatments affording a very simple consideration of this important part of the general subject of dampproofing. This classification is as follows:

(1)—Various cement washes.
(2)—Common oil coatings.
(3)—Special proprietary cement coatings.

(1) The first conception of applying an opaque decorative treatment is evidenced in the use of a mixture of cement and water applied with a brush for the dual purpose of obscuring any imperfections in the surface and giving an outer shell that is of a denser texture so as to protect the masonry from the penetration or absorption of moisture. While this treatment is more or less effective in uniforming the appearance of the surface, it hardly possesses any great or efficient dampproofing results. This is due to the fact that the cement is mixed with water, and when applied the water occupies a definite volume, and on evaporation leaves the surface full of small microscopic pores and apertures through which water can penetrate.

(2) The second class of opaque dampproofing treatments, viz., ordinary oil paints, has been tried at various times with unsatisfactory results. This is very obviously due to the fact that in contrast to a wood or metal surface, a concrete surface is chemically active, due to the presence of alkali. When a common oil paint is applied over wood or metal, there is no chemical influence to in any way interfere with its normal process of drying to a tough, elastic linoxyn film. When such a product is applied over a concrete surface, the condition is distinctly different.

(3) The third method of opaque dampproofing treatments, viz., specialized cement coatings, offers the greatest opportunity for producing effective and satisfactory dampproofing results. With a full knowledge of the physical and chemical characteristics of a concrete or masonry surface, it is possible to select raw materials and so treat and combine them as to produce a product that is in every sense a specialized cement coating. Such a product cannot be produced by any effort to re-adapt a common oil paint but must be built up fundamentally from special materials which, due to their physical characteristics and chemical properties, are suited for the production of a strictly specialized product.

Bituminous Products

The third class of dampproofing treatment involves the application of bituminous products to the interior of exposed walls. The treatments in the first two classes as outlined above are applied to the exterior of the superstructure; while the special bituminous products are distinct in being applied to the inside of the wall.

These products are black in appearance and usually of quite heavy body, being applied with a brush so as to provide a thoroughly continuous coating. They are characterized by indefinitely remaining tacky, and provide bond for a coat of plaster applied directly to the coated surface. It is to be emphasized that the prime purpose in the application of such products to interior walls is for dampproofing results, and the fact that they have the associated property of bonding a coat of plaster is distinctly secondary.

It has become a very general practice in construction work to provide for the application of such a dampproofing on the interior of all exposed walls, as it gives an element in the wall that will prevent the continuous penetration of dampness or moisture through the wall, which would injure and destroy the interior decorations and produce a damp and unhealthful condition.

The subject of waterproofing proper, as we have defined applying to the treatment of sub-terra construction and structures intended for retaining and containing water under hydrostatic head, may very correctly be divided into the two characteristic methods, viz., integral and membrane, each of which has further sub-divisions.

The integral method of waterproofing involves the addition of compounds to the concrete at the time it is placed, and becomes a unit or integral part of the mass. This method is also known as the rigid method of treatment in distinction to the membrane which permits greater movements and conformation in the structure without injuring the effectiveness of the waterproofing treatment.

Integral Method

The integral method has been received with a great deal of favor by engineers, and its application has been increasing quite rapidly. Various compounds which are used for general integral waterproofing requirements may be divided into two classes characterized by the physical condition in which they are added to the concrete, viz.:

(1) Finely powdered dry compounds which are mixed with the dry cement.

(2) Compounds either in liquid or paste form which are added directly to the water used to temper the dry mixture of cement and aggregate.

The products coming under the first classification may be further divided, due to their characteristic physical properties, into three classes, viz.:

(a) repellent; (b) non-repellent; (c) metallic.

(a) The repellents were the first integral waterproofing compounds to be generally used. These materials are usually the metallic salts of various fatty acids that import their characteristic repellent properties.

In the practical application of these dry repellent powders the material is mixed in proportions varying from 1 to 5 per cent. with the dry cement. The treated cement is then combined with the aggregate and tempered with water to proper consistency. For general concrete operations the repellent properties are greatly limited, due to their repellent action. The presence of quite a large percentage of hydrated lime is essential to serve as a ballast for the repellent material.

(b) The objection which has been taken by the engineering fraternity to the use of repellent products on account of the uncertainty in uniform results, has been a natural incentive to develop products which do not show this repellent action. These products are usually constituted on a basis of hydrated clay, aluminum hydroxide or some similar inorganic colloidal substance. In manufacture they are ground extremely fine so as to develop the largest possible surface area to intensify colloidal development. The partial efficiency of such materials is contributed by their void-filling value. They are also recommended as beneficial in lubricating the mass of concrete so that it flows together in a tighter and closer mass.

The limitations of such materials is due primarily to the fact that the products which are used, while of a characteristic colloidal nature, have not the capacity for sufficient colloidal development to fill out all the voids and apertures of a concrete mass and give a density that is absolutely impermeable.

(c) To complete the classification of various integral waterproofings which are mixed with the dry cement, metallic compounds should be mentioned. These products consist primarily of very finely ground metallic iron, and in their integral application are mixed dry with the cement in a similar procedure to other dry integral products.

The theory of the action of such products is the increase in volume that occurs from the oxidation of the iron. When the process is complete, in place of the fine particles of iron, there is developed the hydrated oxide, which occupies a volume much larger than is the case with the original iron particle. The great difficulty, however, in obtaining satisfactory results with the metallic powders when used in integral application is the fact that cement itself is strongly basic and the presence of the hydroxyl ions developed in the crystallization of the cement naturally inhibits corrosion and prevents the oxidation and development of the iron throughout the mass of concrete, which is essential for efficient results.

Liquid or Paste Forms

The second class of integral waterproofing compounds which are added directly to the water, either in liquid or paste form, has the great advantage of absolute certainty in even, uniform distribution throughout the concrete. These products are generally readily miscible with water, forming a colloidal suspension in the water, and as a result of thorough mixing of the water with the cementing materials, are correspondingly uniformly distributed throughout the entire mass. The compounds in this class may for the most complete consideration be divided into the three following classes:

(2) Compounds in liquid or paste form added directly to water used to temper concrete. (a) Unsaturated colloids; (b) extended colloids; (c) concentrated colloids.

(a) Under this class are included practically all compounds which contain unsaturated fatty acids that require reaction with the constituents of the cement in order to form the final waterproofing compound. These products are usually mixed with the water used to temper the concrete in proportions varying from 1:25 to 1:50.

The great general objection to the use of unsaturated colloids is the uncertainty of the effect upon the tensile and compressive strength of the concrete.

(b) Products included under the classification of extended colloids are not usually characterized by any tendency to enter into reaction with the constituents of the cement, but contribute their efficiency by the characteristic colloidal nature of the compounds themselves.

(c) The products included in this class are a further development of the extended colloids in that they contain only materials of a strictly colloidal nature, which are capable of contributing waterproofing value.

Insulating Membrane

The second general division of the literal subject of waterproofing differs distinctly from the integral method in that it does not attempt to treat the concrete, but rather to insulate it from contact with water by enveloping the structure in a continuous bituminous shield. The fact that the membrane is not a rigid or unit part of the structure permits a certain freedom of movement and action in the concrete without impairing the efficiency of the waterproofing treatment. This feature of the membrane system makes it suitable for waterproofing work not fully reinforced and liable to settlement or subject to vibration or shock, such as a railroad bridge.

It was early practice to simply coat the surface to be waterproofed with hot tar or asphalt, but it soon became evident that this was not sufficient as the coating would crack with any movement in the wall. It was therefore necessary to employ some material in addition to the bitumen in order to contribute the necessary toughness and tensile strength. Burlap and coal tar felt have been extensively used for this purpose and some very satisfactory waterproofing operations have been carried out with such materials. During the last few years considerably more attention has been given to the nature of the waterproofing felt and as a result there are now on the market especially manufactured felts which are both saturated and coated with bitumen and possess greater pliability and strength. By means of these felts more perfect membranes can be constructed as the strength and toughness of the felt permit greater distortion and twisting to accommodate it to the design of the work.

The bitumens most generally used for cementing the felt together in constructing the membrane are coal tar pitch, commercial asphalt and special asphaltic compositions.

Winnipeg Aqueduct Work Proceeds

Sub-contractors on the Greater Winnipeg aqueduct will be allowed to proceed with their contracts, pending the final report of the engineers now employed in making an investigation of the designs and construction, provided that the cement bases of the foundations on certain sections be so extended as to render their stability beyond any question of doubt.

This was decided upon at a meeting of the Greater Winnipeg Water District board, recently, after receiving an interim report from the investigating engineers, who had made a cursory examination of the aqueduct. A more extensive and probably a final inspection of the work is now being made.

Additions to Dominion Sheet Metal Plant

Two additions, 20 ft. x 100 ft. and 40 ft. x 80 ft. respectively, are being made at the plant of the Dominion Sheet Metal Company, Limited, Hamilton, Ont., manufacturers of "Premier" galvanized sheet. This company is sparing no effort or expense to give Canadian buyers of galvanized sheets a steady supply at this time when import shipments are negligible. This result has only been possible by high pressure work on the part of a thoroughly experienced staff and by having provided liberally in advance against present extraordinary conditions. In this connection it might be noted that not a pound of Canadian prime western spelter can be purchased today, though it is hoped that eventually the British Columbia product will be available.

Armstrong Cork & Insulation Company

An interesting booklet has been issued by the Armstrong Cork & Insulation Company, of Pittsburg, Pa., describing their Nonpareil high pressure covering for high pressure and superheated steam lines, boilers, breechings, feed water heaters, tanks and heated surfaces, in more detail than, we believe, has ever been before attempted by a manufacturing company. An interesting feature is a list of comparative tests made at the company's Beaver Falls factory, as a result of which they have been able to fix definitely the heat losses from various sizes of pipe, both covered and uncovered. These losses are also given in B.t.u., per lineal foot, per degree difference in temperature, for twenty-four hours. There are also included tables which show in a general way the most economical thicknesses of Nonpareil high pressure covering to use, based on different steam costs. A complete set of specifications covering the correct installation of these various thicknesses is also included in this very interesting and well-illustrated booklet.

Lighting the Panama Canal

The United States is largely indebted to the efforts of Swedish engineers for an economical means of lighting the Panama Canal. In Sweden the reefs and narrow inlets are a menace to skippers and fishermen, but the expense of engaging lighthouse keepers and providing them with the means of livelihood would be so great that many dangerous points had necessarily to be left unguarded. That resulted in Gustaf Dalen creating the self-tending lamp, which affords a practical and economical means of light. From that was finally evolved the Aga gas accumulator, which contains 100 times its own volume of gas, and is, at the same time, safe and nonexplosive. It can be fixed to burn for a year or even a longer time without personal attention. The Aga flashlight apparatus also makes it possible to give distinctive characteristics to lights, of any desired duration or combination, while another marvel of this economical device is the sunvalve, which extinguishes the light during the day, thus further diminishing gas consumption. It is that type of lamp that has been installed along the Panama Canal.—Eng. and Contracting.

The Stone & Webster Engineering Corporation are distributing a little booklet, entitled "Work Done and Work Doing," which lists the various items of development work handled by this company in the recent past.

Personal

Mr. M. T. Cantell has been appointed municipal engineer of St. Vital, Man.

Mr. R. M. Hannaford, assistant chief engineer of the Montreal Tramways Company, has been elected president of the Canadian Railway Club.

Lieut.-Col. George G. Nasmith, Ph.D., C.M.G., who has rendered valuable service at the front as analyst and in an advisory capacity on sanitary work for the Canadian forces, is to be honored by the University of Toronto at the convocation to be held May 19th, with the honorary degree of LL.D.

Mr. Robert S. Low, of the well-known Ottawa contracting firm, Bate, McCutcheon & Co., has been appointed honorary colonel of the 4th Overseas Pioneer Battalion. Colonel Low was engaged in the construction of Valcartier camp and received great credit for the manner in which he prosecuted that work.

Mr. Stanley H. Frame, A. M. Can. Soc. C. E., has recently received the appointment from the Dominion Government as District Hydrometric Engineer with the Irrigation Branch, Department of the Interior, Calgary. For the past three years he has held the position of assistant to the city engineer of Calgary.

Mr. Augustin Frigon, C.E., has resigned from the firm of Surveyer & Frigon, consulting engineers, Montreal, to become engineering manager of the Canadian Siegwart Beam Co. Mr. Frigon is a graduate of Laval University and for several years has been a member of the Faculty of that university. The firm name of Surveyer & Frigon has been changed to Arthur Surveyer & Co.

Obituary

Lieut. Frank J. Lawson, B.A.Sc., recently with the engineering department of the city of Calgary is dead of wounds received in France. Lieut. Lawson was the only son of the well-known architect F. J. Lawson of Calgary.

Miscellaneous

The opening of the Thorold Engineers' Club took place on the evening of the 4th inst. Chief Engineer Weller of the Welland Canal formally declared the Club open. He referred to the excellent progress made in Thorold in the past three years with its paved streets and many new industries and hoped the good work would continue. Other speakers were Mr. F. H. Keefer, President Cameron and Secretary Clifford.

A union church is to be built at Conquest, Sask., by the Methodists and Presbyterians of that town at a cost of $8,000. The design of the new structure is an economic adaptation of classic style, and its auditorium will have a seating capacity of 250. The contractor is Peter Wick, of Conquest, and the architects are Storey & Van Egmond, of Regina.

Returning from a tour to New York and Philadelphia, Mr. Paul E. Mercier, chief city engineer of Montreal, has issued instructions that asphalt in that city must be laid at not more than $1.90 a yard, as compared with a minimum of $2.14 in previous years. There are about 400,000 square yards to be laid in Montreal this year, and if the work can be done at this figure per yard, the total cost will be $240,000 less than the estimate, which was made on the basis of $2.50 a square yard. Mr. Mercier will also, if he receives the approval of the Board of Control, make improvements in the city's asphalt plant, that will, he declares, save another 10 per cent. on the cost of asphalt at the plant.

Mainly Constructional

East and West—From Coast to Coast

Messrs. Peden & McLaren, architects, 20 St. Alexis St., have removed to 54A Beaver Hall Hill, Montreal.

Mr. L. J. Bigonesse, architect, has removed from 92 Notre Dame Street East, to 60 Notre Dame Street East, Montreal.

In future Montreal will call for public tenders on all work connected with streets and sewers; the city will also tender on the work.

Building activity in the city of Quebec still continues. Fifty-three permits were granted, amounting to $121,495.00, in one week recently.

Thousands of dollars have been expended by Messrs. Kennedy & Sons on the revolutionizing of an old steel plant in Collingwood, Ont., and they have now a staff of over sixty hands working.

During the month of April this year there were thirty-two building permits issued in the city of Woodstock, for the total sum of $25,260.00. This is just about twice the amount for the same period in 1915.

In the city of Galt, Ont., during the month of April there were twenty building permits issued representing a value of $13,210.00. For the year up to the present there have been 27 permits issued amounting to $18,360.00.

Contractors in Brandon, Man., complain that there is unfairness in the letting of contracts by the Dominion Government. They claim that they are not given sufficient time to obtain blank tender forms from Winnipeg and submit their tenders.

The new Rudkins Brass and Iron Co. foundry in Peterboro, Ont., is now in operation, under the managership of Mr. Wm. Rudkins, and is now filling a large number of orders. Additional machinery is to be installed and work will be proceeded with on a much larger scale than at present.

Building permits issued in St. Catherines, Ont., for the month of April show that there is considerable activity in that line. The total value of the permits for that month was $78,775, amongst them being one to the Dominion Food Co., Ltd., for the erection of a factory building at a cost of $14,000.

Thomas Kelly, head of the Winnipeg contracting firm of Thomas Kelly & Sons, has returned to Winnipeg to face charges of theft, receiving money under false pretences, and perjury, having been unsuccessful in his fight in the supreme court of the United States against an order for his extradition to Canada.

A factory bylaw is being submitted to the ratepayers of Port Hope, Ont., whereby Mr. Brandon, the head of a new concern, agrees to establish a manufacturing business in the building which was erected for the International Tool Steel Co., and to put the building in repair and start manufacturing within the first year.

Satisfactory progress is being made with the Toronto-Hamilton highway in the district around Burlington, Ont. The road is now being graded between Burlington and Walker's Crossing. Engineer Baldwin, who is in charge of the work there, says it is probable the road will be completed through the town by the end of June.

Mr. John E. Pearson, architect, Toronto, stated before the Commission appointed at Ottawa to inquire into the cause of the Parliament Buildings fire on February 3, that there was in his opinion no evidence to show that there had been an explosion or anything in the spread of the fire which could not be accounted for by the structure of the building.

There were 38 building permits issued in the city of Vancouver for April 1916, representing a value of $64,605.00, as compared with 86 for April, 1915, representing a value of $31,754.00. The total number of permits issued for the first four months of this year was 125, value $358,350.00, while for the same period last year there were 278 representing a value of $302,791.00.

Western Ontario city engineers have been discussing the advisability of grouping the municipal departments of each town or city in connection with engineering. It seems to be the general belief that these departments could be run more efficiently, were they operated and directed from a central engineering department. Such is the reported opinion expressed by the city engineers of Berlin, Guelph, Stratford and Galt.

The nineteenth annual meeting of the American Society for Testing Materials will be held in the Hotel Traymore, at Atlantic City, June 27 to 30. The first day will be devoted to miscellaneous reports and papers on heat-treatment of steel. Reports on steel and iron, and on tests and testing will be presented the second day. The last two days will be devoted to reports on cement and concrete, ceramics and road materials, non-ferrous metals, cast iron and miscellaneous material.

Work on the Bloor St. viaduct in the city of Toronto, Ont., is progressing, and the contractors on the Don Valley section, Quinlan & Robertson, have the first 150 foot arch up and half riveted. One of the biggest parts of the work will be the building of the timber false work, into which the concrete will be poured. The contractors for the Rosedale section are further advanced and will be putting down the floors before long . The contractors on both sections are considerably ahead of their time contract with the city.

A contract for the construction of a five storey garage to be erected at the corner of Laurier Ave. and Durocher St., Outremont, has been let by Mr. Wilfred Duquette to L. A. Ott & Co., 611 New Birks Building, Montreal. The building will be 86 x 50, and 47 feet high. It will be constructed of reinforced concrete, faced with brick. The mushroom system will be used. The floors will be of reinforced concrete. A freight elevator to convey the automobiles, either to the basement or the upper storeys will be installed. The architect is Mr. S. Frappier, of Montreal.

Preliminary work for foundations of a big C. P. R. electric crane on the company's wharf at Vancouver has just been started. The crane, which is built to the design, and will be installed under the supervision, of Mr. H. Rindall, the C. P. R. chief engineer at Vancouver, will be of the upright mast and swinging boom type with a 50 ton capacity. The mast will be 50 feet high and the boom will be 100 feet long, both being of steel lattice. The Cotton Company, Limited, were awarded the contract for the foundations, in which there will be used about 250 yards of concrete.

The Toronto Harbor Commission have awarded the contracts for the construction of a concrete harbor-head wall and cribs, between Bathurst and Brock streets to two local firms, the Robert Weddell Company and the Dredging and Dock Company. The former company is to handle section 1 of the work, which includes a new harbor-head wall from the west end of the present Government wall to the west boundary of Spadina Avenue, and the latter company have the contract for section 2, consisting of construction work from Spadina Ave. to a point between Spadina Ave. and Peter St.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks Sewerage and Roadways

Fernie, B.C.
The City Council are having plans prepared for about two miles of sewer in the Annex. Engineer, William J. Ramsey. Approximate cost, $14,000.

Ingersoll, Ont.
The Town Council propose to lay a quantity of tarvia pavement on concrete base. Clerk, W. R. Smith.

Kenogami Township, Que.
The Township Council propose to expend $6,000 on roads during the season. Secretary, T. L. Potvin, St. Cyriac, Que.

Moncton, N.B.
The City Engineer, J. Edington, will receive tenders until noon, May 25th, for the construction of about 14,200 square yards of pavement, either creosoted wood block, bitulithic asphalt or reinforced concrete.

Quebec, Que.
The Ciay Council propose to call for tenders on the construction of pavements and sidewalks and the supply of an asphalt plant. Engineer, W. D. Baillairge.

St. Lambert, Que.
Tenders on the construction of concrete pavement on Waterman and Bridge Streets, will be received until noon, May 22nd, by the Town Secretary, James R. Beatty. Engineer, E. Denkwater.

Toronto, Ont.
The Board of Control will receive tenders until May 23rd for a quantity of sewers, asphalt and brick block pavement, concrete curb and grading. Plans at office of the Works Wepartment.

Usborne Township, Ont.
Tenders will be received until 10 a.m., June 23rd, for the construction of the Bock Creek Drain, estimated to cost $7,468. Plans and specifications at office of the Township Clerk. Francis Morley, R. R. No. 1, Granton.

Wainfleet Township Ont.
The Township Clerk, J. Henderson, Marshville, Ont., will receive tenders until May 27th for the construction of a number of drains.

CONTRACTS AWARDED

Berlin, Ont.
The contract for laying a concrete paveemnt on Queen Street, has been awarded by the City Council to E. J. Holland, Ingersoll, Ont.

Edmonton, Alta.
The City Council have awarded a contract for the construction of about 75,000 feet of sidewalk to D. R. Fraser Company, 10149-97th Street.

Lanoraie, Que.
The Municipal Council have let a contract for roadwork to Stack & Leger, c/o the Secretary, L. J. Desrosiers. Approximate cost, $9,000.

Metcalfe Township, Ont.
The contract for the construction of the Ward Drain has been let by the Township Council to G. Brooks, c/o. the Clerk, Harry Thompson R. R. No. 2, Kerwood.

Sudbury, Ont.
The Town Council have awarded the contract for construction of about 1,800 square yards of bitulithic pavement to the Warren Bituminous Paving Company, Ltd., McKinnon Building, Toronto, at $2.65 per yard.

Public Buildings, Churches and Schools

Beamsville, Ont.
W. W. Lachance, 157 Main Street, Hamilton, has been appointed Architect for the proposed High School. Approximate cost, $20,000.

Beeton, Ont.
The Public School Board are considering the erection of a school at an approximate cost of $20,000. Architect not yet appointed.

John Wilson, Collingwood, has been appointed Architect for the proposed school. Tenders will be called shortly for the erection of a four-roomed brick building.

Dominion City, Man.
Tenders on the erection of a school will be received until May 22nd. Architect, F. R. Evans, 901 Confederation Life Building, Winnipeg. Steel, concrete, brick and Tyndal stone construction. Approximate cost, $20,000.

Dundurn, Sask.
R. M. Thompson, Architect, Masonic Temple, Saskatoon, is preparing plans of a school, estiamted to cost $12,000. Brick and concrete construction.

Fredericton, N.B.
Tenders will be called early next month for the erection of a Sunday School for St. Paul's Presbyterian Church. Architect, G. W. Kramer, 1 Madison Avenue, New York. Approximate cost, $30,000.

Montreal, Que.
The Roman Catholic School Board propose to build a school at Longue Pointe and tenders will be called. Architect, H. Bergeron, Longue Pointe. Brick and stone construction.

The Roman Catholic School Commissioners are having plans prepared for a school to be built in Notre Dame de Grace Parish. Architects, Audet & Charbonneau, 364 Dorchester Street.

Quebec, Que.
Private tenders for the erection of a chapel for the Patronage Laval will be called by the Architect, O. Beaule, 19 d'Aguillon Street. The contract previously reported awarded to J. Chevalier was for excavation only.

Rossland, B.C.
The School Board propose to build a school at an approximate cost of $50,000, of which sum $30,000 has been included in the estimates of the Provincial Government. Secretary to the Board, J. A. McLeod.

St. Andre Avellin, Que.
Tenders on the erection of a convent for the Sisters of Providence are being received by M. le Cure Belanger and the Architect, H. Bergeron, Longue Pointe, Que. Stone and concrete construction.

St. Jean de Dieu, Que.
The Corporation St. Jean de Dieu contemplate the erection of an addition to the Asylum, but tenders will not be called for some time. Stone and concrete construction. Approximate cost, $250,000.

St. Louis de Pintender, Que.
Plans are being prepared by L. Auger, 39 St. Jean Street, Quebec, for repairs to the Parish Church, estimated to cost $15,000. Work includes construction of galleries and painting.

Toronto, Ont
Gordon & Helliwell, Architects, Confederation Life Building, have prepared sketch plans of a hospital for the Women's College Hospital and Dispensary. Estimated cost, $125,000. Secretary, Miss J. F. Anderson, 55 Castle Frank Road.

Weldon, Sask.
Tenders are now being received for the erection of a four-roomed brick school, estimated cost $16,000. Architect, William Knox, 16 Tenth Street W., Prince Albert.

CONTRACTS AWARDED

Basswood, Man.
The general contract for the erection of a school has been awarded to Worswick Brothers, 125 Hart Avenue, Winnipeg. Approximate cost, $14,000.

Conquest, Sask.
The general contract for the erection of a Union Church has been awarded to Peter Wick, c/o. the Architects, Storey & Van Egmond, 1013 McCallum Hill Block, Regina. Approximate cost, $8,000.

Eastview, Ont.
The following contracts have been let in connection with the erection of a school: Steel work, Dominion Bridge Company, Sparks Street; plastering, Murphy & Morrow, 139 Waverley Street; painting, Higman & Son, 176 Rideau Street; electrical work, Charles Presby, 138 Irving Street

Farnham, Que.
The contract for electrical work in connection with the High School now in course of erection for the Protestant Board of School Commissioners, has been let to the Electrical Repair & Supply Company, Sherbrooke.

Finch, Ont.
The general contract for the erection of a school for the School Board of Section No. 3 has been awarded to Stafford R. Rudd, Madawaska Street, Arnprior. E stimater cost, $12,000.

Leclercville,, Que.
Work is progressing on the erection of a school, estimated to cost $8,000. General contractor, Ernest d'Aigle, Ste. Emelie de Lothbiniere.

Montreal, Que.
In connection with the erection of a Presbytery for Ste. Catharine Parish, the painting contract has been awarded to Joseph Guy, 325 Workman Street.

Port Colborne, Ont.
The general contract for the erection of a church for the St. James Congregation has been awarded to Ryan & Gardner, Welland, and work will start shortly. Approximate cost, $24,000. Stone and concrete construction.

Sherbrooke, Que.
The contract for roofing in connection with St. Michael's Cathedral, has been awarded to P. M. Hoadley & Company, 284 Beaver Hall Hill, Montreal.

Business Buildings and Industrial Plants

Brantford, Ont.
P. H. Secord & Sons, Ltd., 133 Nelson Street, are building a storage building, estimated to cost $4,000. Brick and concrete construction.

Hamilton, Ont.
The Grasselli Chemical Company propose to build an addition to their premises on Burlington Street, and have prepared plans. Frame and corrugated iron construction. Estimated cost, $18,000.

Mont Joli, Que.
Pierre Levesque, 115 St. John Street, Quebec, is preparing plans for premises to be built for La Banque Nationale, 75 St. Pierre Street, Quebec. Stone and brick construction. Approximate cost, $15,000.

Montreal, Que.
Antoine Dinardo, 590 St. Timothe Street, has commenced the erection of a garage and flats, estimated to cost $5,500. Brick and concrete construction.

Work has been started by Narcisse Bellehumeur, 12 Montgomery Street, on the erection of a store and flats, estimated to cost $3,500. Brick and concrete construction.

The City Council have started work by day labor on the erection of a temporary Fire Station on Bickerdike Street. Brick and concrete construction. Estimated cost, $4,000.

Turner Bros., Ltd., 34 St. Peter Street, are about to start work on a warehouse, estimated to cost $18,000. Frame and concrete construction.

North Battleford, Sask.
Plans have been prepared for an addition to the premises of Pickel & Johnstone, Main Street. Estimated cost, $7,000.

Ottawa, Ont.
Millson & Burgess, Union Bank Building, are preparing plans of a Club House for the Knights of Columbus, to cost about $25,000. Tenders will be called shortly. Brick and concrete construction.

Charles Joyce, 883 Somerset Street, will shortly call for tenders on the smaller trades in connection with the stores and apartments which he is building.

Port Glasgow, Ont.
Galbraith & Dromgole, Rodney, are considering the rebuilding of fish houses recently destroyed by fire. Estimated cost, $3,000.

Quebec, Que.
Plans have been prepared by A. L. Robitaille, Lindsay Building, St. John Street, for the conversion of a building into a bank for Lacaisse d'Eco. Nomie de Quebec. Estimated cost, $8,000. Tenders will be called shortly.

St. John, N.B.
The sum of $500,000 for rebuilding the elevator owned by the Intercolonial Railway has been included in the supplementary estimates.

St. Thomas, Ont.
Arthur Harbour, East and Talbot Streets, is considering extensive interior alterations to a business blcok, estimated to cost $10,000. Architect not yet appointed.

Sudbury, Ont.
The Town Council are having plans prepared for a power station to be built on David Street at an approximate cost of $15,000. Architect, Victor L. Morgan, Wilson-Greenwood Block. Brick, concrete and steel construction.

Toronto, Ont.
H. T. LePage, 1152 Dundas Street, is building a factory, estimated to cost $25,000. Steel and brick construction.

Winnipeg, Man.
The Breen Motor Company, Broadway and Sherbooke Street, propose to build a garage at an approximate cost of $15,000. Brick and concrete construction.

Woodman & Carey, Lindsay Building, have prepared plans of a publishing house for the Stovel Company. Estimated cost, $225,000. Brick and limestone construction.

CONTRACTS AWARDED

Barriefield, Ont.
The contract for construction of frame buildings at the Camp has been let by the Department of Militia to the Kingston Construction Company, Brock Street, Kingston. Approximate cost, $12,000.

Belleville, Ont.
The general contract for the erection of a storehouse for W. S. Cook,209½ Front Street,has been awarded to R. P. White, 46 Grove Street, and work has started. Stone and brick construction. Approximate cost $3,000.

Brandon, Man.
The Imperial Oil Company have let the contract for the construction of a warehouse and tanks to A. E. Bullock, 202 13th Street. Frame and reinforced concrete construction. Approximate cost, $10,000.

The general contract for the erection of five stores for G. R. Coldwell, 122 18th Street, has been let to F. C. Lissaman, 812 11th Street. Brick construction. Approximate cost, $10,000.

The general contract for the erection of a store for Doig, Rankin & Robertson, has been awarded to A. E. Bullock, 202 13th Street. Stone, concrete and brick construction. Estimated cost, $39,000.

A. E. Bullock has been awarded the general contract for an addition to the premises of the Crescent Creamery Company, 1321 Rosser Street. Estimated cost, $4,000. Brick veneer construction.

Brantford, Ont.
In connection with the erection of a storage building for the American Radiator Company, the contract for installation of a sprinkler system has been awarded to the Canadian General Fire Extinguisher Company Ytd., 1200 Dundas Street, Toronto.

Dundas, Ont.
The contract for masonry and carpentry required in the erection of a store and residence for H. Cohen, King Street, has been let to the Dickson Building Company, King Street, heating and plumbing to Louis Gies, King Street; electrical work to W. G. Laird, and store front contract to Kawneer Manufacturing Company, Guelph and Toronto.

Galt, Ont.

The general contract for alterations to the premises of the E. J. Coles Company, 493 Dundas Street, has been awarded to A. J. McKinney, Ingersol Avenue. Approximate cost, $10,500.

Pipe Lengths on Light Bents Hold Mains Down During Tests

Water mains under test have to be kept from pulling apart longitudinally, rising vertically and creeping sidewise. The longitudinal movement is pereventable by the same bracing that holds the cap on. Sidewise movement can be easily prevented by blocking and wedging the pipe in between the opposite banks, which are usually quite close.

To prevent the vertical movement some contractors backfill high over the normal top of the trench. This method does not serve well if the test pressure is high, and, in any case, is wasteful, as the trench usually has to be re-excavated for quite a length to permit the removal of the cap and the continuance of the line. Another way is to load extra pipe lengths on the main under test, using supports erected according to the individual judgment of the handy-man or calker who happens to be doing the work.

A systematizing of the latter method —or an adaptation of the two if the test pressure is especially high—will save the water main contractor money if there are sufficient test sections on his job to warrant it.

A supporting platform can be made by sawing two 4 x 12 inch planks as templates, cross-connecting them securely and nailing a 2 x 12 inch plank on them. Two of these platforms should be provided, one for each end of the pipe. If it is intended to leave the main under test uncovered for more than one length, enough should be provided to carry back as far as the main has a tendency to rise. Light bents should be constructed sufficiently strong to sustain the load that may be put upon them, and of a height determined by the average depth of trench.

The templates should be set down on the main and the bents placed on them and secured by plank straps lightly spiked. Squared timbers are then laid on top of the bents parallel to the trench, and skids resting on the bank on each side placed on the timbers. Extra pipes can then be rolled onto the skids, using as many as are needed to obtain the desired weight, and wedged in place. The whole weight does not need necessarily to rest directly on the pipe—in fact, it is desirable that it should not. It should rest mainly on the banks, but the bents should be fitted in so snugly that to rise at all under the pressure the main would have to lift the entire weight. In the case of an exceptional trench depth the height of the tops of the bents could be adjusted to suit by blocking up. If when actually under pressure the main shows a tendency to rise despite the weight of all the pipes that can find a place on the skids, dirt to the amount required to overcome the tendency can be shoveled on it. This will occur only under a very heavy test pressure.

The advantage of this method lies in the fact that the greater part of the work is done at one time and not repeated. Once the templates and bents are built it is simply a case of blocking to suit. The method is reduced to a rule-of-thumb process. The units will be light enough to be handled and hauled from point to point without difficulty, and there need be no timber butchering. Another advantage is that the contractor need not waste labor placing a weight that is more than is required. He can roll on such pipe as he thinks are necessary. A water main, under test, does not jump suddenly out of a trench. It slides up slowly. If the man observing notices a tendency to do so he can have more weight rolled on as needed.

Treated Ties Save Growing Trees

Of the 3,000,000 cross ties used every year by the Chicago, Burlington & Quincy Railroad for replacement purposes over 70 per cent. are treated with a preservative. According to J. H. Waterman, superintendent of the railroad's wood-preserving plant at Galesburg, Ill., the millions of treated ties in their tracks now last from twelve to twenty years, whereas untreated they last on an average of eight years. In each of the twenty divisions of the Burlington system there are tracks for experimental purposes containing 26,000 treated ties of different species, which are all carefully inspected at least once a year for the actual results of treatment as shown by the service test.

Tenders and For Sale Department

To Contractors

Sealed bids for all trades required in making alterations and additions to a residence in Elm Ave., Toronto, will be received up to noon of **Monday, May 22nd, 1916.** Plans and specifications and all particulars may be obtained at the office of the architect.

FOR SALE STEAM ROLLERS

One single cylinder Sawyer Massey 13 tons; one double cylinder Waterous, 15 tons. Both in perfect condition. Apply to Box 196, Three Rivers, Que. 19-20

Steam Rollers Travel Slowly—Motor Truck Will Hasten Trip

Steam rollers are slow travelers. On road work much time has been wasted and the work delayed while the roller was journeying from one distant point to another. The Kelly-Springfield Steam Roller Company hauls rollers from the plant to the railroad yards for shipment on a 3½-ton Kelly-Springfield motor truck, having found this a much quicker way than to drive the roller under its own power. This method could be followed to advantage by road contractors if the distance is great enough to justify it.

Loading a steam roller on to a motor truck on the job, however, is a more difficult matter than it is to load it at the shop, but the difficulty can be easily overcome. Most platform trucks are equipped with winches, either motor-operated or hand-operated. One way to get the roller up would be to place inclined skids at the tail of the truck, and draw the roller up with the winch. Another method would be to run the roller up on the bank—which is quite frequently a feature of the general run of country roads—under its own power and drive it along, laying down planks to facilitate its journey over the soft ground to a point where the bank is somewhat higher than the truck platform. Skids could then be laid down over the intervening gap and the roller easily placed on the truck. These are but two suggestions. Confronted with the task of doing such a job the average truckman would quickly devise a good method.

Stone Pavement in Rochester Undermined by Flood

Maximum high water in the Genesee River at Rochester, N. Y., recently caused the collapse of 12 square yards of the Medina block stone pavement, with its concrete base. The pavement caved in to a depth of 10 feet.

The washout was apparently due to the existence of an abandoned stone sewer 3 feet 9 inches wide and 5 feet 3 inches high, which was constructed in 1832 and superseded in 1863.

The water from the river, which at the time stood about 5 feet above the top of this sewer, entered it either through, or under, the present bridge abutment, or between the present and a former buried bridge abutment.

The water broke through an old egg-shaped sewer 1 foot 9 inches by 2 feet 6 inches, and entered an existing sewer manhole west of the bridge 18 feet below the surface. Flooding of cellars might have resulted had not the new sewer tunnel, 8 feet square and 40 feet below the surface, been sufficient'y completed so that connections with the existing sewer were made. The only inconvenience occasioned has been the closing of Main Street to street car traffic, during which time the local trolley company has taken occasion to renew its tracks in this locality. An investigation of the river end of the abandoned sewer will be made when the water lowers.

Who Supplies the Heat?

As long as specifications are written we presume there will arise questions which will admit of two interpretations and in such cases one can only be guided by precedent and common sense. Just at the moment we are in touch with a dispute between an owner and a contractor as to whose duty it is to pay for the coal that heats the building during part of the construction period.

There does not appear to be any question but that precedent places the responsibility on the owner. Few contracts make mention of this item in the specification and this, so far as we can learn, has invariably been interpreted to mean that the owner of the building buys the necessary coal to keep working conditions as favorable as possible. There is one slight difference in the specifications in question, however, in that the following clause occurs:

> "Coal, water and electric current will be supplied by the owner for all purposes that the heating contractor may require to effectively prove and test the system during the time of execution and completion."

The actual point in dispute is that, though the heating system was proved and accepted on January 18, 1916, work continued by the plasterer and carpenter up to March 26. The owner claims that the general contractor is liable for the cost of the coal between these two dates.

We cannot see how the insertion of this clause in the specification effects in any way the relationship between the general contractor and the owner, or between any of the sub-contractors and the owner, other than the heating contractor. No single case has ever come to our attention where the contractor has been held responsible for the heating of the building unless it was so definitely stated in the specifications, and in such cases we may say it has led to an infinite amount of trouble.

The work in question is on a church in the province of New Brunswick, where the custom does not appear to be different from that in other provinces of the Dominion. The writer knows of at least two very recent cases where different contracting firms completed large buildings in the province of New Brunswick. No mention was made in the specifications about heating, and the owners assumed the responsibility without the question ever being raised. We fail to see how any interpretation could be put on the contract in question that would place any responsibility on the contractor to pay for the coal to heat the building. Possibly some of our readers have been up against experiences of this nature and if so we shall be glad to hear from them, either for publication or for our private information.

Mill Construction and Fire Hazard

No one who has witnessed a large conflagration can fail to realize that the all-timber building cannot withstand terrific heat if directly in the path of fire. On the other hand, buildings of fireproof construction with fireproof walls and roof, such as are usually built to-day, will be seldom ignited and may be easily protected. It is not feasible, however, to build entirely of a fireproof material, such as concrete, because of the difficulty of securing machinery to the walls and floors. For this reason some builders prefer mill construction for the interior. To meet this requirement and still provide a fireproof structure, as far as possible, is the problem which confronts the present-day architect or engineer.

Experience in fire protection suggests that there should be as little combustible material as possible in the construction and equipment; each floor should be entirely cut off from every other floor, and each part of the building should be equipped with fire extinguishing apparatus. The advantage of reinforced concrete, other than the difficulty mentioned above of fastening machinery to it, is its incombustible nature. Fires may be confined to one floor with practically no danger to the remainder of the building. It must be remembered, however, that buildings of almost any form of construction are often destroyed by the burning of their combustible contents. The floor area should thus be kept down to a minimum consistent with the convenient and economical operation of the plant, and especially in a mill construction building of large area should be divided into sections by fireproof walls to prevent the rapid spread of fire.

If a mill work building is necessary, it should be of slow burning construction. Enough wood must, of course, be used to insure strength and stability, but surperfluous wood surface should be avoided. It is a question of considerable importance just how the quantity of timber to be used should be disposed. No architect with a thought for fire hazard will ever plan for either manufacturing or mercantile occupancy those regular fire traps known as "light joist" buildings.

In machine shops and other plants requiring especially heavy floor construction above the ground level, steel beams are generally used. In such construction provision must be made to prevent failure by expansion or buckling when subjected to heat. It is obvious that where steel beams or posts are used, they should be protected from fire by some sort of sheathing. Another matter which should not be overlooked in designing a building is the consideration of special fire hazards incident to the character of the work to be done within the building. Sufficient statistics are available on almost every well-known manufacturing process to indicate just what elements in such processes are susceptible to fire. Such hazards should be segregated to a separate fireproof compartment where fire may rage without endangering the rest of the structure.

There remain, however, after the observance of the points of construction, the consideration of fire extinguishing apparatus. It is obvious to any well-informed person that the manufacturer who builds today without provision for an automatic sprinkler system, almost wilfully endangers, not only the life of the building, but the lives of his employees as well. There are many details to be considered in fire protection in designing a factory, and the subject is dealt with in some detail by Mr. Franklin H. Wentworth, of the National Fire Protection Association, in a paper which is reproduced elsewhere in this issue.

Why Were Public Tenders Not Called?

CIRCUMSTANCES of more than usual interest appear to surround the letting of contracts for re-construction going on in old Knox College, Toronto. This is Government work, and, as such, the regulations required by law to be observed in the letting of Government contracts would naturally be followed. Two of these regulations are (1) that public tenders must be called, and (2) that a fair-wage clause must be inserted in the agreement. For some reason or other neither of these rules, it is claimed, were observed. In one case, at least, too, the wording of the specification appears to have been such as to eliminate any possibility of competition. Thus, in the plumber's specification the name of certain materials that must be installed are given and the name and location of the manufacturer. We believe the Builders' Exchange of the city of Toronto have taken the matter up and are investigating the circumstances surrounding the letting of these contracts.

Canadian No. 1 Construction Battalion

That engineers are the backbone of the war is apparent, and the need for more is evidenced by the fact that a Canadian construction battalion has been authorized and is well on the way with its recruiting. Two companies are to be raised in Ontario and two in Quebec. Recruiting has been actively under way for the last few days in Toronto and already approximately 200 men have enlisted. Active recruiting will commence immediately in Montreal for the 500 engineers required for the Quebec section. It is expected the battalion will be completed in a very short time and will proceed overseas shortly afterwards.

The construction battalion will work in conjunction with the Royal Engineers, and their work generally will be repairing and replacing works destroyed; also work on the lines of communication. The unit, which will be known as No. 1 Construction Battalion, is under command of Lieut.-Col. Blair Ripley, a civil engineer who has had long and varied experience in construction work in different parts of the Dominion. During the past ten years he has been employed as construction engineer with the C. P. R., and during that time has been identified with the erection of some of the largest viaducts in Canada. He was engineer in charge of the C. P. R. grade separation at Toronto up to the time of his appointment as Lt.-Col. of the Construction Battalion. The unit will be composed of 1,040, officers and men, and will be specially attractive to engineers and construction men. It has been raised at the direct request of the British War Office, and every officer in the battalion will be a civil engineer. The men will be instructed in railway construction, bridge construction and such work, by men competent in these lines of engineering work, The general class of men required is bridge and building men, construction men, and all classes of skilled and unskilled railway workers.

The officers who have been appointed for the battalion under the command of Lieut.-Col. Ripley, are: Capt. and Adjt. T. R. Loudon; Capt. J. H. Byrne; Capt. R. R. Holland; Capt. A. R. Ketterson; Capt. H. G. Henson, paymaster; Capt. V. G. Davis, quartermaster; Lieuts.—G. O. Fleming; J. B. Heron; F. G. Cross; H. R. McQueen; O. P. Hertzberg; H. L. Gilmour; G. S. Grant; and V. A. E. Steel.

Recruiting in Montreal will be in charge of Capt. Ketterson, with Lieuts. Cross and McQueen assisting him.

Road Dragging Competition

By lending financial support to road dragging competitions, the Provincial Public Works Department hopes to greatly improve Manitoba country roads. Instead of only fifteen municipalities taking up the competitions, the government desires that the 110 municipalities participate. An instructor will be appointed to assist in the work for not exceeding two months. An organizer will be appointed to assist in forming the new districts. The government will make a grant of $2.50 a mile of road entered in the competition and dragged for a season not shorter than May 1 to October 31.

The Manitoba Good Roads Association inaugurated the road dragging competitions, and the contests will still be under the auspices of the association, which will get the usual grant from the government.

A. C. Emmett, secretary of the association, will likely be asked to accept the position of organizer of the competition and districts.

The Design of Highway Bridge Floors

Determination of Loads and Stresses—Discussion on Different Types of Surfacing Materials

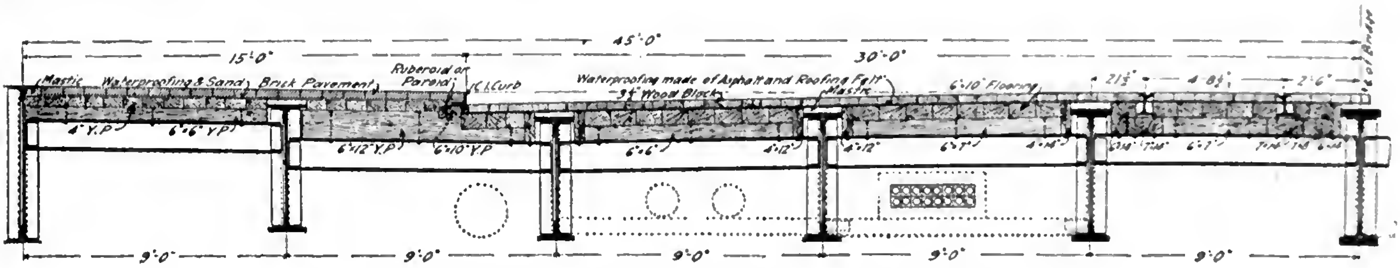
The design of highway bridges is more complicated than that of ordinary railroad bridges, partly because of the complications introduced by the paved floor and the provision necessary for supporting it and providing for its proper drainage, partly because of the varied character of the applied loads, and partly because of the difficulty in determining the width necessary to furnish reasonable accommodation for present and future traffic. The whole subject is discussed in a recent paper by Mr. Charles M. Spofford, before the Engineers' Society of Western Pennsylvania, with special reference to the floors and floor surfaces. The following extracts are from Mr. Spofford's paper:

For convenience in presentation, the subject will be treated under the five following main headings, each of which will be sub-divided:

(1) applied loads; (2) width of roadway; (3) wearing surfaces; (4) supports for wearing surfaces; (5) distribution of loads, computations and unit stresses.

Applied Loads

This subject may be treated under the following subdivisions:—(a) automobiles; (b) horse-drawn vehicles; (c) electric cars; (d) road rollers; (e) crowds of people; (f) miscellaneous loads, such as trains, water pipes, cables, snow, etc.; (g) uniform load and combinations of various live loads; (h) impact; (i) dead weight; (j) legal requirements.



A combined wood block and brick pavement.—Cost, including all other floor materials, 75c per sq. ft.

The uniform loads due to motor trucks are somewhat greater than the uniform loads usually specified for highway bridge trusses, but even were such trucks in common use no excess allowance over the ordinarily specified uniform load need be made for trusses or girders, except in the case of very short spans, as the probability of such a truck being on any bridge simultaneously with full uniform loading from other vehicles is practically nil.

As indicated by the following discussion of horse-drawn vehicles, it would appear that motor trucks are not used to handle the extremely heavy loads which occasionally cross city bridges.

In all large cities exceptionally heavy loads are occasionally hauled through the streets. Amongst the heaviest of such loads are machinery, parts of safe deposit vaults, steel girders, truss members, blocks of granite or other stone and heavy merchandise.

Experiments show that the weight of a crowd of people when carefully selected my reach the high figure of 181.3 lbs. per square foot. The writer once obtained a weight of 142.5 lbs. per square foot in his office by filling it with students selected at random. It is doubtful whether weights like this would ever occur in a mixed crowd consisting of people of both sexes and of varied heights. That extreme crowds may frequently occur on bridges is shown by experience, and that such loads may, over a portion of the bridge at least, amount to 100 pounds per square foot is readily believable. This is particularly true for bridges so located that large crowds may be attracted by reason of possible accidents on nearbly railway tracks or structures, by boat races underneath, by wrecks such as the recent overturning of a passenger steamer in Chicago on the river immediately adjoining a bridge, or by panic conditions occurring on the bridge itself.

Miscellaneous Loads

Amongst the miscellaneous loads which may be applied to bridge floors are electric trains, cable conduits, water and gas mains and similar structures. The weight of most of these may be given. Some allowance should be made for snow loads in the case of a highway swing bridge when in an open position, although it need not be considered in determining the stress with bridge in closed position, as the presence of snow on the floor would prevent the application of the full live load. The proper weight to be allowed for snow depends greatly upon the part of the country in which the bridge is located.

Combination of Live Loads

The question of what loads shall be combined in designing the various parts of the floor system is one that requires serious attention. The proper allowance to be made for impact on the floors of highway bridges is something upon which opinions vary greatly.

It would seem to the writer that a correct allowance for impact on highway bridges should properly vary with the character of the paving, the irregularity of an ordinary stone block pavement being such as to result in considerable impact, while a well-laid wood block pavement in good condition would produce but little impact.

Dead Weights

The following values may probably be safely used in determining the dead weights of bridge floors:

	Lbs. per cu. ft.
Hard (yellow) pine, 4 lbs. per ft. B. M. (Where protected by waterproofing and always dry; otherwise use 4½ lbs.	48
Creo-resinate yellow pine paving blocks ...	65
Spruce and white pine, 2½ lbs. per ft. B. M.	30
Bricks, pressed and paving	150
Portland cement concrete	160

Tar concrete (base for asphalt walks, etc.)	125
Silician rock (Simpson Bros.)	140
Trinidad asphalt (Barber Asphalt Co.), refined	74
As laid	140
Granolithic or artificial stone	150
Pavements (exclusive of sand cushion):	Lbs. per sq. ft.
6-inch granite block	80
4-inch brick	50
4-inch wood block (creo-resinate)	22
Roadway waterproofing:	
1¼ in. thick (felt, roofing pitch, sand and road pitch)	12
Buckle plates	10 to 20

Width of Roadway

The width of roadway necessary to provide for traffic of various quantities and intensities has an important bearing upon the design of the floor, and the writer has in consequence collected a considerable amount of data upon the subject.

The width of ordinary horse-drawn vehicles as measured in the streets of Boston is given in the following table, in which (a) equals distance out to out of hubs; (b) equals distance out to out of wheels; (c) equals distance out to out of whiffletrees:

	(a)	(b)	(c)
Hay wagon	7.75	7.00	8.00
Heavy express	7.65	6.70	7.90
Heavy express	7.80	6.70	7.60
Ice wagon	7.40	6.60	7.00
Hack	6.08	5.25	6.83
Coal wagon (3-horse)	8.50	....	10.83

Statistics upon width of and traffic upon various streets may be useful in determining the question of proper width of bridges. It should be borne in mind, however, that the capacity of a bridge in vehicles per hour is considerably greater than that of a street because of the freedom from interruption by traffic on intersecting streets and by vehicles stopping at the curb to discharge and receive freight and passengers.

Wearing Surfaces

Wearing surfaces for highway bridge floors may be classified under the following heads: (a) plank, (b) stone block, (c) wood block, (d) brick, (e) asphalt, (f) miscellaneous.

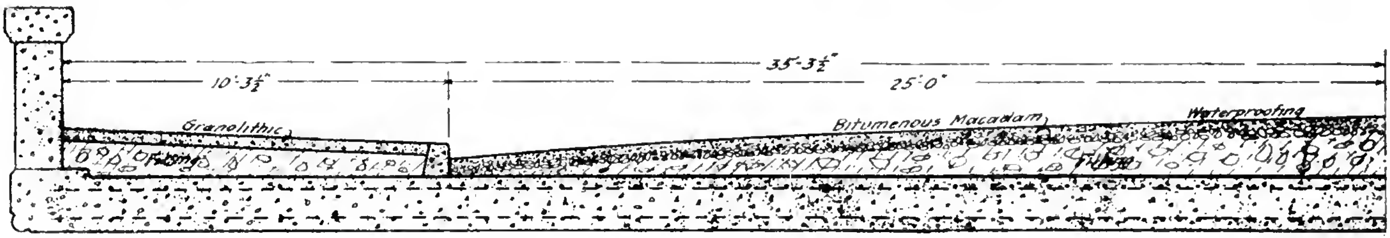
Plank

Such floors are commonly used for country bridges. They have also frequently been used for movable city bridges carrying heavy traffic where lightness of floor is important for economical operation, as well as for low cost of permanent structure, and has been considered as more important than the disadvantage due to frequent renewal of a plank wearing surface. The introduction of wood block pavement and of certain patented forms of wood pavement has, however, made it possible to construct a light floor much more durable than a plank floor and has in consequence done away, in part at least, with the temptation to use plank floors for city bridges except for bascule bridges, the floors of which must be so constructed that they will not slip off when the bridge is raised. Even if it is planned to use wooden sheathing at the outset to reduce the first cost of a given bridge, it would, nevertheless, seem wise to design the permanent structure to carry the weight of a wood block floor, as the additional cost would not be large and increase of traffic would probably eventually result in the demand for a better floor.

The common type of wooden bridge sheathing consists of two-inch spruce planks planed on one side to 1⅞ in. thick, laid either diagonally, at an angle of 60 degrees, or at right angles to the axis of the bridge, and supported on an under floor of untreated yellow pine to which it is nailed.

The life of spruce sheathing on bridges carrying heavy traffic in a wet summer, such as the past summer has been in Boston, may not be longer than from six to ten weeks, and the sheathing may have to be replaced five or six times per year, so that it is evident that it is bound to prove unsatisfactory. Attempts have been made in Boston to lengthen, by the use of preservatives, the life of such sheathing on bridges where, because of the lack of strength of the structure or for other reasons, the laying of a thicker and heavier pavement is impracticable. A number of preservatives have been tested and found to be unsuccessful. The writer is informed that Tylose preservative has given the best results and that planks coated with this on both sides have lasted 13 weeks, compared with 10 weeks for untreated planks laid alongside. Tarvia has been tried without success.

Untreated spruce sheathing in place on Boston bridges, laid in accordance with the specification recently quoted, costs about $38 per 1,000 cubic feet, $10 of which is the labor cost of removing the old sheathing and laying the new. This total price is equivalent to 7.6 cents per square foot.



Concrete arch bridge with a bituminous macadam roadway and granolithic walk.

Stone Block

Stone block pavement is very durable and admirably adapted for heavy traffic. It is expensive, both in first cost and in the weight it imposes upon the structure.

In Boston, it has been the custom to lay this paving on a sand cushion varying in thickness from 1 in. to 3 ins., the sand being necessary to take up the irregularities which occur in the blocks. The nominal depth of the blocks commonly used in Boston is 6 inches; in Philadelphia 5-inch blocks are used, and in Pittsburgh granite and limestone blocks varying in depth from 5 to 7 inches are specified. The length of granite blocks varies from 8 to 12 inches and the width from 3½ to 4½ inches.

Stone block pavement cannot be used on bascule bridges, as it would shift or slide as the bridge is raised.

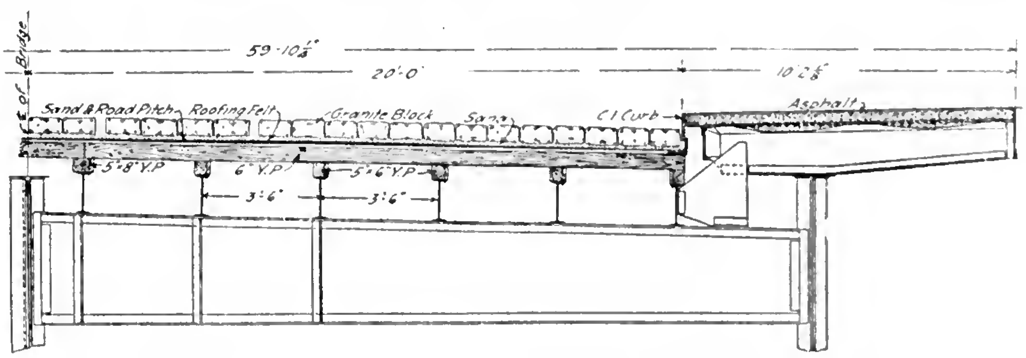
The cost of stone block pavement with pitch joints laid in place in Boston, exclusive of sand cushion, is at the present time about $2.50 per square yard. Its weight is about 90 lbs. per square foot.

Wood Block Pavement

Wood block pavement seems to be especially suitable for bridges, since, in addition to providing an excellent wearing surface, it is light in weight and regular in thickness, making it possible either to eliminate the sand cushion or to reduce it considerably in thickness. Great care must be taken in laying this paving to insure satisfactory results. The blocks should be thoroughly impregnated with preservatives, and expansion joints should be provided. The supporting surface should be sufficiently rigid to prevent disintegration due to deflection.

Experience in Boston would indicate that it is undesirable to lay wood block pavement directly upon a plank floor, or on other hard bearing surface, since the blocks are not uniform in thickness. A layer of asphalt mastic three-quarters of an inch thick, made of one part of asphalt and six parts of sand properly mixed and laid hot, has given good results on Boston bridges with timber sub-planking. Philadelphia specifications require the blocks to be laid on a layer of sand and cement 1 inch in thickness, mixed dry in proportions of one part of cement to four parts of sand, and sprinkled with water immediately before the block is laid.

Wood block pavement may be safely used on bascule spans if properly fastened. Mr. J. B. Strauss, of the Strauss Bascule Bridge Company, states that it is his practice either to toe-nail the blocks directly to the sub-planking, or else to lay steel angles spaced 4 feet to 6 feet apart and spiked to the sub-planking, these angles, which are laid at right angles to the centre lines of the bridge, being intended to act as shelves when the bridge is raised.



A granite block road floor on a sand cushion, with an asphalt sidewalk- Cost, 60c. per sq. ft.

Hexagonal wood blocks are sometimes use. The makers claim that such blocks knit together in such a manner as to equally distribute traffic loads, and that blocks as thin as 2½ inches may be used satisfactorily for bridge floors. The expansion of such blocks is radial and is said to be much less than that of rectangular blocks. The Public Works Department of Chicago is about to try this form of blocks, cut from young cypress, on a bascule bridge at Belmont Avenue, laying the blocks directly on a solid plank floor 6 inches thick. Every third block is to be face-nailed directly into the sub-planking, the fact that the blocks are all heart wood making it possible to do this without splitting the blocks.

The cost of 4-inch wood block pavement as laid in Boston in 1914, with a five-year guarantee, averages about $2.50 per square yard in place, exclusive of cushion. It varies greatly, however, with the density of traffic.

Brick

Brick pavements may be used on bridges with satisfactory results. Such a pavement is cheaper than a wood block pavement and lighter than a stone block pavement. The bricks should be laid on a sand or mastic cushion similar to those described under the heading "Wood Block Pavement," and expansion joints should be provided. The city of Philadelphia specifies that the bricks should be 3½ ins. in width, 4 ins. in depth, and 8½ ins. in length, and that they shall not vary in depth and width to exceed ⅛ in., nor in length to exceed ½ in. They are also required to have raised lugs on one side not to exceed ¼ inch in height. The cost of brick pavements in place in Boston is about $1.75 per square yard exclusive of sand cushion.

Asphalt

Asphalt pavements should not be laid on bridges except where a floor base of concrete or other rigid material is employed. It should not be used on bascule spans.

Miscellaneous Pavements

A patented pavement, the Shuman pavement, consists of narrow parallel wooden strips of maple, treated with asphalt and fastened together in the form of blocks about 2 feet wide by 5 feet to 7 feet long by 4 inches thick. This pavement is apparently no longer manufactured by the patentees, but it is still built by the city of Boston, which has the patent rights for municipal work in that city. This pavement is light in weight and can be securely fastened to a timber underplanking, making it especially desirable for bascule spans.

Macadam paving is probably seldom, if ever, used for other than reinforced concrete or masonry bridges, where it can be laid on a solid base in the ordinary manner used for street construction.

Supports for Wearing Surfaces

It is the writer's opinion that timber flooring consisting of yellow pine ties and planking is most satisfactory for ordinary city bridges. Such a flooring has been used with considerable success in Boston, and is the commonly adopted type of flooring in that city. Floors with timber sub-planking are also recommended for New York City bridges by Edward A.

Byrne, Assistant Chief Engineer, Department of Bridges, New York City.

The principal advantages of this form of flooring are its very considerable rigidity, combined with lightness and consequent cheapness for the bridge as a whole. If the timber planking is laid with tight joints such a floor is practically fireproof.

The life of yellow pine planking in bridge floors, when properly protected by waterproofing, is probably not less than twenty years, while the steel superstructure has been known to give out in less time than this.

Buckle plate floors have proven satisfactory for stone block pavement. They are not especially rigid and may give considerable trouble with wood block pavements.

Concrete and reinforced concrete floors and brick arch floors, while durable and rigid, are very heavy, and in consequence impose an unnecessarily heavy load upon the permanent structure.

Distribution of Load

The determination of the correct distribution of the applied load over the various supporting members of the floor system is a problem which does not admit of a definite solution, owing to the extreme statical indeterminateness of the system. The problem may be considered, however, under two heads: (a) the effect of the paving or other surfacing in distributing the load over its supports, and (b) the effect of the continuity of the supporting surface and of the street car rails in distributing the load over the stringers.

Distribution Due to Paving

The distribution under (a) is evidently a matter of experimental investigation, and so far as the writer is aware, no such investigations have been made. For a sheathed floor in good condition, considerable distribution may occur, but when the sheathing is old, none can be counted upon. It would, therefore, seem wise to make no allowance in the design of such a floor for the distribution due to the sheathing.

In the case of stone block paving laid on paving sand over a layer of waterproofing material, the distributing effect of the sand and waterproofing is considerable, and it would seem justifiable to consider a wheel load as distributed uniformly over the base of a frustrum of a pyramid with sides sloping at forty-five degrees and with an upper surface equal to the base of the paving block.

For brick or wood block paving a considerable arching effect may perhaps occur, but it would seem unwise to count upon this to distribute the load, which should be considered as distributed in a similar manner to that suggested for stone block pavement provided the pavement is laid upon sand or other yielding substance. If laid directly upon planks or other hard surfaces, no distribution can be counted upon other than that over the base of the block itself.

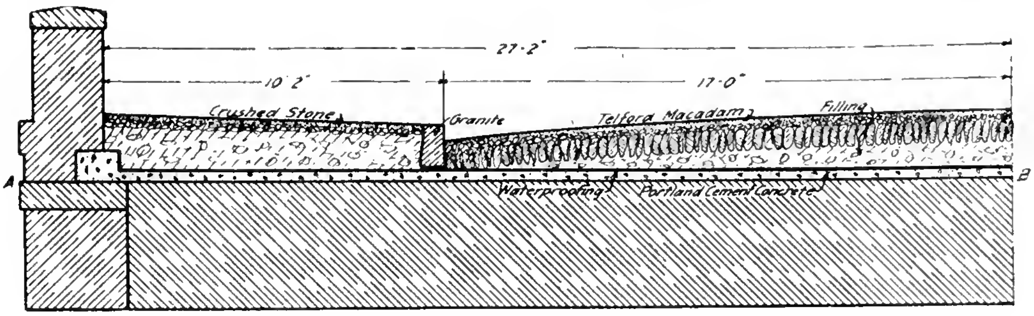
For a pavement of the Shuman type, described above, consisting of parallel strips laid edgewise, giving sections of some little length and considerable thickness, a reasonable distribution of the load will occur until the surfacing is reduced by wear so much that it should be replaced.

Distribution Due to Continuity

Under (b) an approximate analytical solution is possible, although such a solution should be used as a guide rather than as an accurate determination of the distribution.

The assumption commonly made in the design of railroad-bridge floors, that the rails distribute the load over three ties, may be properly made in the case of a highway bridge, but the tie loads resulting from a 50-ton trolley car thus distributed would be less than those coming from a 20-ton truck on two axles distributed through the floor planking, and hence would not ordinarily be the controlling factor in determining the size of a tie. It would seem proper, however, to test the strength of tie and planking for any given bridge by determining the stresses due to a derailed car, which case might readily be the controlling factor in the design.

The designer should bear in mind that the failure of the floor supporting surface would not result in the serious consequences that would follow the failure of the stringers or of the trusses and girders. Failures in the floor system occurring in well-designed bridges would be due to exceptionally heavy loads, in which case the burden of responsibility might well fall upon the transporting company.



Stone arch bridge with Telford macadam floor surface—Cost 39c per sq. ft.

Barrett Roof Guarantees

The Barrett Company, 17 Battery Place, New York, have given notice to contractors, architects, and other interested parties, that in future a twenty-year surety bond guaranty will be given without charge on all Barrett Specification Roofs of fifty squares, or more, in the United States and Canada, in towns of 25,000 or over, or any smaller place where the company's inspection service is available—provided the roof is laid by an approved roofing contractor and in strict accordance with the Barrett specifications. The experience of this company is that the Barrett roof will last for a minimum of twenty years without repairs and they are so convinced of this that they are willing to give a twenty-year guarantee. The bond will be issued by the United States Fidelity and Guarantee Company of Baltimore, one of the largest and best-known surety companies on the continent.

The Adaptability of Paving Materials

To Different Conditions and Localities—A Good Opportunity for Utilization of Local Materials—(Continued from May 17.)

By F. C. Pillsbury

Sand, in its natural condition is very seldom adapted to use on any kind of road surface unless used with some other material or as an auxiliary for the aid or relief of some kind of surface. Most sands, even those that are very fine, have qualities which make such use desirable. The fact has been well established that the particles of sand, when used in any bituminous or cement mixture for road purposes, should have a certain gradation from coarse to fine in order to obtain the greatest strength and other qualities necessary for superior endurance of the pavement. It has been found that even the loose sand of Cape Cod can be used without grading or the addition of other materials, except asphalt or asphaltic oil or tar, to give very practical results for country roads even when subject to considerable traffic and some heavy teaming, provided there is excellent drainage, particularly of the subsoil. This type of pavement, in the work done with the Cape Cod sands, is but an approximation of sheet asphalt, the difference being between extreme care taken to obtain sands of proper size, form and quality, and perfectly adapted asphalt for the sheet asphalt work, and the absence of any particular care except in the quality of the bitumen. Excellent results from sands are obtained when used in mixtures of other kinds, with gravel or broken stone. Experience has proved the advantage of using sand as a binder in laying water-bound macadam under certain conditions; also for stopping or arresting the ravelling of water-bound macadam. Its use with blanket or film coats of bitumen is well known. It frequently happens that bituminous macadam commences to break up under traffic from the effect of moisture and frost or moisture alone, and the prompt application of a layer of sand an inch or more in thickness over such spots prevents their breaking up. Fine loamy sands, quicksands, or others which absorb and hold moisture should be carefully avoided in the foundation, as their presence when too near the surface will lead to its destruction sooner or later. In such cases the same precautions and methods should be used in the foundations as when loam or clay is present. The sand-clay roads are also well known, but they are of little value in climates where frost action obtains. Sand is so various in its composition and formation and the results so various that unless its qualities are well known a careful study and analysis should be made before using in any important work. The use of sand not qualified for the desired purpose may lead to failure, particularly in high grade bituminous and Portland cement mixtures.

Gravel

Gravel occurs in such a multiplicity of forms and compositions that it is impossible in a paper of this kind to cover its use. Unless composed of rock which is too soft, or containing too much fine material, it is very valuable as a paving material and may be used in many different ways and for all kinds of traffic except that of extremely heavy weight. Its presence in the subgrade is desirable, and it may be used to advantage in most foundations, being better adapted for that purpose on extremely soft, moist soils, such as quicksand, loam, etc., than stones or telford. Its excellent qualities, however, frequently lead to its use where traffic conditions are too severe.

Clay, in its natural state, is of about as little value for road purposes as anything except loam. Its presence will generally lead to the failure of any surface that may be laid directly upon it, except in climates free from frost and surfaces subject to extremely light traffic. The writer considers that pavement a failure which does not carry the traffic for which it is designed, at a cost of construction and maintenance that is not at a minimum, although he realizes that there may be times when the financial condition of the community makes it necessary to adopt a surface that will not be satisfactory in those respects. The use of clay in the form of brick, while very successful from every point of view, under proper conditions, has failed sometimes for extrinsic reasons. It is essential that a brick pavement should be laid upon a stable base, especially in those climates subject to frost action. It should not be used under very heavy steel tire traffic. The writer has known of brick pavements being severely criticized when the fault did not lie in the brick, but when it was laid on imperfect foundation, or under unsuitable traffic conditions, or both. It makes an excellent surface for motor vehicles, and need not be slippery for horses. However, the greatest care should always be taken by means of testing to obtain brick of proper quality.

Stone

Stone, commonly speaking, is generally used in pavements by the following methods: in foundations, in water-bound macadam, bituminous macadam, bituminous and cement concrete and stone block pavements. There is frequently much waste of money in laying stone foundations, as they are often put in where unnecessary, or where clean, stony, or sandy gravel would not only serve the purpose, but to better advantage. This depends, of course, upon local conditions. The question is constantly arising between a choice of bituminous macadam or concrete and water-bound macadam. Almost always the choice depends upon the volume and nature of the traffic. Water-bound macadam will not carry any appreciable volume of motor vehicle traffic unless protected on the surface by some bituminous or other treatment, and even then the traffic must be light. Where there is much horse-drawn traffic it is sometimes better to surface with water-bound macadam, thus obtaining a surface which is generally less slippery, even if reconstruction is frequently necessary. There is much to be said as to a choice between bituminous macadam and bituminous concrete, but as with most other materials, much depends upon local conditions. There is a wide difference to be obtained in the quality of either of these pavements. This may be due to different methods, and is sure to follow variations in the quality of either the mineral aggregate or the bitumen. In the writer's opinion the local conditions should govern the choice and always the best materials available should be obtained. It is not necessary, beside being dangerous, to copy any set specifications covering these methods, and it is impracticable to lay down rules to be followed in making a choice. The natural materials that are most available should be taken and used to the best advantage according to their peculiar qualities. In many cases stone blocks might be used to much better advantage than they are, provided more pains were taken in laying the pavement, as well as in making the blocks. For those reasons many cities are now suffering from rough stone pavements. As stone pavements of good quality are probably the most permanent and will carry the heaviest traffic, they deserve more consideration than they have generally received. There is a difference of opinion as to the wearing qualities of certain kinds of stone.

Bitumen

Bituminous pavements provide for all kinds of traffic except the heaviest, by which is meant the extremely heavy traffic to be found in the large cities. Bituminous pavements have been the subject of so much discussion, and their uses are so familiar, that this paper will only mention in a brief way the more common methods, surface treatments and surface compositions, by either the penetration or mixing method. As stated under the use of broken stone, surface treatments of bituminous materials on water-bound macadam should only be used when the traffic is light, or where it is extremely desirable to have a good footing for horses, and in such cases where the traffic is at all heavy, it is better not to adopt the blanket coat method, but to use the film coat method, so-called. The choice between tars, oils and asphalts is often difficult to make. It is not possible to apply so-called heavy oils or tars except hot and in a blanket coat, as their consistencies are such that a considerable body of material is necessary to keep its place on the surface of the road. The lighter materials, which can be sprayed on cold, to cover the surface in much smaller quantity, will generally give more satisfactory and economical results. This is particularly true of so-called cut-backs or diluted asphalts. There are cases where tars for surface treatment seem to give better results than other materials, and the same may be said of nearly all materials used for surface treatments. Bituminous or other surface applications on macadam or gravel, or even on cement concrete, will never remain long enough to be economical where there is heavy teaming with steel-tired vehicles. Usually sufficient care is not taken in using bituminous materials in penetration or mixed work. Where proper care is taken in selecting the right kind of bitumen, and the right kind of mineral aggregate, and in the workmanship all the way through, bituminous pavements and surfaces should prove more economical than any others for all traffic of the present day, except for that which is very light or very heavy. It may not always be, however, the most desirable, partly on account of slipperiness which sometimes obtains, or local reasons. Its widely diversified qualities permit of its use under many different constructive conditions, and in pavements of very great difference in cost. It enables us to use sands, gravels, and rocks which would be practically worthless alone or with any other material than bitumen. Bituminous pavements have failed because of improper conditions in the base. Bituminous pavements do not fail any more than other kinds of pavements, when laid under suitable conditions, and composed of good bitumen, with the proper mineral aggregate.

The choice of materials also depends somewhat upon the treatment of the foundation. Moisture, with frost action, according to their degrees of intensity, with heavy traffic, usually require the most expensive and strongest pavements. So much depends upon drainage in such cases that where it is possible to obtain deep, open ditches on each side of the road, certain pavements will succeed without artificial foundation where without the side ditches or drains, even the strongest pavement would fail, as for instance, Portland cement concrete, or stone block on a concrete base. For the sake of comparison, consider climates where there is no frost action with that of New England. In countries where there is no frost action it would be extravagant to build the types of road required in New England or similar climates. On the other hand, it is impossible to build such light or thin pavements in New England as could successfully be built in those climates free from frost action, or comparatively so, and to have them withstand the weather conditions.

City Streets

City streets and the streets of the larger villages until recently were considered in a separate class from country roads, but during the past few years, and principally due to the ever increasing weight and volume of traffic, the main through roads and those connecting the larger centres of population, have come to be recognized as requiring practically the same treatment as city streets. Sometimes this treatment is more costly, as in the case of old highways where the foundations and drainage have to be taken care of, as well as the grades and alignments.

The greatest skill and wisdom is necessary in the reconstruction of old surfaces. There is much difference of opinion, and after all, the selection of materials in any case depends more than any other thing upon the knowledge and judgment of those making the selection. Advantage should be taken of the proximity of any natural materials that may possibly exist. This makes it necessary, if the wisest and most economical selections are to be made, to have a knowledge as wide as possible of all various types of surfaces, and all materials that are used for such purposes, including the materials in their natural state. It is with this in mind that the writer has ventured to discuss in a rudimentary way the simpler applications of the natural materials in their more common uses.

Coal Harbor Causeway at Vancouver

Providing the money can be spared from the various civic departments it is probable the long talked-of Coal Harbor causeway and entrance to Stanley Park, Vancouver, will be proceeded with this summer. The actual outlay involved is approximately $100,000, of which amount the Vancouver and District Joint Sewerage and Drainage Board will contribute $9,500 as its proportion of the sewer which is being laid in the sea wall. This work will form a link in the trunk sewer which reaches from Brockton Point through Stanley Park across Coal Harbor, and thence by tunnel along Park Road to English Bay, picking up the city's present sewers at that point, and ultimately reaching as far as Granville Street, along Beach Avenue, where it will intercept certain outlet sewers discharging at present into False Creek.

A Historical Sketch of the Grindstone Quarries of New Brunswick and Nova Scotia

As long as men have used steel tools there has been the need for grindstones and whetstones to give them an edge. This accounts for the fact that the quarrying and manufacture of these stones was one of the earliest branches of the stone business to be developed in this country. It is an industry, however, that is narrowly confined to the few localities where suitable deposits of sandstone are to be found. Canada has taken an important part in the production of grindstones and whetstones, for the reason that the sandstones of New Brunswick and Nova Scotia have been found particularly adaptable to this use. There is one fact that has made the production of Canadian grindstones among the most interesting of all quarrying operations in the world. The ledges of stone that are utilized for this purpose are on the coast line and extend out into the ocean. Much of the stone is actually extracted beneath the sea level.

One of the most important centres of the Canadian grindstone industry is at Stonehaven, Gloucester County, New Brunswick. The quarries of the Read Stone Company, which have been operated for sixty years are located there. The quarries are unique in their method of extracting the stone; the areas worked have been reclaimed from the sea by the building of dams. This has been no small undertaking. The dam around the present quarry which has just been finished, is over one-quarter of a mile long, and in all about a mile of dams has been built there. Anyone who has seen the Bay Chaleur in a storm will know that these dams must be very durable. They have been built chiefly of timber cribwork, filled with stone and heavily rip-rapped on the side exposed to the sea. The dams have been made water tight by the use of a clay puddle, pounded tight.

After the dam is built the water is pumped out and quarrying operations commence. The stone lies in horizontal sheets of varying thicknesses, the total depth of rock being about 25 feet. A steam channeller, steam and air drills are used as required and by the use of these and with powder and wedges the rock is quarried to the required size. It is then hoisted to the "dump" where the stonecutters take it and shape it round. From there, if it is not too thick for a single grindstone, it goes direct to the lathe to be finished. If the block is say two or three feet thick it is sent to the saws and cut to the required thickness. This applies to the larger stones, say 48 inches in diameter and larger. The smaller stones are split out of the irregular shaped pieces that come out along with the larger stones. The stones are cut round and shaped as a rough grindstone. In the olden days the grindstones were finished by hand by means of chisel and mallet. Now the rough grindstone is taken to the mill where the eye is drilled and the stone turned on a lathe in a very short time. Indeed, an expert turner will finish a small stone in five minutes. Many of the small grindstones, particularly the thinner ones, are made by sawing large blocks of stone into thin slabs, say 1½ to 2 inches thick. These slabs are then cut up into required sizes and the grindstone is finished on the lathe direct from the square slab.

The quarry is well equipped for handling stones. Three derricks are used at the quarry, two at the mill with a third in course of erection, and three at the wharf and station, while a travelling derrick operating under its own power and equipped with an orange peel bucket has been used for stripping purposes. One steam plant of 50 h.p. operates the hoisting machinery for the quarry derricks. Another of about the same capacity handles the pumping plant and the steam channeller. A 100 h.p. plant runs the mill machinery. This consists of an air compressor for the hammer drills used in the quarry, three gang saws, eight lathes, two scythe stone boxes, besides the necessary hoisting and pumping machinery, exhaust fans, etc. Water for the boilers is piped from a reservoir half a mile away.

The making of scythe stones is an interesting side line at this quarry. The block of stone is first sawed into slabs 1½ inches thick. These slabs are then broken under a special knife to pieces say 10 inches by 1½ inches by 1 inch. These pieces are then held under a weight to the surface of a revolving grinding bed. Sand and water are pumped on this bed and the stones are ground to a smooth surface.

In the early days at Stonehaven, the grindstones were quarried on the reefs at low tide, floated or hauled ashore, and finished by hand. These were perhaps the picturesque days of the industry, when men worked often to the waist in water, by day and by night as the tide suited. Stormy weather meant a partial stopping of the work. Shipments were made by scowing the stone out to schooners in the offing. At this time probably 300 men were employed. Later came machinery, and better shipping facilities, and now about 100 men are employed during the summer. Quarrying starts in May and ends in October. It is impossible to work when there is danger of the frost cracking the freshly quarried stone.

The grindstone industry of Canada had its beginning at the head of the Bay of Fundy, near Minudie, N. S., probably by the French, for local use, before the British occupation. Afterwards a British officer of distinction, Joseph Frederick Wallett DesBarres, later Governor of Prince Edward Island, secured a grant from the Crown, of Minudie and adjacent country, many miles in extent, and including the grindstone ledges at "The Joggins" as that part of the Bay shore was then called.

DesBarres later leased these ledges to his farmer tenants of Minudie, both French and English, who made grindstones by hand in a co-operative way. About 1815 Joseph Read and John Seaman, who came from Sackville, N. B., about 1808, leased farms from DesBarres' agent, acquired control of these ledges as shown by an old lease from the proprietors, and began regular shipments of grindstones to the United States in small vessels. The grindstone business has practically been in the hands of the Read and Seaman families ever since.

The business grew rapidly and was extended to other locations on the Bay of Fundy, both in Nova Scotia and in New Brunswick, the great tides of this bay baring the ledges of rock twice daily, allowing the rock to be excavated when the tide was low. With the rising tide boats were fastened over the loosened rock and large blocks were floated to high water level in convenient coves where, after the tide had fallen enough, workmen shaped the stones by hand into the grindstones of commerce. When a sufficient quantity had accumulated at any one place a vessel would come for them, grounding in a prepared berth near the grindstones (there were no wharves) and they would be hoisted on board by the quarrymen, no light task as many of these stones weighed over three tons. Later oxen and horses were used for hoisting.

Mill Construction and Fire Hazard

The Responsibility of the Architect and Engineer in Designing and Erecting Modern Buildings

By Franklin H. Wentworth*

Architects and builders are slowly entering into a new phase of their accountability. Just as the architect, whose primary impulse is that of the artist, has been compelled in the interest of his clients largely to master the technique of the builder, so both the architect and the builder are now being called upon to protect their clients in the matter of fire hazard. The enormous aggregate of the American fire waste, which contrasts so unfavorably with European prudence, is beginning to cripple and impoverish us as the natural resources of the country, once believed to be inexhaustible, are ceasing to respond to the demands of our habitual extravagance. The common notion that the insurance companies pay the cost of fires is gradually giving way to an intelligent understanding of the fact that they are merely the collectors and distributors of the fire tax. They must recover from the public the sums they pay out in losses, plus the cost of conducting their business and a reasonable interest upon their capital. If they could not do this there would be no business of underwriting, and sufferers from fire would be relieved only by direct assessment upon their more fortunate neighbors. It is not certain that a year or two of such direct assessment would not be an admirable educative experiment. At present the cost of the fire tax is merged with everything we eat and drink and wear, and the masses of the people are ignorant of the fact that they bear it.

This is no longer true of the manufacturing classes, however. The manufacturer now realizes that he pays a tax directly related in amount to the character of the building he occupies and the nature of his manufacturing processes; and that in addition to this he pays for the carelessness of all his neighbors. If he cannot shift this burden by passing it along to the users of his product, merged quietly in the selling price of his goods, then he must pay it out of his profits, which cripples him in the competitive struggle.

The manufacturer now clearly sees this and expects the architects and builders he may employ to see it also. If, after his factory is completed, he finds that points respecting the fire hazard have been ignored and that in consequence of some structural qualification, now too late to alter, he is doomed to pay a fire tax which forethought, with perhaps no additional expense, might have avoided, he may be considerably disturbed by it.

Experience in fire protection engineering suggests three points to be kept in mind in planning a factory:

1. There should be as little combustible material as possible used in its construction and equipment.

2. Each floor should be absolutely cut off from every other floor and each section from every other section, so that fire may not communicate.

3. Every part of the factory should be equipped with fire extinguishing apparatus.

It is obvious that a factory of reinforced concrete will present certain advantages respecting the fire hazard over the slow-burning or "mill construction" type; although the latter is preferred by many manufacturers as presenting more convenient surfaces for the attachment of pulleys, shafting and machinery. Slow-burning construction is not undesirable if properly safeguarded and protected.

Advantages of Reinforced Concrete

The advantages of the use of reinforced concrete appear when we consider that with such construction every floor may, by avoidance of vertical openings through it, be made practically a fire wall. The floors being incombustible, a fire in any storey may be ordinarily confined to that storey. In the old type of factory, having open elevator shafts and belt openings from floor to floor, fire quickly ran from storey to storey, and was soon beyond the control of the firemen. It is essential that in all factories, of whatever type of construction, stairs, elevator and belts be placed in fireproof enclosures with openings to each floor protected by fire doors or shutters. If in addition to the omission of all vertical openings provision be made to drain the floors through scuppers set into the outside walls, the possibility of water damage to goods or materials on floors below is much lessened. The standard form of brick or concrete stair and elevator tower may also serve this purpose. If the building as a whole is of fire-resistive material, it naturally presents less fuel upon which a fire may feed, and there is therefore less chance of a serious fire if for any reason the extinguishing agents are temporarily disabled. It must be remembered, however, that buildings are often destroyed by the burning of their combustible contents, and in all types of mills and factories the floor area should be kept down to the minimum limit consistent with convenience and economic operation of the plant. These areas should be divided by fire walls, all openings in which should be protected by standard self-closing fire doors. These precautions minimize the danger of a rapid spread of fire horizontally. All mill-constructed buildings, if of large area, should be divided into sections by special fire walls extending above the roof and out beyond the walls of either side.

Steel Window Sash

Whether exposed to possible fire from adjacent buildings or not, there should be no wooden frames or trim about the windows. Window frames should be of metal fitted with sashes of wired glass, for under strong draught fire frequently creeps up outside from storey to storey by means of the windows, con-

* Of the National Fire Protection Association in Architect and Engineer.

suming the wood trim and igniting contents of the building on each floor. Metal window frames are now so constructed that they will stand very considerable exposure to fire without buckling or releasing the glass, and, their liberal use in all varieties of buildings is greatly to be desired. The sashes may be operated as conveniently as those of any other window.

It will be observed that all the suggestions made for fire walls, stair and elevator enclosures and window openings are as applicable to buildings of mill or slow-burning construction as to those of concrete.

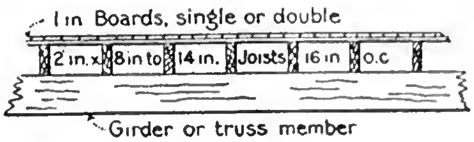


Fig. 1

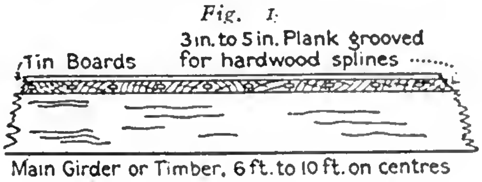

Fig. 2

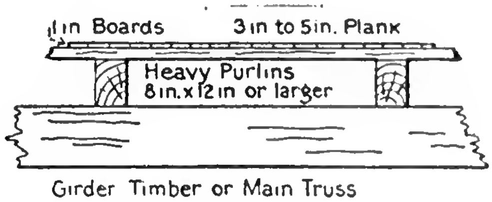

Fig. 3

Desirable and Undesirable Forms of Construction—Fig. 1, Undesirable because of the large amount of fire exposed wood surface. Figs. 2 and 3 Desirable Forms.

They should be followed, as far as possible, in all factory construction and in mercantile buildings as well.

In certain buildings of mill construction, carrying stocks of excessive weight, it has been a common practice to make the main beams of two pieces of timber side by side, bolted together. An air space between the pieces was formerly advocated in behalf of better seasoning and possible avoidance of dry rot. Experience has demonstrated, however, that this space not only reduces the resistance of the beams to fire by offering almost double the wooden surface to its attack, but that in case of fire getting started the space between the beams holds it for a long time and prevents its extinction. It is abvious that neither automatic sprinklers nor ordinary hose-streams can successfully reach fire lurking in such narrow alleys. Such construction should be avoided.

Slow-Burning Mill Construction

Mill or slow-burning construction presents its own inherent problems. Enough wood must be used to insure strength and stability, but superfluous wood should be avoided. It matters very much as to just how the quantity of timber used may be disposed. The guiding thought of the architects should be to present to the fire attack the least practicable amount of wood surface.

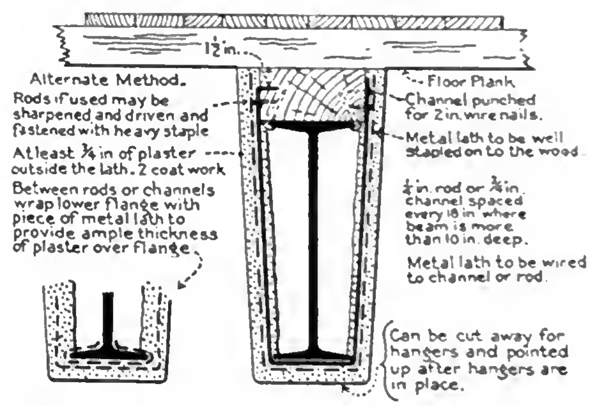
For example, a mill planned with heavy beams eight to eleven feet on centers of continuous spans from wall to post or post to post of from twenty to twenty-five feet is infinitely more desirable than one of miscalled mill construction having longitudinal girders resting upon posts on which girders are placed four feet or less on centers. The latter construction not only adds to the exposed wood surfaces which may be attacked by fire, but the disposal of the timbers obstructs the action of sprinklers and prevents the sweeping of hose streams from one side of the mill to the other.

No architect with the consciousness of the fire hazard will ever plan for either manufacturing or mercantile occupancy those undesirable fire boxes known as "light-joisted" buildings. Light joists or rafters two or three inches in width, spaced from ten to sixteen inches on centers, ignite and burn like kindling. Their numerous corners furnish projections for easy ignition. The menace of such construction may be aggravated by sheathing under the joists. This provides a series of wooden cells, pervaded with concealed spaces in which fire may riot and lodge and dodge extinguishment until the floor or roof is burned through. By the same token partitions of light wood should be avoided.

Timber posts offer greater resistance to fire than wrought-iron, steel, or cast-iron pillars, and are preferable in mill construction. Experiments show that sound timber posts of the proportion customarily used in mill work yield by direct crushing and not by crippling, the strength being directly as the area of cross section of the smallest part. The columns yielded at about four thousand five hundred pounds per square inch, confirming the general practice of allowing six hundred pounds per square inch as a safe load. Square columns are therefore one-fourth stronger than round ones of the same diameter, and do not encroach to any appreciable extent upon the floor space. It is the general practice to bore a hole one and one-half inches in diameter along the axis of the column to reduce checking. This should be done in any event, for if posts of unseasoned wood should by any chance be painted, varnished or filled, they are liable to be attacked by dry rot if unventilated.

Case Steel Beams

In machine shops and other plants requiring exceptionally heavy floor construction above the ground level, steel beams are frequently called into service.



Suggestion for Fireproofing Steel Beams

Fig. 4

With these, if wide spacings of from seven to twelve and one-half feet are maintained, the advantages of standard mill construction are not forfeited if the steel members are suitably fire-proofed. Desired floor stiffness between beams may be secured by making floors of two-inch joists on edge spiked together, the thickness of the floors varying with the loads and span from five to eight inches or more. This floor being practically a single unit, provision must be made for longitudinal contraction by making a continuous joint in the under flooring at intervals, with, of course, arrangement for tying the building together. One thickness of hard, close-grained floor boards laid over planks with two layers of resin-sized paper between is a good floor. A method that is growing in favor in high-class factories is to lay a board flooring diagonally or at right angles to the plank, and over that a top floor of birch or maple laid lengthwise. This intermediate floor gives great resistance to the lateral strain or vibration. It can be made of cheap lumber and in many factories is well worth the additional cost.

It is obvious that where steel beams or posts are used they should be properly protected. As steel or wrought iron, when heated, will fail by buckling or bending before an equivalent beam or post of wood will be dangerously affected, it is of importance that steel members essential to the stability of the structure be fireproofed; otherwise a fire in a lower storey may bring down in wreck everything above it. Where steel beams support wooden floors they must be fireproofed if they are to resist fire as well as the floors. The accompanying cut gives in detail an inexpensive method of protecting steel beams, and this is also applicable to wrought iron or steel columns. A more substantial method is usually advisable for the latter, however, and protection against mechanical injury near the floor should be provided.

Special Fire Hazards

There is another matter which should never escape consideration in building a factory. This is the special fire hazards incident to the character of the factory product. The picker room of the cotton mill is a luminous example. Here fire frequently occurs from foreign substances striking the pickers and igniting, by the accompanying spark, the inflammable cotton. Sufficient statistics are now available on almost every well known manufacturing process to indicate just what elements in such process are especially susceptible to fire. Bulwarked by this knowledge, it is prudent to segregate from the principal values of the factory all special processes demonstrated by experience to be especially hazardous. This does not mean that such processes must be carried on in separate buildings at the cost of traveling time and inconvenience. The problem of segregation can now be met without shifting the process out of its logical place in the routine of manufacture. In a fireproofed factory only a separate room, or at best a separate floor is needed. The manufacturer who, once when he had a fire in some room where volatile oils, for example, were used, commonly lost half his plant, or at any rate so drenched his premises with water as to make a fortnight's suspension necessary, can now, if he likes, so dispose that hazard as to have a fire every other day without disturbing the other parts of the factory. The modern fireproof room equipped with automatic sprinklers, having a slightly pitched floor and scuppers at the walls, can be flooded for fire extinguishment without a drop coming through below. The water runs as harmlessly from it as from the deck of a ship.

In mill construction it is easy to fireproof the floors and ceilings of any room in which quick, flashy fires are liable to occur. In the picker rooms of cotton mills a similar protection to that above suggested for steel beams is often used, the metal lath being applied directly to the under side of the planking and around the beams.

With the general outline so far given for his guidance the architect or builder will have before him the main points in building construction for the protection of his clients respecting the fire hazard. A consciousness and proper consideration of them may save many dollars in insurance premiums, and at the same time provide an attractive risk that with suitable further protection can hardly under any circumstances prove a total loss. There remains, however, after observance of the points of construction, consideration of the fire extinguishing agencies. These may appear to be outside the proper province of the architect, but his knowledge of their character and importance will help vastly in the convenience of their installation, and a little preliminary thought about them may save much tearing out and minor reconstruction. The architects who led the van in providing shafts, channels and runways for electric wires before such conveniences were demanded by inspectors, saved their clients an incalculable amount of annoyance.

Automatic Sprinklers

It is obvious to any well-informed person that the manufacturer who today builds without provision for automatic sprinkler protection almost wilfully endangers not only his plant, but the lives of his employees. It is not sufficient that the building be fireproofed. Fireproofed is but a relative term. Buildings of fireproof construction are often wrecked and ruined by the burning of their contents. Provision must be made for the extinguishment of a fire the moment it starts. Automatic sprinklers will do this if properly installed with an adequate water supply. Where a sprinkler system fails it will in almost every case be found to have been somehow neglected previous to the fire. Automatic sprinklers, with their increasing adoption, have almost eliminated a kind of fire which used to be especially destructive; namely, explosions of gaseous products generated by previous slow and imperfect combustion in stock or goods. Automatic sprinkler protection should, therefore, be considered imperative and intelligently provided for, and all concealed spaces or places difficult to protect properly by such a system should be studiously avoided. Vast inconvenience may be obviated by architects and builders giving thought to this point. Ample water supply for the average factory demands two independent sources. One should be by gravity and of sufficient volume and pressure to afford a good supply until the secondary supply can be drawn upon. Pumps, tanks and other details are not within the scope of this article; nor are fire pails and hand chemical extinguishers which need no advance provision, being placed in any convenient or desirable location.

Stand Pipes for High Buildings

The architect should give thought to a stand-pipe system, however, in factories of three storeys or higher. They are invaluable for carrying water for hose streams to upper floors, thus making unnecessary the handling of hose on ladders or on stairways, which is difficult and often entails costly delay. They should ordinarily be placed in the main stair towers, or at any rate on the opposite side of the wall from the rooms or buildings they are designed to protect. Where buildings are near enough to each other for the roofs to afford vantage points for use of hose streams, stand-pipes should be extended to supply roof hydrants.

In factories having loose combustible stock in process an equipment of small linen hose on each floor is invaluable. It is best to supply this from an independent system of small pipes. It may then be available in case water is temporarily shut off the sprinklers, or in final extinguishment of smouldering sparks after sprinklers have been shut off to save excessive water drainage.

There are many other details to be considered in properly protecting a factory from fire, but they are details in which the fire protection engineer is not dependent upon the provision or co-operation of the architect. If the points touched upon in this article have been made clear enough to enable the architect or builder to gain a general survey of the responsibilities his clients are coming to impose upon him, the absence of technical instruction will not impair its value.

The Utilization of Pulverized Earth in Asphaltic Mixtures

By Francis P. Smith*

[This paper is a discussion of Mr. Pillsbury's paper on "The Adaptability of Road Paving Materials to Different Conditions and Localities," which is concluded in this issue of the Contract Record.]

Mr. Pillsbury, in his paper on The Adaptability of Road Paving Materials to Different Conditions and Localities, discusses the fact that through changes in the process of manufacture and possibly in cementing mediums used many materials which are not now considered advisable for paving purposes may prove to be very valuable.

This is particularly true as regards broken stone or sand in which the particles are covered or closely associated with fine material of a more or less cementitious nature, such as clay or loam. Up to very recently such materials have been regarded as being unsuitable for paving purposes, owing to the fact that during their passage through the drier the finely divided cementitious particles have a tendency to form loosely coherent balls or attach themselves more or less firmly to the larger particles. When the hot mineral aggregate is mixed with bituminous cementing material the attrition of the mass in the ordinary type of mixer is not sufficient to remove the coating which has been formed upon the larger grains or to break up the balls of fine material. The bitumen, therefore, does not come in sufficiently intimate contact with the true surface of the larger particles to form a permanently adherent coating and only the outside surfaces of the fine mineral aggregate which has formed into balls receives a bituminous coating. Under the stress of traffic and climatic changes these balls are broken up and the interior of them, composed of loose pulverized material, is removed by the action of traffic, leaving pits in the surface in which water will accumulate. The coating of fine material, which to a certain extent has been formed on the surface of the larger particles, also becomes detached, carrying with it the coating of bitumen, thus loosening the bond of these particles and permitting them to ravel out.

It has been known for a long time that clay, owing to its affinity for bitumen, is a very valuable filler or constituent for pavements of the sheet asphalt type. It has heretofore been impossible to employ a sand containing appreciable quantities of clay for the reasons above stated and the use of ground clay as a filler to be added to the mixture in place of Portland cement or limestone dust has been impracticable owing to the tendency of the clay, even after being dried and ground, to absorb moisture and form into balls.

Recent developments in machinery for the manufacture of bituminous pavements have, however, rendered it possible to use materials containing a large percentage of clay. This is accomplished by subjecting the dried and heated aggregate to the action of a pulverizer in which the attrition of the particles is sufficient to break up any balls which may have been formed by the passage of the mineral aggregate through the drier and also to thoroughly clean the larger particles from any adhering clay or powder. By the action of the pulverizer the amount of 200-mesh material can be increased up to almost any desired point. The pulverizing action naturally exerts its greatest force upon the softer particles of the aggregate and the fine material formed is therefore largely derived from the softer ingredients and thus produces a more desirable dust or filler than can be obtained from pure quartz. Heretofore one of the serious problems connected with the paving industry, more especially where the traffic to which the pavement was to be subjected was extremely heavy, was the selection of sands which, when combined, would have the different sized particles present in the proper amounts to form a dense and compact pavement. In many cases it has been extremely difficult to secure such sands, more especially those which contain the requisite amounts of 100-mesh and 80-mesh particles. With the pulverizer, practically any amount of these fine particles can be produced from a sand which is naturally deficient in them. Where sands are naturally deficient in coarse particles of the 10, 20 and 30 mesh sizes they tend to make a pavement which is lacking in stability and is susceptible to displacement under traffic.

To a very large extent this instability of the mineral aggregate can be compensated for by an increase in the amounts of the finer particles. This is illustrated extremely well in French rock asphalt pavements, which contain practically no coarse particles and are largely composed of 200, 100 and 80-mesh particles. The action of the pulverizer, therefore, appears to eliminate a number of the difficulties attendant upon the use of former types of machinery for the manufacture of bituminous pavements.

Limit of Fine Material

This does not mean, however, that the action of the pulverizer should be permitted without proper supervision and regulation. A standard sheet asphalt pavement for heavy traffic usually contains a total of from 30 to 40 per cent. of material passing the 200, 100 and 80-mesh sieves. An increase of this fine material beyond a certain point results in increased instability of the pavement. After the critical point has been reached stability again increases. The amount of bitumen to be added to the mixture also depends

* Before the American Good Roads Congress, Pittsburg

upon the percentage of fine particles. As these are increased the surface area to be coated with bitumen increases and naturally calls for an increase in bitumen. Where the fine particles form the bulk of the mineral aggregate, it is often desirable to reduce the indicated bitumen contents caused by the increased surface area by thinning the consistency of the bitumen and making the coating on each grain thinner than in the normal sheet asphalt mixture. This can safely be done where the particles of the mineral aggregate (as in the case of French rock pavements) pack together very firmly when dry, and when so packed are extremely stable. Another difficulty is also met with in this connection and that is the tendency of a hot aggregate, containing a large percentage of fine material, to seggregate in the storage bins, thus making it difficult to draw from them a mineral aggregate of uniform mesh composition. This, however, is a mechanical difficulty which is not very hard to provide for. Mixtures containing large percentages of fine particles also require more thorough mixing than do those in which the proportion of fine particles is lower.

In asphalt block manufacture the bitumen used must necessarily be very non-susceptible to changes in temperature and is therefore relatively low in cementing value and fluidity. This makes it more difficult to thoroughly coat the particles with a firmly adherent film of bitumen and it has heretofore been absolutely necessary to use only clean, fresh broken stone in which the larger particles are free from adhering stone dust. It is probable that if a successful device can be installed which will clean the particles after their passage through the drying drums, stone which has not been freshly crushed may be successfully employed.

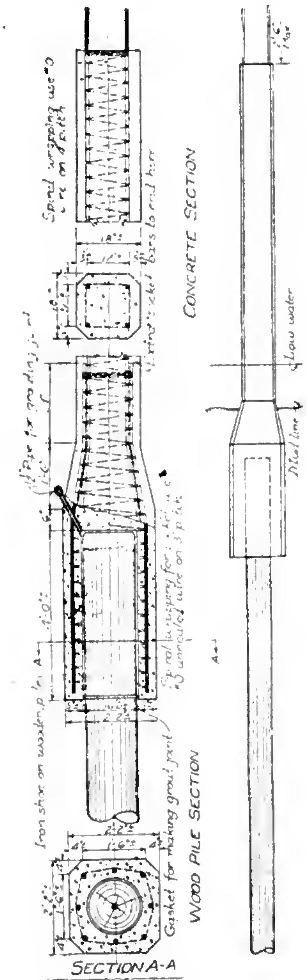
Experience covering widely different climatic and subsoil conditions is essential before any final judgment of the value of particular types of bituminous construction can be made, and what is one man's meat in one locality may well prove to be another man's poison in other localities.

A Combined Wood and Concrete Pile

COMBINATION piles, designed to resist decay and to be sufficiently strong and yet cheaper, it is claimed, than precast concrete piles, are now made with the lower portion of wood and the upper part of concrete. These piles are specially adapted for bridge or wharf construction or work on piers in water or low swampy regions. Wooden piles, while they will last for a long period if completely submerged, deteriorate rapidly if exposed to the air with sufficient moisture. Concrete piles are an ideal form of construction in so far as decay is concerned; they are also fireproof, but their disadvantage is their limited length due to their great weight and small cross section. They are initially more expensive than wood piles, and in places where the lower part is to be completely submerged, the combination pile should prove economical, in that is is cheaper and yet quite as permanent. Wood submerged or sunk in mud will last indefinitely.

The new pile is constructed of reinforced concrete, molded on the ground in either steel or wood forms prior to driving. One end is furnished with a socket for superimposing upon a wooden pile, the idea being to use the wooden pile in the ground below the mud line and place upon it the concrete socket pile.

Soundings are first made in the usual manner and the length of the wooden pile computed so that its top, when driven, will be a foot or two below the mud line. The pile is then driven to within a short distance of the water line. A collar of burlap or other material is placed around the pile at a point near where the end of the socket will come and the concrete socket pile is then placed over the wooden one. The socket pile is held up about six inches while all the space in the socket not occupied by the end of the wood pile is filled with grout through a small pipe fitted in the socket for that purpose and the pipe capped. The socket pile is then dropped into place and the heavy pressure forces the grout into all voids. The combined pile is then driven home.



Details of a Combination Wood and Concrete Pile.

The most severe test proved without doubt that the combination pile can be depended upon for at least as great efficiency as the ordinary type of concrete pile. It is also being used with success for repair work on many existing structures.

The Turbine Equipment Company, Limited, Toronto, have secured a contract from the Nova Scotia Steel & Coal Company for a 1,000 h.p. De Laval marine type steam turbine for one of the new boats being built by that company. The speed of the propeller is to be 80 r.p.m. and a set of double helical reduction gears are to be provided to reduce proportionately the speed of the turbine. The Turbine Equipment Company are also supplying the condensing equipment, bilge and boiler feed pumps.

Points to Bear in Mind in Laying Out Large Concrete Mixing Plants

Reinforced concrete is occupying such a large field in construction work of big dimensions that the question of distributing the concrete from a central mixing plant to remote parts of the work, is an item that involves considerable time and expense, and the plant and mechanical equipment necessary is very often expensive and occupies considerable space. Thus a

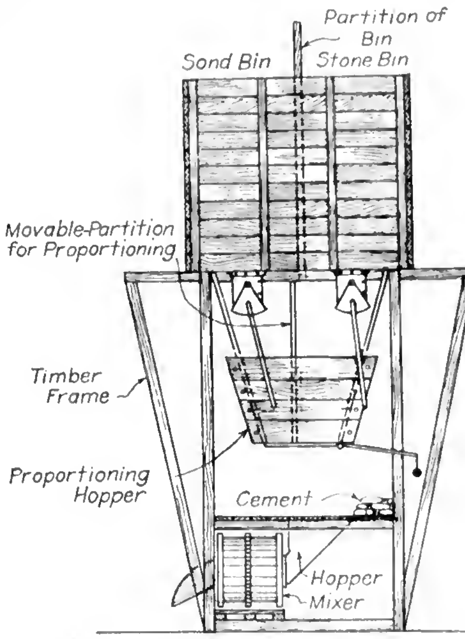


Fig. 1.—A convenient arrangement for storage bins and proportioning hopper.

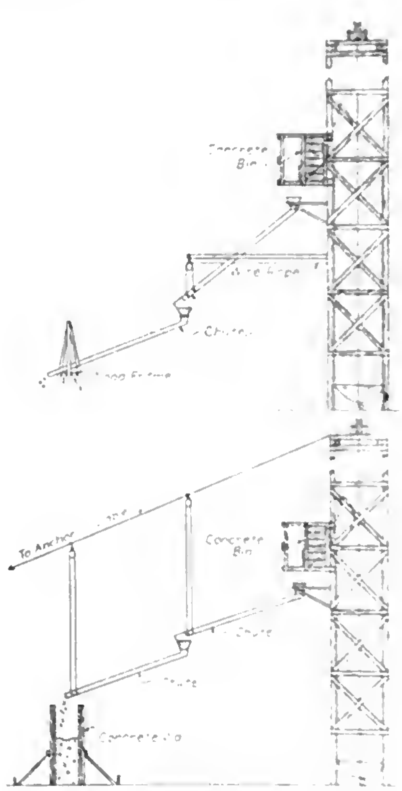
mechanical plant for any large structure should be carefully planned and laid out.

Concrete handling equipment may be divided into two general classes—standard and special equipment. The former consists of such machinery as a contractor may keep on band and use on any ordinary job, such as: standard mixers, wheelbarrows, cement buggies, hoists, etc., while the special equipment touches items not, as yet, usually included in a general contractor's equipment, but which must be built to suit the requirements of the work on hand. Such equipment might consist of standard cars and tracks, cable ways, storage bins, concrete chutes, etc. Special equipment, unless it can be used on subsequent jobs may not pay for itself on a single contract, as the extra cost would more than overbalance the saving in labor and eat up most of the profits. This must always be carefully figured out by the contractor beforehand.

Positive rules cannot be laid down for the selection of a plant for any and all types of construction, yet it is possible to fix a few general rules for guidance in fixing the type. Insofar as a mechanical plant is a substitute for labor, no more should be expended on it than would yield good returns. This is an item which has too often been overdone; too much has been expended for equipment. This should be specially guarded against, if it is at all uncertain whether the equipment will be used on any further contracts. Jobs vary so much that the distributing equipment for one may not be at all advisable for another. In many cases the difference in efficiency between the standard plant already in the contractor's possession and a special one which might be erected for a particular job, is not sufficient to warrant the extra outlay, since it must be charged directly against the one job. In whatever case, the plant efficiency is going to be gauged, both by its layout and operation.

A continuous automatic system of mixing and distributing concrete through simple standard conveyors that can be maintained and operated in any position, easily shifted and offering very little obstruction, is the thing desired. The figures herewith show a few common methods of handling and storing materials for a concrete job.

The advisability of a standard mixing machine is now practically universally conceded. It offers a very material saving in manual labor, produces a better and more uniform mix, and is productive of greater speed in construction. An efficient concrete plant is one in which all departments are kept going. Since everything is based on the supply of concrete, which may



Figs. 2 and 3.—Showing methods of supporting chutes.

be called the pace-maker, it should be as uniform and steady in its output as possible. For this reason it is important to adopt a mechanical mixer.

Mixing may be considered from three points, namely: charging, mixing and discharging. In charging the mixer a limit is set by the physical laws governing the flow of materials from one vessel into another, and the maximum efficiency for this operation is attained in proportion as this limit is more or less nearly approached. This time may be substantially cut by using carts holding about six cubic feet instead of the ordinary three-foot wheelbarrows, or by using a charging car; or, better still, by so arranging the mixer that the materials may be stored above it and be discharged into the hopper by the force of gravity, as shown in Fig. 1. This is perhaps the most economical and nearly ideal method.

Thorough mixing is quickly accomplished in any modern mixer, 30 to 45 seconds being ordinarily long enough for the operation, although for best results it perhaps ought to stay in the mixer one minute. Modern mixers are driven at from 16 to 20 revolutions per minute, and at each revolution the material makes four or more complete turns. For quick and uniform mixing, water should first be fed into the mixer in uniform amount. If the water is introduced before the material, it prevents the latter from adhering to the sides of the mixer.

To discharge the mixer requires from 10 to 20 seconds, depending upon the size of the mixer and the size and consistency of the batch. The all-important factor is the speed of the drum, a difference of 5 r.p.m. being enough to make a considerable variation in the time of discharge.

The arrangement of the plant, of course, depends on local conditions, the extent and nature of the work,

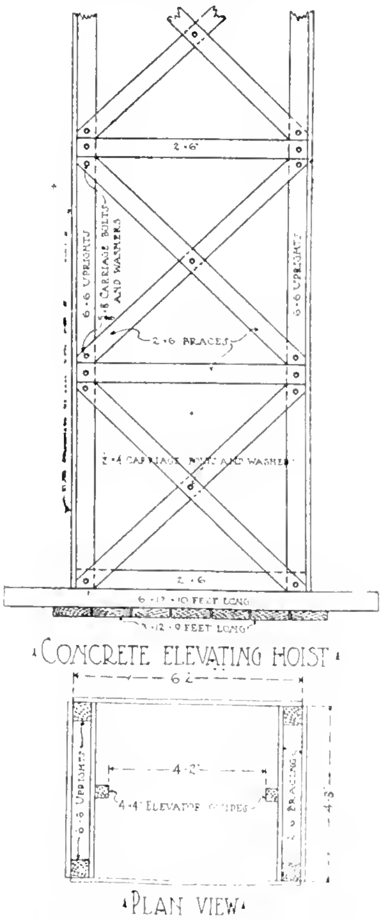


Fig. 4.—Details for a hoisting tower.

the contour of the ground, the accessibility of the site for delivery of material, and the available space for the plant. The material may come to the work either in wagons or cars and may be either dumped in piles convenient to the mixer or placed in storage bins. Cement is usually stored in a shed or placed under some sort of suitable cover. In many cases no special provision is needed for storing materials, but in others the handling of materials economically warrants some investment in storage bins. Fig. 1, already referred to, is an ingenious arrangement of a double apartment bin with sand in one side and stone in the other, so arranged that they discharge directly into a proportioning hopper below and from there into the mixer. It is generally advantageous to place the mixer below the level of the ground on which the material is placed. This is often done by setting it in the basement, if it is a building contract, or outside of the foundation in

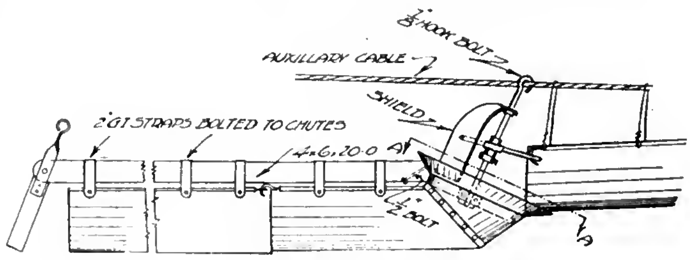

Fig. 5.—Details showing a chute joint, and method of suspension.

a pit excavated for the purpose. This facilitates charging. A special arrangement, a storage bin with a proportioning hopper, can be built, and by adjusting the movable partition, any proportion of aggregates may be had. In cases where the material is brought in by rail and the switch is at all distant from the mixing plant, it may prove profitable to carry the material to the plant on small side-dump cars, which can be elevated sufficiently to discharge directly into the proportioning hoppers or storage bins, the cars returning to the switch by gravity.

The position of the mixing plant depends on two factors—the location of the raw products and the distributing of the concrete. When a large mixer is once set up it should, if possible, be in a position to handle the entire job without shifting. This necessitates the use of chutes (see Figs. 2 and 3)to carry the concrete to different parts of the work. In some plants the concrete is carried from tower to tower by chutes, and re-elevated at each tower, making the use of one plant only necessary. The separation of the coarse aggregates and the mortar, however, is a grave danger in such plants, and should be watched carefully.

The tower and chute method of distribution, which has now generally supplanted the older method of wheeling the concrete in buggies to the forms, is shown in Figs. 2 and 3. The tower must be of suitable construction, rising from the mixer base to a sufficient elevation. Fig. 4 shows the details of a standard wooden tower such as is generally employed. It is built of 6 in. x 6 in. x 18 ft. uprights and 4 in. x 4 in. elevator guides, 2 in. x 6 in. x 12 in. fish plates, 2 in. x 6 in. braces, properly bolted. Further details are shown in the drawings. The elevator is usually driven by the same engine that runs the mixer.

Trip blocks and a receiving hopper are arranged to be adjustable to any height to suit the requirements of the work. The elevator, on reaching the block, trips and dumps into the receiving hopper, which usually has two discharge spouts, one near the bottom of each side. Each spout is fitted with a controlling gate and concrete may be discharged through either set of chutes at the will of an operator stationed on the tower. Figs. 2 and 3 show the most convenient form of supporting chutes—the cable from the top of the tower is run out and anchored and the spout lengths are suspended from this cable. Another method of supporting them is by derricks or by a boom supported by cables from the tower with a special A frame at the end mounted on wheels, which allows it to be moved about conveniently. Fig. 5 shows a joint between two successive lengths of chutes and the means of suspending the chutes from the catenary. The most convenient slope for the chutes is 1 vertical to 4 horizontal. Any excessive slope soon wears the steel chutes out, especially at the joints. The slope should gradually increase as the distance from the tower increases.

The volume of concrete construction throughout the country is becoming so great that it warrants the use of an extensive amount of standard and special equipment. Most of these items of machinery are used to profitable advantage, and with a little more study and experience, what is now special equipment may soon be called standard and be included in the general contractor's list of machinery.

The Effect of the War on the Price of Glass

The effect of the war on the price of glass, however the circumstances may be explained, has been that the year 1915 saw the lowest prices in the history of the glass industry. The situation indeed was so bad that three of the largest manufacturers in the United States were closed down, as a result, as one of the survivors recently put it, of "ruinous competition." The members of this trade are now naturally asking themselves, why? What do we gain by a price-cutting campaign that prevents even the strongest firms from making a living profit? There is little evidence that any more glass is sold at the cut price than if a fair rate were maintained. Would it not be better to get together and arrange a proper working basis on which a living profit could be made by whoever gets the business? Would it not be better to make the competition one of business-getting ability rather than of mere underselling?

A couple of interesting letters touching upon this situation have just come to hand. A solution of the difficulty has been suggested in a letter by Mr. Bradshaw, of the H. M. Hooker Company, to Mr. Cowan, manager of the Luxfer Prism Company, Toronto. Mr. Cowan passes the letter along to us with his own comment. Both letters are reproduced below:—

Toronto, May 15th, 1916.

Editor, Contract Record:—

I enclose a letter from one of the leading leaded glass manufacturers of Chicago, who is also an active member of the Ornamental Glass Manufacturers' Association of United States and Canada, and believe that he is striking a note which needs to be struck hard in our branch as well as in several other branches of the building trade. It is not for me to say that the different members of the glass business should unionize, but I do know, and every one of us knows, that something should be done to lift the business out of the slough of despond which it is in to-day and has been in for a long time past. This applies not only to the glass business, but also to certain sections of the iron business, with which we come in contact. Although we have secured certain contracts at figures which we consider quite low enough, we have been beaten out on others by figures 20 to 25 per cent. lower.

I feel satisfied that for the general benefit of the trade it would be wise if all the different members could wake up to the extent that we could get together and decide that prices be put on a basis where they would show a margin of profit. Each apparently at the present time is figuring to beat the other on a price basis. This simply has the effect that each is losing his money.

I do not believe that there is any object in keeping this sort of information under our hats, as it should be public property. Everybody in the business knows they are losing money, and the sooner we all wake up and get together the better.

I send this as a member of the Executive of the National Ornamental Glass Manufacturers' Association, and if you think it wise to publish this communication I will be very pleased not only to have this done but to co-operate in any way to improve conditions in the trade.

Yours truly,

Luxfer Prism Company, Limited.

Per W. Cowan, Manager

W. Cowan,
100 King Street West,
Toronto, Canada.

Dear Sir:—

It seems to be the universal consensus of opinion among the art glass trade, that something heroic must soon be done to put the profession on a paying basis, yet, no one has come forth with a solution of the acknowledged difficult problem. We are all fully aware that there are many defects to be cured, but what we are all interested in is the cure. We write about the abuses which are perpetuated, we criticize and sometimes condemn the other fellow, but fail absolutely to apply the cause to ourselves, and, as a possible remedy, may I suggest this one thought. **Unionize.**

We are not equally situated, we are not all sharing the same responsibilities, nor are we working under the same conditions, which make it very difficult to establish or maintain a uniform price, such as is being done among kindred trades. You see other lines of business advancing by leaps and bounds, and profits piling higher and higher, while your bank account, Mr. Art Glass Man, is most likely growing smaller and smaller. There is a reason. What do you think of a uniform scale of wages, and a standard form of working conditions? Would it not guide us in the direction which would result in the general up-lift of our business?

I am firmly of the opinion that a union of principles, backed up and regulated by a properly organized union of labor whereby we are all paying the same scale of wages, and working in harmony, will be the proper thing. What do you think about it, my Art Glass brother? This matter may come before our next convention, and an opinion from you at your earliest convenience, setting forth your views, so that we may be guided intelligently, in our future deliberations, will be highly appreciated at this time.

The art glass workers have federated with the Brotherhood of Painters, Decorators, and Paper Hangers of America. What are we going to do?

Sincerely yours,

G. N. Bradshaw

The new Dominion Observatory building on Little Saanich Mountain, near Victoria, is rapidly nearing completion. The dome to house the largest telescope in the world reached Victoria on March 22nd from the Warner & Swasey Works at Cleveland, the sections occupying eight cars and weighing 125 tons. With the dome came a quantity of special erecting machinery to aid in putting the steel work together rapidly.

Moulding Reinforced Concrete Lighting Standards by a Centrifugal Process

CONCRETE poles for carrying light and power, as well as serving for lighting standards, are quite common in the city of Toronto, which has perhaps the largest number of concrete poles of any city on this continent. The re-inforced concrete lighting standard is becoming recognized as superior to those of bronze, wood, cast iron, pressed steel, or copper covered. Not only in the first cost is the concrete designed lower, but in the matter of maintenance also. A new improved type of re-inforced concrete standard which has been manufactured for some southern California cities by a centrifugal process, is described in Concrete by L. R. W. Allison, of Newark, N. J. This process of moulding offers some interesting features of operation. The method of formation indicates, both in theory and practice, a logical and effectual means of production, at the same time showing reduction in cost factors that tend to enhance the extensive employment of these standards for all practical and economical purposes.

The fundamental principle involved in centrifugal concrete manufacture is that of effecting proper compression by centrifugal action. As is evident, in revolving a wet mix by this process the area of greatest compression is at the point of greatest radius. This affords the desired density in actions where it is most needed, resulting in a product, with cored center, of great structural strength and stability.

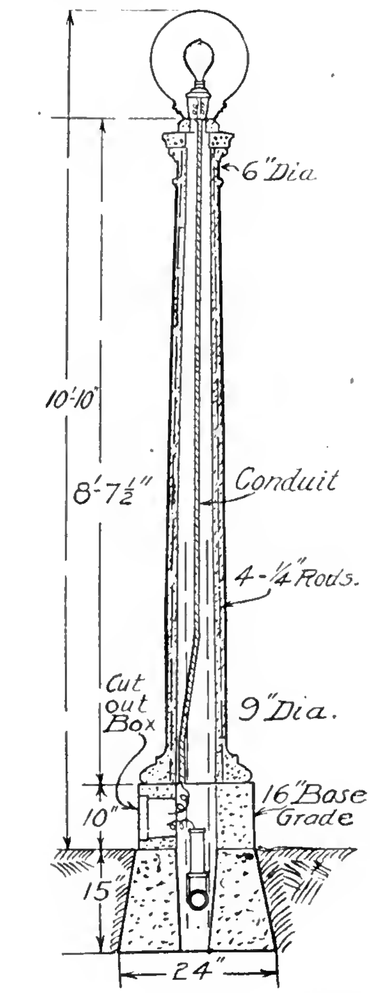
The hardest portion will be at the outside and the thickness of wall can be governed by the amount of material used. This placement of the heavier and the finer particles in concrete by centrifugal action, forming the densest mass at the outside, affords a consistent distribution in the proper proportions of the respective ingredients.

These standards are composed of a 1:3 mixture, consisting of 1 part Portland cement and 3 parts clean washed sand and gravel. This aggregate is mixed with sufficient water to permit pouring into forms which, of wood or metal as required, are of the desired outline and dimensions, and made in two or more parts as the exterior design may necessitate. The steel reinforcement is built up and placed in the mold, supported from the wall on a dead center.

When filled, the forms are locked in a machine and revolved at a proper speed to compact the mixture, sustaining the wet concrete against the walls. The exact rotating speed is dependent upon the diameter of the post. In this operation all voids are filled and the resultant product has a hard, smooth surface that cannot be obtained by ordinary tamping. The preliminary set is obtained in about 30 min. and the mold is withdrawn and allowed to stand for 24 hrs. before removal. After this time, the formed structure is capable of being handled without danger of injury to the surface; an additional curing in the open air, keeping the product thoroughly moistened, completes the process of manufacture.

A sectional view of a typical post is shown. The shaft is reinforced with four ¼-in. square twisted steel rods, equally spaced around the circumference and ¾-ins. from the outside wall. The rods are wired and held in place with No. 14 wire hoops. The standards have a hollow core, varying slightly for different types of design, but not less than 3 ins., extending from end to end. This core is concentric with the outside surface of the post.

The base, of square or octagonal pattern, as desired, and capital are cast separately under the centrifugal process. The former is provided with a 4-in. x 4-in. x 6-in. cut-out box with concrete cover. Foundations for the standards are cast in place, reinforced with



Concrete lighting standard manufactured by the centrifugal process.

⅜-in. twisted steel rods 5 ft. long in center, and the post securely anchored to this footing.

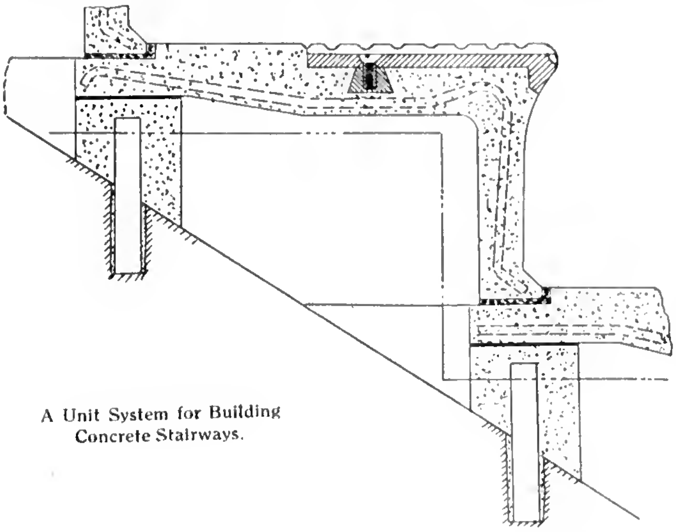
In finished surface these standards resemble cut or polished stone, which has resulted in the trade name of Marbelite. The post being hollow, is accordingly lighter than a solid column, and at the same time, is considerably stronger. Tests for absorption show that the surface of these posts take up less than one-half the moisture absorbed by well tamped concrete of the same mixture in a like period of time.

While this method of concrete manufacture is suitable for other products of post or column type, it has become particularly applicable in making reinforced concrete electroliers, and extensive activity is being given this line of operation. Classic designs modeled after Greek and Roman architecture are being adopted for various column types, supplemented by bases and capitals of harmonizing pattern.

Unit Concrete Stairway Construction

The method of casting unit stair concrete steps, which greatly facilitated the construction of concrete stairways for subways in Boston, is described by W. B. Conant, in "Concrete." The old method of setting up a timber form for each flight of stairs was found expensive because a considerable amount of lumber was destroyed in removing the forms. A unit system of casting each step was worked out, which proved to be from 33 to 50 per cent. cheaper.

The plan of casting is as follows: a cypress form of sufficient length to carry two 8-ft. lengths is used to give the face of riser and tread; i.e., the stair is cast in an inverted position. The base plate, 7 in. wide by 3/8 in. thick, to which a corrugated "safety tread" is attached, is laid face down on the form. Reinforcement consisting of 1/4-in. deformed bars, as indicated in an accompanying illustration, are placed in position; lateral rods bent to conform with the elbow of the unit are spaced at about 2-ft. 6-in. intervals in the length and wired to the longitudinal rods, the reinforcing being cast 1/4 in. from the outer surface.



A Unit System for Building Concrete Stairways.

End bulkheads are set in position and over these is placed the form for the back and the under side of the unit. This is screwed to the bulkheads.

Then the form is filled with a mixture consisting of 1 part Newburyport sand, 1 part cement, 1 part stone dust, 1/4 in. diam. and finer, and 1/2 lb. lampblack, the materials being measured by volume. Standard stairs are of 7-in. riser and 11-in. tread, with tread 1 1/2 in. thick and riser 1 1/4 in. thick.

As the concrete sets, the form is carefully troweled off to a finished surface, it being necessary to get an absolutely uniform thickness.

The unit is allowed about 24 hours to set; then the front form is removed and the riser finished. After one more day, the unit is turned over and the tread finished. Each stair is allowed to cure at least one week.

Preliminary to erecting, a flight of concrete stringers is cast against either wall, and for a wide stairway another stringer in the middle, each 8 in. to 12 in. wide. The practice is to snap a chalk line on either wall for a nosing line, and to set each unit to this, beginning with the bottom stair. Units are laid in a 1:1:1 mortar and where conditions make it necessary the spaces under the stairs are grouted with a similar mix through holes 1 1/2 in. in diameter cast in the treads by means of pipe sections. Otherwise, if the space beneath the stairs is accessible, the space is concreted from below.

Clayburn Firebrick & Clay Co., Ltd.

The Clayburn Firebrick & Clay Co., Ltd., Clayburn, B.C., are doubling the capacity of their plant by the erection of additional buildings and the installation of more machinery. The property of this large plant comprises over 800 acres about a mile from the Clayburn station of the British Columbia Electric Railway and includes the village of Clayburn, which is owned by the company and maintained for the employes. This village is equipped with all modern improvements—sewage system, electric light, and street lights.

Five miles of electric railway are operated by the company, as well as a line from the plant to Clayburn station. Mechanical operation throughout the entire works is by electricity. Their large mine, which is in Sumas Mountain, contains openings for seven different clays and shales of a variety, it is claimed, not existing anywhere else in the world. The clays run from from buff to bright red, covering practically the entire field of clay goods included in vitrified brick, and the company are now experimenting on paving brick. It has been found that on mixing two different clays a perfect non-absorbent brick was secured, which is now standard for the Vancouver sewerage system. All that is now required to perfect a vitrified paving brick is to combine the non-absorbent quality with toughness and in so doing the first vitrified brick manufactured in Canada will have been secured.

The material now in sight in the various clays—and the property has barely been touched—will last eight years and it is estimated that there will be sufficient raw material available to last for generations.

The importance of this Clayburn industry can be seen by the following figures of last year's output: 692 tons of prepared fire clay; 315,000,000 common brick; 250,000,000 pressed brick; 364,000,000 cut brick; 1,823,000 fire bricks; 839 tons of special goods (chiefly fire brick shapes); 217 tons of drain tile, and 432 tons of sewer pipe. The capacity of the plant as present is 25,000 fire brick per day, in addition to other wire-cut goods, in a ten-hour shift. Hand-made brick for building and dry-press brick can be turned out at the rate of 30,000 to 40,000 per day, and should building activity warrant, twenty extra employes could easily be accommodated.

At the present time the plant is working on a large order for the Trail Creek Smelter, which will be ready in a few weeks. Clayburn products have figured largely in building activity in Vancouver, being contained in the Hotel Vancouver and the big new C.P.R. station. The company has also, after persistent effort, succeeded in getting a strong foothold in the United States and have recently completed large orders in the States of Oregon and Washington.

The Clayburn Firebrick and Clay Company are the sole manufacturers of fire brick in Canada and it is one of the few industries unprotected by tariff regulations, while all other makes of clay products imported are subject to a 20 per cent. duty, fire brick comes in duty free. The present firm took over the establishment from the Vancouver Fire Brick & Clay Company in 1909, the officers being: President, W. H. Armstrong; vice-president, A. L. Russell; secretary, J. J. Plommer. Mr. J. B. Millar is general manager, and the Board of Directors includes Alex. Morrison, Rodge O'C. Miller, C. C. L. Wilson, J. H. Roaf, and Roy Miller. Of the total clay goods from Canada exhibited in the Canadian Building at the San Francisco Exposition, Clayburn products comprised one-third.

Manufacturing Concrete Fence Posts

METHODS employed by the New York Board of Water Supply in manufacturing reinforced concrete fence posts in connection with their work on the Catskill Aqueduct, were described by R. N. Wheeler in a paper before the New England Water Works Association recently. These posts were cast in thin metal forms in a horizontal position. Two methods were used, namely, the table and the battery methods. In the former the moulds were placed on a skeleton table, while in the latter a small steel car with hinged ends, designed to hold five layers of six moulds each was used. The table method was generally the more satisfactory of the two. It required a little more floor space, but it allowed better access to the forms for trowelling the faces of the posts at the proper time.

Mr. Wheeler gives the following hints as the result of his observations:

1. Moulds should be coated with a thin film of oil.
2. Concrete aggregates should be of two sizes, well graded; the fine up to 1/4 in., and the coarse from 1/4 to 1/2 in. for the smaller sections of post and 1/4 to 3/4 in. for the larger.
3. The mixture must be very accurately proportioned, analyses being desirable to determine the exact proportions. Generally about one part of cement to three parts by volume of aggregates gave the best results.
4. The concrete must be thoroughly mixed and of wet consistency.
5. The ends of moulds must be sealed tightly with clay, plaster of Paris, or cement, to insure good tops.
6. The air must be expelled by joggling and running a trowel back and forth through the mixture and along the sides of the mould while placing.
7. The reinforcement must be placed in correct position. This can be accomplished without a spacing device after a workman becomes skilled.
8. The reinforcing metal, particularly round wires, should be thoroughly rusted or nicked to give a proper bond. Bending the ends of these wires back 180 degs. gives good results. As received from the mill, these wires are greasy from the drawing process, and it is necessary to hasten rusting by the use of a weak acid afterward neutralized. Posts tested to failure show that unrusted straight wires pull through, whereas properly rusted ones, or those with ends bent, break. It has been suggested that running the wire through a barbing machine such as is used in the manufacture of barbed wire nails would deform it sufficiently to give a good bond. This would add not over one-half cent per pound to the cost.
9. Posts must be properly cured. They can be removed from the moulds in 36 hours, and may be stood in a vertical position and water sprayed over them from suitably arranged piping, or preferably they may be spaced in a horizontal position and covered with sand or sawdust kept wet. Curing should cover at least two weeks, and better four.
10. The rounding of edges of the exposed face can be accomplished in the form, but better by rubbing with a carborundum brick after erection and before the wire is stretched. If fencing is attached by wrapping wires, rough edges assist in holding the wires.

Welding Methods in Repair Work

The method adopted by the Pennsylvania Railroad for reconstructing cast-iron resistance grids of electric locomotives is as follows:—The grids are first sorted into four classes. The best are retained for reassembling; those slightly burned are ground on an emery wheel, while badly burned ones are re-ground and used at the insulated joints, the surfaces being separated by mica. The remainder are repaired whatever their condition. Broken grids are placed on a jig so that there is 3/8 in. clearance between the parts to be joined. A mould formed of old carbon brushes is placed around this space, and the crack is forced open 1/16 in. and the grid clamped to the jig to provide for contraction in cooling. After welding, and when the metal has cooled to a dull red heat, the clamp is removed to prevent breakage by contraction. The average cost of this operation is 10 cents, while a new grid would cost $1.05. The resistance units, after being re-ground or welded as described, are assembled on Mn-steel rods for welding, these being very hard and not affected by high temperature. It is found that in welding, the molten metal does not adhere to these rods, and they enable the holes through which they pass to be kept smooth. A fire-clay backing is employed to prevent the molten iron from flowing down between the grids. The bottom and side edges of the contact surfaces are then welded and the rods removed, after which the grids are reassembled on the insulated rods with mica washers between the joints, and the A-frames are put in place. The insulation is then tested with 1,000 volts alternating current.

This method has proved to be cheaper than acetylene welding, the details of cost being as follows:—

Removing burnt grids from locomotives, 2 men, 2 hours at 50c. per hour	$1.00
Grinding, cleaning, and repairing grids, 1 man, 2 hours, at 34c. per hour	.68
Assembling grids for welding, 1 man, 1 hour, at 34c. per hour	.34
Welding grids, 1 man, 3 hours, at 34c. per hour.	1.02
Assembling grids on locomotives, 2 men, 3 hours at 50c. per hour	1.50
Cost of electrical energy, 33 units at 1c. per unit	.33
	$4.87

The cost of the former method of replacing burnt sections by new ones and grinding and cleaning those slightly burned amounted to $14.40.

Obstacles to successful welding are sand holes, blow-holes, and slag piles.

Copper lugs have been successfully welded to cast-iron grids by shortening the arc to 1/2 in., and using 150 amps. The arc is confined to the iron until welding temperature is reached and then brought in contact with the iron and copper. Copper-oxide gas and copper slag are sources of trouble; the gas is heavy and masks the weld, while the slag, being but slightly darker than the molten copper, is difficult to distinguish from it.

The Toronto Bureau of Municipal Research have just issued their second annual report, covering the year ended February 29, 1916. The report covers what the Bureau has been working at during the year; what advances have been made by the civic government in city administration and by the community as a whole in community activities; and finally suggests some advanced steps for the future.

Canadian Overseas Railway Construction Corps Doing Good Work at the Front

IT has been truly said that modern war is engineering applied to manslaughter. It is an engineer's business, according to the classic definition, to use the great forces of nature for the service of man. How far the term, service, may be applied has

Lieut.-Col. C. W. P. Ramsay, O.C.

been brought out by the European war, where modern science is being applied to the destruction of the human race. The engineer may be held directly responsible for the mammoth scale and scientific manner in which this modern war is prosecuted.

The progress of the European war has demonstrated that engineers are needed as they never were before to insure the success of any great offensive or defensive movements. The work of the engineer has been justly recognized and the splendid service done by our Canadian engineers at the front, has been highly appreciated by the allied commanders. The work of the Canadian Overseas Railway Construction Corps, Colonel C. W. P. Ramsay, O. C., has attracted particular attention. The corps has already built many miles of track at strategic points, and is now engaged in surveys for further construction. The sudden demand for troops and supplies creates a condition which requires that means of communication and transportation should be supplied as rapidly as possible. The equipment necessary to carry on such construction must necessarily be the most efficient possible. To meet the conditions, the Canadian Government recently purchased for the C. O. R. C. C. a considerable amount of equipment, including some large steam

65-ton steam shovel purchased by the Canadian Government for the Canadian Overseas Railway Construction Corps.

Self-propelling track layer for the C.O.R.C.C.

shovels, weighing 65 tons each, capable of excavating at the rate of 150 to 200 yards an hour, and also some self-propelling extension track pile drivers. This equipment was purchased by Colonel Ramsay's colleagues in the engineering department of the Canadian Pacific Railway, and is being prepared by that company at the request of the Canadian Government for shipment to the corps. The illustrations show the types of machinery that will be sent. They bring home forcibly the immense proportions on which modern warfare is being waged.

Of the non-commissioned officers and sappers that enlisted on the formation of the C. O. R. C. C., eighteen have received commissions in the Royal Engineers, a remarkable tribute to their efficiency, while Colonel Ramsay and Major Harvey have been mentioned in dispatches. Work has often to be carried out under fire, and although there have been many narrow escapes, there have as yet been no casualties.

The Canadian Pacific Railway is engaged on a large programme of broken stone ballasting on a portion of its eastern tracks in the vicinity of Montreal The main line from Windsor Station to Vaudreuil, 24 miles, and from Place Viger station to St. Therese, 20 miles, is now being being ballasted with broken stone.

Two Scholarships for C.P.R. Employees

Mr. George Bury, vice-president of the Canadian Pacific Railway, announces, in a special circular, that two free scholarships, covering four years' tuition in the Faculty of Applied Science in McGill University, are offered to apprentices and other employees enrolled on the permanent staff of the said company, and under 21 years of age, and to minor sons of employees, the same being subject to competitive examination.

The competitive examination will be held at the University, Montreal, and at other centres throughout Canada, in June, 1916. The candidates making the highest average and complying with the requirements of admission will be awarded the scholarships and have the option of taking a course in any department of applied science.

The scholarship will be renewed from year to year, to cover a period not exceeding four years, if, at the close of each session, the holder thereof is entitled, under the rules, to full standing in the next higher year. In case a scholarship holder finds it necessary to interrupt his course for a year or more, notice must be given at the close of the session to the railway company and to the head of the railway department of the university, in order that the scholarship may be open to other applicants.

In order to establish prior claim to the next available scholarship, notice of the student's intended return must be given to the railway company and the head of the railway department not later than January 1st preceding the opening of the session available. Applications for certificates entitling eligible persons to enter the competition should be addressed to Mr. C. H. Buell, staff registrar and secretary pension department, Montreal.

On Active Service

The following members of the Calgary Branch of the Canadian Society of Civil Engineers have enlisted for active service:—

Members.—H. B. Muckleston, F. R. Burfield, Col. Paul Weatherbae.

Associate Members.—P. J. Jennings, H. R. Carscallen, F. S. Dyke, G. R. Elliott, J. A. Symes.

Juniors.—R. L. H. Goodday, J. H. Jones.

Students.—J. B. McLean.

Associate of Branch.—G. H. Whyte.

Edmonton Branch C.S.C.E. Elects Officers

A special meeting for the election of officers was held by the Edmonton branch of the Canadian Society of Civil Engineers on the 10th instant at the Cecil Hotel. About twenty members of the society resident in Edmonton were present at an informal dinner which was served at 7 o'clock. The following officers were elected for the ensuing year commencing in October next:—chairman, L. B. Elliot; vice-chairman, J. Chalmers; secretary-treasurer, C. A. Robb; executive committee, A. T. Fraser, D. J. Carter, J. L. Cote, D. Donaldson.

A number of the engineers present spoke briefly alluding to the large number of the members who had enlisted in the service of King and Country, the signs of returning business activity in the west, the great undeveloped resources, the revival of development work following the close of the war, and the consequent demand for qualified civil engineers. After the disposal of other regular business brought before the branch, the meeting adjourned at 9.30 o'clock.

Personal

Mr. W. S. Robertson has resigned his position as general manager of the Electric Power Company recently taken over by the Ontario Government, and goes to the United States to accept a responsible position.

Mr. Andrew F. Macallum, for many years city engineer of Hamilton, has been appointed Commissioner of Works of the city of Ottawa.

Mr. A. F. Macallum, recently appointed Commissioner of Works, Ottawa.

Mr. L. G. Ireland, local manager of the Brantford Hydro-electric Commission, has been appointed engineer to the Hydro-electric Power Commission of Ontario, in charge of the lines in the Trent Valley area recently taken over from the Electric Power Company.

Mr. L. G. McNeice has been appointed general manager of public utilities of the town of Wallaceburg. Mr. McNeice formerly represented the consulting engineering firm of Chipman & Power, Toronto, in the city of London, and more recently was engineer-in-charge for them in the installation of the waterworks and sewage systems at Wallaceburg. He is a science graduate of Queen's University.

Canadians who have gained distinction in professional and educational work were given honorary degrees by the University of Toronto at Convocation on Friday. Amongst those who were honored were Mr. Frank Darling, one of Toronto's best known architects, and Prof. Frank D. Adams, Ph.D., D.Sc., F.R.G.S., F.R.S., of McGill University, who is widely known as a geologist and educationalist, and past-president of the Canadian Mining Institute, International Congress of Geologists, the Montreal Natural History Society, and the McGill Graduates' Society.

Under the terms of a new by-law, Howard Ferguson has been appointed building inspector at Trail, B.C., and applications for permits for repairs, alterations, or new structures of any kind, must in future be referred to him.

Obituary

The death is announced of Mr. A. N. Mungall at his home at Fredericton, N.B. Mr. Mungall was a young man, only 28 years of age. He had followed the occupation of civil engineer for a number of years, and was engaged in the construction of the National Transcontinental and other lines.

Mainly Constructional

East and West—From Coast to Coast

Reciprocity with the State of Michigan takes effect on May 25.

The Canadian Drawn Steel Co., Ltd., Hamilton, Ont., have taken out a charter.

The Canada Forge Company will make a $50,000 addition to their plant at Welland Ont.

The planing mill of Lewis Fick & Son, at Guelph, Ont., was recently destroyed by fire.

J. H. Sticht & Company, manufacturers of ornamental iron, Longueuil, Que., have registered.

The Trades and Labor Council of London, Ont., propose to build a temple in that city, to cost about $45,000.

There were 29 building permits issued at Waterloo, Ont., for the month of April, representing a value of $48,495, a decrease from the same period last year of $9,330.

Satisfactory progress is being made on the site of the G.N.R. depot at False Creek, B.C., and it is expected that work on the superstructure will commence shortly.

Arrangements were completed with reference to the interchange of motor licenses between Ontario and the State of New York, and became effective on the 20th inst.

Building permits to the value of $20,086 were issued at Welland, Ont., during the month of April this year, as compared with $55,032 during the same period last year.

The value of the building permits issued in Guelph, Ont., during the month of April is $21,812. This makes a total value of the permits for the first four months of the year $24,227.

There is a rumor that the Crown Portland Cement plant at Wiarton, Ont., may be sold, and that instead of cement will be manufactured magnesia, hydrate of lime, potash, etc.

A by-law will shortly go into effect in Westmount, Que., authorizing the formation of an architectural commission to supervise the outside design and construction of buildings, public and private.

The Dominion Government is taking no action as regards the Daylight Saving scheme. Premier Borden states that he thinks it is better for the municipalities to deal with the matter for the present at least.

The Department of Public Works of Ontario has approved of a plan to expend $145,000 during the present year on additional good roads in York County, 40 per cent. of the cost of which the Provincial Government pays.

The number of building permits issued in the city of Hamilton, Ont., for the first four months of this year was 205, amounting to $451,700, as compared with 163 during the same period in 1915, representing a value of $387,183.

The Council of Esquimault, B.C., is taking proceedings against Thomas E. Young, contractor, to recover some $5,000 which, it is alleged, was overpaid him by last year's Council for excavation and other work in connection with sewer contracts.

It is stated that the Canadian steel companies have contracted so far ahead that they cannot now accept orders except for delivery in the far-away future, and that as a result of this unusual activity they are all showing very large earnings.

Mr. Paul Janoushevsky, of the Vladicaucase Railway, Russia, has been visiting Vancouver, B.C., and Portland, investigating the construction of bridges. On his return to Russia he will superintend the construction of the first direct lift bridge to be erected in that country.

The work on the big Centre street reinforced concrete bridge at Calgary, Alta., is progressing satisfactorily. The first two spans are practically completed, and the false work for the third is being set up. It is estimated that the bridge will be open to traffic before the end of the year.

The amount of the building permits issued in Chatham, Ont., during April this year, was $23,570, as compared with $13,200 in April, 1915. The total value of the permits issued for the first four month of the year was $40,120, a decrease of $12,280 from the same period last year.

The first steel rolling mill in the Province of British Columbia recently started operations at Port Moody. The mill when completed will be in two units, but only one of them has been erected as yet. The new concern is under the presidency of Mr. E. Francis.

Work on the aqueduct of the Greater Winnipeg water district has been resumed. Construction had been stopped, owing to the belief that the condition of the soil possibly did not warrant the pouring of concrete according to the original design. The design has been slightly changed.

By-laws were carried recently by the Council of York Township, Ont., providing for the raising of sums aggregating nearly $55,000, to cover improvements made last year. The work, which consisted of the laying of concrete sidewalks, sewers and cement roadways, was the most extensive ever carried out in York Township.

G. N. Hatfield, road engineer, in an interesting paper read before the Rotary Club at St. John, N.B., outlined plans for building a 215 mile highway from St. Stephen through St. John and Moncton to the border of Nova Scotia, using part of the revenue from automobile licenses for carrying out the work. The club approved the plan.

The work on the construction of Welland ship canal for which contracts have been given out, is progressing favorably, according to a statement made by Chief Engineer Weller, and all indications are that with the exception of the Thorold section, where considerable blasting had to be done, operations will be completed on schedule time.

Tenders are being called in East Trail, B.C., for the construction of one mile of road and the laying of over 8,000 feet of mains which were recently purchased in Vancouver for a proposed water system. A reservoir is to be situated at an elevation of about 200 feet above the townsite, and the water will be impounded about one mile up Randall Creek. J. D. Anderson is looking after the installation for the owners, McKelvey & Randall.

Proposals were made by a Niagara Falls deputation recently received by Hon. Mr. Reid, Acting Minister of Railways and Canals, that the dam and lock, which it was intended to place at Port Robinson in order to raise the Welland river to the level of the canal, should instead be placed at Montrose, and also that the proposed power canal be made a ship canal from its intake at Montrose to a point south of Lundy's Lane, in the Township of Stamford.

The plans of the new Parliament Buildings at Ottawa, as drafted by Architects Pearson, of Toronto, and Marchand, of Montreal, have been under consideration by the Commission of both Houses, and it has apparently been decided to add a fourth storey to the building. The additional cost of the enlargement will probably be something over $1,000,000. According to preliminary estimates the expenditure on the completed structure will be nearly $5,000,000.

The Winnipeg City Council have given permission to the Grain Exchange to make an addition of three stories to their building, to cost some $150,000. The architects are Over & Jordan, Winnipeg. The Council have also ratified an agreement with St. Boniface, by which the construction of the superstructure of the Provencher bridge will be erected as soon as possible. The total cost of the bridge is estimated at about $591,000, of which St. Boniface is to pay two-thirds.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks, Sewerage and Roadways

Markham, Ont.
The Village Council are calling for new tenders on the construction of about 35,000 square feet of concrete sidewalk, the first tenders being unsatisfactory. Clerk, M. White.

Montreal, Que.
The City Council propose to expend about $250,000 on the construction of asphalt and block pavements, and will call for tenders. Engineer, P. Mercier.

New Waterford, N.S.
Tenders are now being received for the construction or sewers, curbs, and gutter for the Town Council, estimated to cost $5,000. Engineer, G. J. Ross, Sydney, N.S. Closing date about June 20th.

Orford Township, Ont.
The Township Council are considering the construction of an open ditch drain, estimated to cost $4,454. Engineer, J. A. Macdonald, Ridgetown, Ont.

St. Catharines, Ont.
Tenders will be received until 5 p.m., June 1st, by the Chairman of the Board of Works, for the construction of about 5,200 feet of trunk sewer. Engineer, W. P. Near.

St. John, N.B.
The City Council are considering the construction of extensions to the waterworks system, ot an approximate cost of $230,000.

Toronto, Ont.
Commissioner of Works, R. C. Harris, has recommended the following work:—Sewers, $46,100; granite block paving, $31,697; brick block paving, $4,533; asphalt paving, $5,653; concrete sidewalk, $3,020; concrete paving, $7,700.

The York County Highways Commission propose to spend $140,000 on the improvement of roads throughout the county, and the scheme has been approved by the Provincial Government. Engineer, E. A. James, 57 Adelaide Street E.

CONTRACTS AWARDED

Humboldt, Sask.
The contract for the construction of a reservoir for the Town Council has been awarded to the Northern Construction Company, Saskatoon, at $3,880.

Laval, Que.
The contract for the construction of macadam roads for the Town Council has been let to A. T. A. Chagnon & Fils, Laprairie Village. Approximate cost, $7,000.

New Hamburg, Ont.
The Town Council have awarded a contract for the construction of reinforced concrete pavement and curbing to E. J. Holland, Ingersoll. Approximate cost, $15,000.

Windsor, Ont.
The City Council have let a contract for the construction of a quantity of concrete pavement to the Chick Contracting Company, McDougall Ave. Approximate cost, $7,500.

Railroads, Bridges and Wharves

MooseJaw, Sask.
The City Council are considering the construction of a pole dam across the valley of Thunder Creek. Engineer, George D. Mackie.

South Dumfries Township, Ont.
Tenders on the constduction of a steel and concrete bridge will be received until June 5th by the Township Clerk, Henry Maus, Paris. Engineers, Jackson & Lee, Temple Building, Brantford.

Upper Jemseg, N.B.
Tenders on the construction of bridge superstructure and approaches will be received until noon, May 31st, by Hon. John Morrissy, Department of Public Works, Fredericton. Plans and specifications at Provincial Rooms, St. John, at office of H. W. Woods, Esq., Welsford, with Slocum & Townes, Jemseg, and at the Department.

Waneta, B.C.
The Provincial Department of Public Works, Victoria, have had plans prepared for the construction of a bridge over the Pen d'Oreille River, at an approximate cost of $15,000. Engineer, Thomas Kilpatrick, Victoria.

CONTRACTS AWARDED

Sunbury County N.B.
The Provincial Department of Public Works, Fredericton, have awarded the contract for the construction of a bridge at Black Creek Mouth to Luther B. Smith, 38 Dufferin Road, St. John, N.B.

Public Buildings, Churches and Schools

Calgary, Alta.
The School Trustees propose to build two manual training buildings at an estimated total cost of $56,000, and will submit a by-law.

The erection of an auditorium at an approximate cost of $150,000, is being considered, and a special committee has been appointed, of which City Engineer Craig is a member.

Casselman, Ont.
Charles Brodeur, Architect, 63 City Hall Street, Hull, Que., has prepared plans for alterations and additions to the Parish Church, estimated to cost $6,500. Tenders will be called shortly. Frame and brick veneer construction.

Gravenhurst, Ont.
The National Sanatarium Association, 223 College Street, Toronto, propose to construct a central heating plant, a vocational building and a number of cottages at the Hospital. Architect, C. S. Cobb, 71 Bay Street, Toronto.

Hespeler, Ont.
Sketch plans are being prepared for a Roman Catholic Church, to be built on Cooper Street at an approximate cost of $10,000. Architect, J. M. Cowan, 65 Adelaide Street E., Toronto.

London, Ont.
Tenders on the erection of a Technical School will be received until June 3rd by A. E. Silverwood, Chairman of the School Board. Architects, Watt & Blackwell, Bank of Toronto Building. Estimated cost, $200,000.

Nelson, B.C.
Plans are being prepared for the erection of a building for the Kootenay Lake General Hospital. Estimated cost, $50,000.

Orillia, Ont.
Bulk of separate tenders on the erection of an addition to the General Hospital will be received until noon, May 27th, by George Thompson, Chairman of the Building Committee. Plans and specifications at office of G. H. Clark, and with the Architect, W. H. Croker, Atherley Street. Estimated cost, $10,000.

Tenders on plumbing, heating, wiring, and roofing required in connection with the erection of the Municipal Building are being received by the Clerk, C. E. Grant, and the Architects, Burke, Horwood & White, Ryrie Building, Toronto.

Ottawa, Ont.
Charles Brodeur, Architect, 63 City Hall Street, Hull, Que., is preparing plans for the erection of a dormitory and laundry in connection with the Water Street Hospital. Tenders will be called in about one month. Approximate cost, $28,500.

Sherbrooke, Que.
The contract for heating required in connection with St. Michael's Cathedral will be let by F. M. Hoadley & Company, 58 Beaver Hall Hill, Montreal. Roofing contract has not yet been let.

Vancouver, B.C.
The Department of Public Works, Ottawa, are now receiving tenders on the removal of the existing buildings preparatory to the erection of a Postal Station at an approximate cost of $124,000. Secretary, R. C. Desrochers, Ottawa.

Weston, Ont.
C. S. Cobb, Architect, 71 Bay Street, Toronto, is preparing plans for a Children's Cottage to be built for the National Sanitarium Association, 223 College Street, Toronto.

CONTRACTS AWARDED

Cartierville, Que.
In connection with the church basement now in course of erection for the Roman Catholic Congregation, the plastering has been let to F. Beaudoin & Fils, 636 Drolet Street, Montreal, and

the painting to Charles Larin, 468 Parc Lafontaine, Montreal.

Medelec, Que.
The general contract for the erection of a school has been let to Alphonse Robert, Nord Temiscamingue. Approximate cost, $4,500.

Montreal, Que.
In connection with the school and residence now being built for the Commissioners of Cate des Nieges, the roofing contract has been awarded to the Standard Roofing Company, 189 McCord Street.

Repentigny, Que.
The contract for mill work required in the erection of a school for the Roman Catholic School Board has been awarded to F. Limoges, Terrebonne.

St. Antoine de Bienville, Que.
The contract for plastering at the Parish Church has been let to Paquet & Godbout, 21 William Street, St. Hyacinthe.

St. Celestin, Que.
The general contract for the erection of a hospital for the Grey Nuns of St. Celestin has been awarded to Louis Caron & Fils, Ltd., Nicolet. Approximate cost, $18,000.

St. Christophe Pont Viau, Que.
The general contract for the erection of a Chapel and Parsonage for the Parish has been awarded to Blais & Lemieux, Ahuntsic, Que. Approximate cost, $13,500.

Business Buildings and Industrial Plants

Banff, Alta.
Tenders on labor only required in the erection of a business block for R. G. Brett will be received until noon, June 1st. Plans and specifications with J. D. Hansen and the Architect. Estimated cost, $20,000.

Burford, Ont.
The Canadian Milk Products Company, Mail Building, Toronto, propose to build a plant, at an estimated cost of $100,000. Previously reported as being at Listowel.

Carlton Point, P.E.I.
Tenders on the construction of a station, water tank, engine house, transfer platform, standpipe pit and turntable, will be received until noon, May 31st, by J. W. Pugsley, Department of Railways and Canals, Ottawa. Plans and specifications with the Engineer, Car Ferry Terminals, the Chief Engineer, Moncton, N.B., and at the Department.

Chatham, Ont.
The American Pad & Textile Company, Queen Street, propose to build an addition to their premises, at an approximate cost of $30,000.

Markham, Ont.
A Company is being formed to erect a flour mill at an approximate cost of $60,000.

Merlin, Ont.
James T. Mason has commenced the erection of an addition to his store and residence, estimated to cost $3,000. Frame, white brick, and concrete construction.

Moncton, N.B.
J. D. Creaghan Company are considering the erection of an addition to their store, estimated to cost $4,000.

Montreal, Que.
The Canadian Tube & Iron Company, Ltd., 107 Hamilton Street, have commenced the erection of a factory, estimated to cost $3,000. Brick and concrete construction.

Tenders are now being received for roofing, heating, plumbing, and electrical work required in the erection of an addition to the premises of the Canadian Consolidated Rubber Company, Ltd.

Newbury, Ont.
R. Winship is building a residence and barn, estimated to cost $3,000. Frame and concrete construction.

Ottawa, Ont.
Tenders on the erection of a factory for Grant, Holden & Graham, are being received by the Architect, James Mather, 110 Wellington Street. Brick construction. Approximate cost, $30,000.

Port Dover, Ont.
Buck Brothers are having plans prepared for a Casino, estimated to cost $10,000.

Quebec, Que.
Bedard & Kippan, 12 Cartier Avenue, are having new plans prepared for the theatre which they propose to build on St. John Street. Architect, A. G. Nosworthy, Quebec Railway Building. Estimated cost, $6,000.

Renfrew, Ont.
The Renfrew Electric Manufacturing Company, Ltd., have commenced the erection of an addition to their premises, estimated cost of $5,000. Brick and concrete construction.

The Renfrew Curling Club contemplate the erection of a rink, at an approximate cost of $7,000. Secretary, R. D. Scott. Brick and concrete construction.

Simcoe, Ont.
The Hall Glove Company, Jersey City, N.Y., propose to build a textile factory, at an approximate cost of $25,000. Particulars from Charles Philip, 52 Bay Street, Toronto.

St. Thomas, Ont.
A. S. Smith, Palace Livery, propose to build an office building, and will prepare plans. Estimated cost, $7,000.

Tilbury, Ont.
Plans are to be prepared immediately for a station to be built for the Michigan Central Railway, at an approximate cost of $6,000. Brick construction. Superintendent, F. Williams, M.C.R., St. Thomas.

Toronto, Ont.
The McClary Manufacturing Company, 177 King Street W., have started work on an addition to their warehouse, estimated to cost $3,500. Brick construction.

G. I. Hambly, 372 St. Clarens Avenue, is building a pair of store and apartments at St. Clair Avenue and Kennedy Street, estimated to cost $6,000. Smaller trades will be let. Brick construction.

Eustace G. Bird, 6 King Street W., has been appointed Architect for the proposed store to be built for Murray-Kay, Ltd., 17 King Street E. Steel, terra cotta, and brick construction.

Vancouver, B.C.
Plans have been prepared for the erection of a garage for the British Columbia Sugar Refinery Company. Reinforced concrete construction. Approximate cost, $9,000.

The Canadian Northern Railway propose to build a large hotel, and have secured an option on a site.

Victoria Park, Ont.
The Michigan Central Railway propose to build a large frame storehouse, at an approximate cost of $7,000. Superintendent, F. Williams, St. Thomas, Ont.

Weston, Ont.
Work is about to start on the erection of a factory for T. A. Russell, c/o. the Russell Motor Company, King and Duncan Streets, Toronto. Steel and brick construction.

Windsor, Ont.
Walker & McPhail, Architects, Tuson Building, are preparing sketch plans of a store to be erected on Ouellette Avenue, for a Syndicate. Steel, brick, and concrete construction. Approximate cost, $20,000.

CONTRACTS AWARDED

Brantford, Ont.
In connection with alterations to the premises at 30 Market Street, for W. T. Jones, the contract for heating and plumbing has been let to T. J. Minnes & Company, 9 King Street, and the electrical work to Fred Webster, 211 Colborne Street.

Halifax, N.S.
The general contract for alterations to a restaurant building for Bonds Ltd., Barrington Street, has been let to the Eastern Investment Corporation, Ltd., Cragg Building. Approximate cost, $20,000.

Harrow, Ont
The general contract for the erection of a factory for the W. Clark Company, Ltd., 83 Amherst Street, Montreal, has been let to Munn & Shea, 6 Cuthbert Street, Montreal. Estimated cost, $15,000.

Kingston, Ont.
The general contract for the erection of a storehouse for the Frontenac Moulding & Glass Company, Kingston Junction, has been awarded to Charles Hermiston, 84 Collingwood Street. Approximate cost, $5,000.

London, Ont.
The general contract for the erection of an addition to the premises of E. Leonard & Sons, York Street, has been awarded to John Hayman & Sons, Wellington Street. Brick and concrete construction. Estimated cost, $8,000.

The contract for stone work required in alterations to a store for Miss F. Mitchell, 114 Dundas Street, has been let to Nobbs Brothers, C.P.R. and William Street, and the plumbing to F. C. Hunt, Richmond and Kent Streets.

Maisonneuve, Que.
The general and masonry contracts for the erection of an addition to the premises of the Montreal Last Company, 562a LaSalle Avenue, have been awarded to L. Labrecque, 422 Parc Lafontaine Street, and the roofing, heating and plumbing to J. E. Hardy, 666 Papineau Avenue.

Melbourne, Ont.
The general contract for the erection of a residence and barn for James Carrothers has been let to Watson & Mc-

Tenders and For Sale Department

TENDERS

For the erection of the New Technical and Art School on Dundas Street in the City of London, sealed tenders are invited, bulk and separate for all trades, except the heating and ventilating and wiring, for which separate sealed tenders must be submitted.

All tenders will be received not later than 12 o'clock noon on **Saturday, June the third, 1916**, at the office of the Secretary of the Board of Education at the City Hall.

A duly certified cheque for five per cent. of the amount of the bid must be enclosed with each tender. Plans and specifications may be viewed at the offices of the Architects, A. E. Nutter, Rooms 15-16, Dominion Bank Chambers, and Watt & Blackwell, Bank of Toronto Chambers.

Plans for heating and ventilating and wiring may be seen at the offices of the above Architects or at the office of H. P. Elliott, Heating Engineer.

The lowest or any tender not necessarily accepted.

A. A. LANGFORD,
Chairman of Industrial Advisory Committee.

19-

Tenders for Dredging

Sealed tenders, addressed to the undersigned and endorsed "Tender for Dredging, Port Maitland," will be received at this office until 4 p.m., on **Tuesday, May 30, 1916**, for dredging required at Port Maitland, Ontario.

Tenders will not be considered unless made on the forms supplied, and signed with the actual signatures of tenderers.

Combined specification and form of tender can be obtained on application to the Secretary, Department of Public Works, Ottawa. Tenders must include the towing of the plant to and from the work.

The greater portion of this work will be required to be done by an hydraulic dredge.

The dredges and other plant which are intended to be employed on this work shall have been duly registered in Canada at the time of the filing of the tender with the Department, or shall have been built in Canada after the filing of the tender.

Contractors must be ready to begin work immediately upon notification of the acceptance of their tender.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, for five per cent. (5 p.c.) of the contract price, but no cheque to be for less than fifteen hundred dollars, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, May 19, 1916.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department. 21-21

Found—One Hour

On Sunday, May 21, Great Britain adopted the daylight saving scheme. It seems to us that there is everything to commend it and nothing to criticize. According to Premier Borden, daylight saving legislation in Canada is to be left to local option. A number of Canadian cities, however, have already adopted the system of getting up an hour earlier during the summer through the expedient of putting the clocks forward.

Like many other reforms the daylight saving scheme has been rather skeptically regarded. The success of the scheme will depend largely on the unanimity with which all the important interests in the Dominion support it. If one important interest adheres to the old schedule, the success of the scheme is impaired. It can be definitely stated, however, that its success in the municipalities that have tried it out shows conclusively how beneficial it is.

With everyone preaching war economy to his neighbor, this seems like a splendid opportunity to apply his form of thrift. Daylight saving means economy—reduction of light and fuel bills. Daylight is the natural time for work and recreation, even as the period of darkness is the proper time for rest. Observe the forces of nature—to sleep while the sun is shining is a reversion of nature's laws.

The chief benefits to be derived is from the standpoint of better health. A whole hour of daylight is gained for recreation, the nicest period of the day, that is, the hour at the present time between about five and six o'clock. One more hour for recreation, for social pastime, or for any of the small amenities of life; outdoor recreation and refreshment to banish the cares of the day and fit the body for sound and refreshing sleep, giving everyone renewed energy to go to his daily work and to do it more profitably both for himself and his employer.

Once changed, the objections of the chronic lay-a-bed to getting up an hour earlier are unconsciously overcome. Breakfast at 8 o'clock will still be at 8 o'clock. Things will go just the same as before; one's habits need not change except to take advantage of the extra hour. The factory whistles will still whistle at seven and six. It seems like a thrifty undertaking in times when thrift and economy are our motto. Leaving it to local municipalities to decide for themselves, however, is not going to give the most harmonious results. It will cause friction, for example, between one town having the system and another without it. It seems as if it would be better for the federal government to decide the matter for all. Great Britain, and many other continental countries have adopted a federal measure—why not Canada?

Town Planning a Modern Necessity

THE mad onrush of modern industrialism may be held largely responsible for the present condition of some of our larger towns and cities, with their utter lack of beauty and inconvenient transportation facilities. Municipalities are beginning to realize the state they have fallen into after a century of nothing but rush—and are stopping to consider. The subject of town planning has been very much in the public eye of late. It is a scheme which, it seems to us, might be appropriately considered at the present time. Involving as it does little expense in its consideration, it might provide a means for municipal activity that may be so advanced, now, that it could be immediately applied as a remedy for the demand for employment that will arise when the European war is over. The actual development of the scheme must wait, of course, for the return of normal times, but it could be so far advanced as to be ready for immediate execution when the time warrants.

W. R. Davidge, a district surveyor in the Old Country, who is remarkably conversant with town planning conditions in most of the Canadian and United States cities besides those of Great Britain, points out clearly the need of town planning, in a paper before the Surveyors' Institute, London, which is published elsewhere in this issue. Mr. Davidge confines himself to the general subject of town planning and the consideration of its broader principles. In Great Britain, with its congestion in the larger cities, the creed of town planning may be expressed as "more air, more accessibility, more attractiveness," or in other words, health and social well-being, especially as applied to prospective building land around the present towns and cities. Canadian and United States cities, on the other hand, regard town planning from one of two ideals, either the "civic centre" ideal or the "rapid transit" ideal, both of which smack like "good business proposals," and "business" is the keynote of American cities.

One thing stands out clearly, no matter what viewpoint is considered, and that is, the paramount need for some form of town planning at the present time, whether it be to clean up the slums within the present city limits or to plan for future development. Whether one wants merely a pretty city with lots of parks and public space, or one with good facilities for rapid transit, or both, the universal need for town planning is evident. Such a system cannot be called, as it were, a stock article, but must be made to order. A town's plan must be its own.

The question of tall office buildings and the overflowing of the business section into the residental district are items that must be considered in the town's plan. That an efficient system of rapid transit is one of the important items, is quite evident, yet this all-essential detail is often omitted in laying out a system. For many people, town planning begins and ends with the planning of roads. It is true, however, that the main roads into and out of a town are the skeleton on which the plan will hang together.

The subject of town planning in which provision for the future must be made, is not one man's job, but many. Every profession and every business should be heard and the plan should be the result of the cooperation between all interests, as interpreted by the engineer and the architect.

Letters to the Editor—Should Engineering Societies Pass on Public Questions

Calgary, Alta., May 19, 1916.

Editor Contract Record:

The Executive Committee of the Calgary Branch of the Canadian Society of Civil Engineers have authorized me to write to you, setting forth the facts concerning its action which was referred to in your issue of May 10, 1916, p. 445, under the title, "Should Engineering Societies Pass Upon Public Questions?"

Attached hereto is a statement of the facts. The question as to what action Engineering Societies can and should take in public matters in which the profession is interested has been much discussed lately. This is a record of how we handled such a case, and it is thought that it will be of sufficient interest to other engineering bodies to justify its publication, especially since a misleading reference has already been made to our action in your issue above referred to.

Yours truly,

Sam. G. Porter,

Secretary-Treasurer.

"Should Engineering Societies Pass Upon Public Questions?"

The author of the article under this heading in Volume 75, No. 17, Page 818, of the "Engineering News," undoubtedly refers to the action taken by the Calgary Branch of the Canadian Society of Civil Engineers in connection with the controversy over certain features of the construction of the large reinforced concrete arch bridge being built over the Bow River by this city.

The evident intent of the article is to create the impression that the society was not justified in taking the action which it did and that in so doing it was encroaching upon the rights of the consulting engineer.

The author passes over the facts of the case upon which the action of the society (of which he is a member) was based with one or two statements which are misleading.

As the precedent established by the society in the attitude which it assumed is new, a concise statement of facts will be given in order that the profession may judge for themselves of the merits of the action.

For a period of nearly a year previous to the matter being taken up by the society there had appeared in the public press a considerable adverse criticism of the engineering department of this city.

This came primarily from an alderman who had previously held the position of Waterworks Engineer for the city, but under a policy of economy his services had been dispensed with and the Waterworks Department placed under the City Engineer. He thereupon entered politics and was elected an alderman. He also opened an office for the practice of Consulting Engineering; hence his statements and opinions regarding engineering matters received far more consideration from the public than otherwise would have been the case. The work of the engineering department was greatly handicapped by this continual fault-finding.

Finally this criticism focused itself upon the construction of a large concrete arch bridge being built by the city over the Bow River at Centre Street, and charges were made to the City Council by this alderman which reflected upon the ability and good judgment of those connected with the city engineering department.

The City Engineer was an associate member of the American Society of Civil Engineers, and the local members of this organization realizing the serious nature of this criticism took the matter up with him, and after hearing his side it was the unanimous opinion of those present that any further discussion of these matters in the daily press could serve no useful purpose and that the local engineering profession would lose prestige if it was allowed to continue.

Furthermore, it was evident that if the facts were as he presented them, his reputation as an engineer was being attacked largely for political purposes. As this was a matter between engineers, it was felt that it should be settled within the profession and that the local branch of the Canadian Society of Civil Engineers was the proper body to which to appeal. This would be quite fair as neither party to the controversy was connected with this organization and its membership was thoroughly representative of the local profession, as well as containing some of the larger ratepayers of the city. At the same time the attention of the City Engineer was called to the fact that if the society could be prevailed upon to take the matter up that he must be prepared to abide by the findings of that body regardless of the consequences.

With this understanding the whole matter was laid before the executive board of the local organization.

In the meantime the City Council had ordered the two commissioners and mayor to investigate the matter and report. The alderman had been prevailed upon to submit the verbal charges in writing and the City Engineer requested to answer them in the same manner.

In the interim between the submission of the charges and the answers, the executive board of the society unanimously decided to offer its services gratis to the Board of Commissioners to investigate and report on the matter. A set of resolutions embodying this offer was then drawn and adopted at a general meeting of the society.

The city accepted the offer and requested the society to proceed.

Three members of the branch were then selected to act as a committee to make the investigation.

The meetings were public and held in the committee room of the council chamber at the City Hall, and the proceedings recorded by a stenographer furnished by the city. The alderman preferring the charges refused to appear befor this committee for examination and they had no power to compel attendance. On the other hand, the City Engineer, the engineer in charge of the design and construction of the bridge, and the city chemist, who had charge of the city testing laboratories, appeared and submitted very willingly to a thorough examination on the points at issue.

In brief, the charges were as follows:—

(a) The use of unsuitable re-rolled steel in the structure, and extravagance in the testing of same.

(b) Neglect or carelessness in not carrying the foundations of the north retaining wall to rock.

(c) Failure on the part of the engineering department to submit the design to a consulting engineer for endorsement, it having always been understood that such a course would be followed.

(d) The purchase of unsuitable cable for hoisting purposes during construction at a higher price than that at which suitable cable could be purchased.

The commissioners assumed the responsibility for (d), thus relieving the committee from its consideration.

A few extracts from the findings of the committee will indicate how much foundation there was for these charges:—

"As the impression conveyed by Ald. ———'s charges is that the safety of the whole bridge has been jeopardized by the use of this rerolled steel, the committee feel that this report is not complete without a statement as to what use was made or contemplated to be made of this steel. It has been used as reinforcement in the construction of the retaining wall which forms a part of the north abutment. It has also been used, or is contemplated, as dowels to furnish a bond between successive pourings of concrete in the river piers and springings. It was also used, or contemplated, in the curtain walls of the main piers and pylons of the river arches and as carrier or spacing rods in various other parts of the work. With the exception of the retaining walls where its employment has already been covered by this report, the function of the steel is arbitrary and the material is subject to no definite stresses. In the pylons, the curtain walls are a mere architectural effect and have no structural functions. The steel is used merely to prevent unsightly cracks due to temperature and shrinkage stresses and its section is in most cases far in excess of possible requirements.

The statement has also been made by Ald. ——— that because the Centre Street Bridge is larger than the Mission Bridge, a better grade of material should be used. This is not correct. Mere size is no criterion: in fact, the unit stresses in a large structure may be, and in this case actually are, less than in the smaller ones, and, if anything, a cheaper grade of material might be used with safety."

"Taking up the charges in order, as hereinbefore outlined, the committee submits its opinions:—

A. The question of unsuitable reinforcing material and extravagance in testing the same.

1. Cost of testing. The committee are of the opinion that the cost of testing will not be unreasonable, and that in all probability it will be less than a similar service performed by an inspection company.

2. Quality of steel. The committee are of the opinion that the use of rerolled steel in certain parts of the structure was warranted on the grounds of economy and that in view of the relatively high grade of the material the integrity of the structure has not suffered in any particular.

B. In the matter of foundations of the north abutment or retaining wall. The committee are of the opinion that the failure of this wall, from the causes outlined by Ald. ——— is a very remote possibility, and that the wall is safe against failure from the other possible causes outlined in this report. The committee are also of the opinion that the additional cost of carrying this foundation to rock would not be justified by any extra security so obtained.

C. In the matter of employing consulting opinion. The committee were unable to find that any suggestion to this end was ever made by Ald. ———, or any one else, and they also find that if the understanding existed, as stated by Ald. ———, it was not made public or communicated to the City Engineer.

The committee further are of the opinion that such a course was not justified on the grounds of cost.

After carefully reviewing the statements of Ald. ———, the City Engineer's reply thereto, the record of tests of material, and the plans of the structure, as well as the work itself, and the evidence submitted, the committee wish to state that they can find no reason for the charges and are unable to understand why they should ever have been made.

The committee understands that Ald. ——— could have had access to the plans of the structure at any time, as well as to the stress calculations. As his own statement shows, he had access to the correspondence on file in the engineer's office, and the committee understand that any further information which he might have required would have been cheerfully furnished on request.

From the evidence offered it would appear that the decision to use rerolled steel was submitted to the council and approved without comment from Ald. ———. In his statement to the mayor, Ald. ——— quotes portions only and these not continuous (although his statement would lead to that conclusion) from a letter to the rolling mills, signed by the City Engineer (Appendix 1). Had he quoted this letter in full, together with the reply, the inference would have been very different from what the portions quoted would seem to warrant."

The full report of the committee was filed with the city authorities and with the secretary of the parent society. The commissioners and the City Council adopted the report and thanked the society for their assistance. The council of the parent society also expressed its approval of the manner in which the Calgary branch had handled the matter.

The local society has no apology to make for the action taken. On the other hand, it believes that it has done a valuable service to the profession and the public in establishing this precedent and that if it was more generally understood that charges reflecting upon the ability of engineers in public office would have to pass the investigation of the local profession, that a great deal of unjust criticism would be avoided and the public relieved of a large amount of unnecessary worry.

Sam. G. Porter,
Secretary-Treasurer,
Calgary Branch, Canadian Society C. E.

Better Times

Building permits in Winnipeg, Man., to date this year, exceed by $500,000 those issued during the same period last year.

Elevators in Tall Office Buildings

General Rules for Their Arrangement — Design and Operation of Different Types Worthy of Careful Study

A subject of considerable importance, but of which apparently not very much is known outside of the architect's and designer's office, is the arrangement and knowledge of operation of elevators in tall buildings. With city specifications allowing for increased heights in office buildings, the question of how elevators operate and their most economical arrangement in the building to suit existing conditions, we believe should receive more consideration. The success or failure of a tall office building depends largely on the efficiency of its elevator service to accommodate the tenants during rush hours. No wideawake business man wants an office flat at the top storey of a high building with poor elevator accommodation, even if the building is situated in a desirable business district. It would be well if more people understood how an elevator operates; it might stand them in good stead at a critical time. Some of the problems of the arrangement of elevators in tall buildings and a few fundamental points on the principle of their operation are given here.

Number Required

Practical experience has evolved two theoretical methods for determining the number of elevators required for any building, which in practical use have given very satisfactory results. The two methods are:

1. Allow one elevator for every 20,000 to 30,000 sq. ft. of renting space above the first floor.

2. Allow 1 sq. ft. of elevator floor area to each 1,200 sq. ft. of renting space above the first floor.

The first method is perhaps the better one, as the number of cars is of more vital importance than the size of the cars; for it can be easily seen that two cars of 30 sq. ft. area each would give better service than one car with a floor area of 60 sq. ft. The greatest consideration in determining the number of elevators is to have enough cars, so that there will always be one at the ground floor ready to start on the upward trip. The greater the number of cars the smaller may be the ratio of the cars to the renting area, as with a large number of cars the problem of always having a car at the ground floor solves itself. Where there are less than six cars the ratio should not fall below the maximum of 30,000 sq. ft., while if there are ten cars or over the minimum of 20,000 sq. ft. may be safely used. The character of the tenancy of the building must be considered, for a building occupied by doctors, studios, or retail shops, all having many callers, will require more elevator service than a building occupied by big industrial companies having but few callers.

Location of Elevators

The general location of the elevators must be determined in relation to the typical floor plan rather than to the first floor plan, for here any extravagant use of floor space is multiplied by the number of floors. The elevators must be easy of access to all parts of the typical floors, a central location being the most desirable. However, in many cases a dark corner or the blank party wall is the wisest location, as these spaces are of little value for renting purposes. The bank of cars should be arranged so as not to divide the typical floor, because the renting area should be in an open space in order that it may be rented to a single tenant. This is easily accomplished when the elevators are on the blank party wall, but when they are centrally located greater care is required to prevent them from dividing the floor area into two parts which could not be used advantageously by a single tenant. In case both express and local services are employed the local cars should be stopped at an intermediate floor and space over them on the upper floors rented.

Freight Elevators

There are three methods for the arrangement of freight elevators in office buildings. The choice of a method depends upon the amount of freight that must be handled and the character and the promptness of the service required. These methods are:—

1. The most common and the most satisfactory method is that of having a freight receiving room and one or more freight elevators at the rear of the building, with direct access to the alley or receiving court at the first floor.

2. A more economical method, but a fairly satisfactory one, is that of installing a separate freight elevator at the rear of the building, but without a receiving room at any of the floors. In this case the elevator opens directly upon the alley as well as into the public corridor on the typical floors.

3. A third, and the more economical method, is that of using one elevator in common for passengers and for the delivery of freight, which means that no freight can be delivered during the rush hours, when the car must be used for passengers. Where this system is used it is usually necessary to install a lift to carry freight from the alley to the basement, where it can be sorted and stored until such an hour as it is possible to deliver it to the upper floors. This type of installation necessitates the delivery of small packages which cannot be delayed, as well as the carrying of the building employes in the passenger cars. Many tenants object to entering elevators with delivery men and building employes, so before this system is adopted the interests of the tenants and the character of the service to be given them, must be carefully considered.

Relation of Elevators to Lobby

As already mentioned, the location of the elevators will be largely determined by the arrangement of the typical floor, but their relation to the ground floor cannot be disregarded. The paramount requirement is that the elevators be in direct view of a person entering the building, and they should be as near the entrance as their disposition on the typical floor will allow. The directory board should be so located that visitors to the building will pass it on their way to the elevators, but so situated that those standing in front of it will not block the free passage of others. The mail box and the cigar stand must also be so placed that people loitering at either will not interfere with the free passage to and from the elevators. The entrance to the main stairs should be as near the building entrance as possible and always nearer than the elevators, as any callers to the second floor will walk up and they should not be forced to mingle with or block those passing to and from the elevators. If in any large building there are two entrances there should not be a bank of elevators at each entrance unless the building is large enough to warrant each bank having at least six cars.

Arrangement Within the Bank

The manner of arranging the elevators within the bank may be classed under four schemes, all of which may be varied as occasion demands.

1. The most common method is that of placing the cars in a line perpendicular to the street. Experience tends to show that this arrangement, when more than seven cars are required, is not entirely satisfactory, as with more than this number of cars the distance from one end of the bank to the other is so great that a person missing a car at one end is forced to walk too far to catch a car at the other end.

2. Another arrangement is that of placing the cars parallel with the street. For a small, shallow building this method is very satisfactory, but where a large number of cars are required it is subject to the same criticism as the previous scheme, although if the entrance corridor meets the elevator lobby opposite the centre of the bank this objection is overcome.

3. The fan-shaped bank of cars gives excellent results, but is extravagant of floor space. In perhaps no other scheme are the cars in so direct a view of a person entering the building or so equally distant from the entrance.

4. The U-shaped plan has from the point of service as great advantages as the fan plan, while it has much greater advantages from the point of economy of space and the possibilities which it offers for a good architectuarl treatment of the lobby. To the writer this seems to be the ideal arrangement for a bank of elevators. Upon entering the lobby a person can see every signal light and upon reaching the open side of the U he is almost equally distant from every car, so in case of missing the one for which he had started he has but a few steps to take to reach any other car.

Design of Grilles and Fronts

The design of elevator fronts is largely a matter of architectural design, but the various combinations of materials which may be employed in executing the design to some extent necessitates certain practical considerations as effecting the efficiency of the service. Generally speaking these treatments may be classed under three heads.

1. The first is that in which the entire wall surfaces are covered with marble, tile or terra cotta. When these materials are employed the danger to be avoided is that deep door reveals or heavy pilasters do not obscure the elevator doors, signal lights and indicators from the view of a person entering the lobby. In treatment of this sort the signal lights and indicators should always be outside of the door reveal. When the bank of elevators is parallel to the street this danger is not so great.

2. The next method is a combination of materials already mentioned, with more or less metal grille, in which case care must again be taken that neither pilasters nor columns project too much. The writer has known of several instances where it has been necessary, because of the projection of heavy pilasters, to reconstruct and to extend the signal light brackets after the lobby has been in use for some months. The same defect and the deepness of the door reveals were vital factors among those which necessitated the entire reconstruction of one lobby.

3. An all-grille front is the most desirable, as the contrast of the grille with other parts of the lobby aids in attracting attention to the elevators and a grille lends itself readily to a very flat treatment, thus obviating the dangers of protruding projections of the wall surfaces.

Experience has shown that the door widths should vary but little from 4 ft.; the doors should always be two-fold and, if possible, the two folds should slide in opposite directions, both of these items being of more than temporary moment in the speed and safety with which the doors can be operated.

The size of the cars will, of course, depend upon the conditions of each particular problem, but in few cases should a car have a floor area under 30 sq. ft. and seldom should it be over 50 sq. ft. The cars should always be wider than they are deep in order to avoid delay and danger of accident occasioned by passengers passing one another within the car.

Accessories

It is becoming quite a common practice to install wire glass behind elevator grilles. This does not detract from the appearance of a good grille and has two distinct advantages. The shutting off of the elevator shafts does away with disagreeable drafts which are so common in the corridors of large buildings with open elevator shafts, and the wire glass will often lower the insurance rate. The glass should be a clear wire plate, for and obscure glass is undesirable as the operator of the elevator should be able to see out from his car at all floors.

The signal lights and indicators should be placed immediately over each door and at a height not greater than 9 ft. The numerals and hands of the indicator should contrast in color with the dial, for as elegant as a polished bronze indicator may be, it is of little use, particularly when reflections of light strike its polished surfaces. The simpler the signal lights the better; nothing can be more satisfactory than a sperical globe of not less than 7 in. in diameter with different colored lights in the upper and lower halves, one for "down" and one for "up."

The call-back bell should be placed at the point where the elevator starter will be stationed, and the night bell should be conspicuously located at the end of the elevator bank which is nearest to the entrance of the lobby.

Floors in Cars and Before Doors

The problem of floors in the elevators as well as in front of the doors in the lobby at each floor is important for several reasons. A material selected for these floors must be very durable. It must be non-slipping and must present a surface which can be easily cleaned and which will look well when clean. To fulfill these requirements there seem to be but three materials which can be used satisfactorily: loose rubber mats, rubber tile, or cork tile. Loose rubber mats, although cheaper to install than either of the other materials, are neither so economical nor satisfactory in the long run. Rubber tile and cork tile wear well, are easily cleaned, and require no finished floor under them, while their non-slipping qualities are good.

Regardless of which one of these materials is used, a brass angle should be installed at the juncture between it and the marble or tile floor. The non-slipping surface should run the full length of the elevator fronts, and not just in front of the doors, as serious accidents have occurred to people slipping in making a short turn onto a marble or tile floor upon leaving the elevator.

Types of Elevators

There are two general types of elevators commonly used in tall buildings, namely, electric and hydraulic. The mechanism of a hydraulic elevator consists chiefly of a cylinder and piston with one or more rods connected to a cross-head, which carry the sheaves, over which run the lifting cables from which the car is suspended. Water, under pressure, is admitted by means of suitable valves, which cause the piston to move from one end of the cylinder to the other and back again. Motion is transmitted to the elevator car by means of the sheaves mounted on the cross-head, which carry a lifting cable. The cylinder may be either in a vertical position alongside the hatchway or in a horizontal position in the basement of the building.

In some cases the valves of a hydraulic elevator are operated by a hand rope passing through the car and over small sheaves at the top and bottom of the building and connected with the main valve in the basement. By pulling this rope down, the valve is opened and the car will ascend; by pulling the rope up the car is caused to descend. Two balls are attached to this hand rope, one near the top and one near the bottom, which serve as safety devices. The balls come in contact with the top or bottom of the car according as it is going up or down, and being carried along they move the cable, thus actuating the valve and bringing the car to a stop.

Another type of safety device often employed on this type of elevator is a set of safety clamps under the control of a speed limit centrifugal governor which causes the clamps to grip the guides and thus hold the car. This safety governor is operated by a small cable connected with the car and moving with it, which passes over the sheave pulley of the governor.

Other methods used for manipulating the water valves are by running ropes and standing ropes, either of which may be operated by means of a lever or wheel in the car. These devices operate a small pilot valve which, when opened, admits water under pressure to a small cylinder with a piston connected to the main valve stem. This actuates the main valve, which in turn, by its movement, closes the pilot valve. The opening of the pilot valve, and therefore the main valve, is directly proportional to the distance of the lever in the car from its central position. This central position is the position in which there is no flow of water either into or out of the cylinder. Moving the lever too quickly to a central position when the car is moving at a high rate of speed arrests it with a sudden jerk. The water pressure generally used for operating hydraulic elevators in ordinary buildings is from 150 to 200 lbs. per square inch. In high buildings where speed service is required, higher pressure is employed.

Another type of hydraulic elevator is the plunger type, one in which the car is placed directly on top of a plunger or piston. A cylinder is set vertically in the ground under the centre of the car, and the length of it is slightly greater than the travel of the car. In this cylinder is a plunger which carries the car. Water, under pressure, is forced into the cylinder, which lifts the car and is allowed to run out at the top when the car descends, so it is always full of water. The usual diameter of a plunger or such a type is 6½ to 7 inches, and it is constructed of lengths of polished pipe joined together with an internal sleeve and has its lower end closed. The top of the cylinder is arranged with a packing gland through which the plunger works up and down. Such a type cannot be overbalanced because the power acts only during the up stroke.

Overbalancing, or having a counterweight heavier than the car, is employed on electric elevators. It permits the use of smaller motors. Electric elevators are operated either by alternate current or direct current motors. Current is transmitted to the motor by an electro-magnetic controller, operated through a switch in the car. The brake on electric elevators may be either mechanical or electric. In an electro-magnetic control the brake is set by a spring or weight and is released by a solenoid. Limit stops, or lower limits of travel, are usually buttons or knobs placed on the shipper rope against which the car strikes and automatically shuts off the power. Such buttons are not sufficient protection in themselves. They are apt to slip or break. The more common form of limit stop is a gear wheel working loosely in an extension of the drum shaft. Should the car over-run its limit either on the up or down trip, jaws on the hub of the loose gear engage with jaws fastened to the drum shaft causing the loose wheel to rotate. This sets in operation the gear, which turns the shipper sheave, thereby reversing the motion of the elevator. Considerable power may be wasted in operating electric elevators by careless handling, that is, in making unnecessary stops and starts, as the power consumed by the starting torque of an electric motor is many times the power used in normal operation.

Cast Iron in High Speed Engines

In modern high-speed engines cast iron is the only metal which has proved satisfactory for the construction of such parts as pistons, piston rings, cylinders, and liners. The chief requirements are good running properties and resistance to wear. Up to the present time the mechanical properties have been regarded as of secondary importance on account of the thickness of metal used, but in the light of modern tendency towards the cutting down of weight it is possible that stronger irons will be in demand in the near future. Good running properties and resistance to wear are often confused by engineers. The two properties are undoubtedly connected with each other, but they are not identical, and cast irons are often condemned "because they do not wear well," when what is really meant is that they do not develop good working surfaces in use. It is impossible to correlate the wear with hardness. The internal structure has an important bearing on the resistance to wear. Cast iron consists of graphite plates set in a matrix of ferrite, pearlite, phosphide and cementite, in which ferrite predominates when the iron is soft and perlite is in excess when the iron is hard. Microscopic examination of worn liners shows that pitting has been caused by the removal of certain grains under the abrasive action of the rings assisted by the vibratory motion of the piston. This pitting has often been erroneously ascribed to the dislocation of the graphite plates. At the same time as this dislocating action is taking place, a kind of polishing in bas-relief is being brought about by the action of the dislocated powder suspended in the film of oil. Microscopic examination of worn surfaces often reveals the harder phosphide eutectic and the cementite grains standing in relief without the action of etching. Further, the continued rubbing action gradually converts the surface of the iron into the vitreous state, when the iron becomes what is commonly known as "glazed," and it is a well-known fact that this action may take place to such an extent that the surface becomes so hard that difficulty is experienced in filing it.

Grouting by the Pneumatic Process

An Economical Means of Stopping Leaks in Driving Tunnels and Sinking Shafts in Water-bearing Ground

IN tunnelling or sinking shafts grouting has demonstrated its effectiveness and has been the means of a great saving in the cost and maintenance of pumping machinery and in prospective profits. Contractors have lost thousands of dollars in tunnelling through bad ground when a knowledge of grouting methods might have been the means of causing them to adopt such a system and would have saved them considerably. There are attractive possibilities for grouting in tunnelling a heading which passes through water-bearing ground; but the field is not confined to tunnels and shafts, there are splendid opportunities for it on the solidification of dam sites. To obtain success with the process, however, a thorough understanding of and strict attention to all details are necessary. The process is doomed to failure if entrusted to men not familiar with such details. The following information on grouting in wet ground tunnelling, and the methods of filling cavities and cutting off water flows, is based on the experience of James F. Sanborn, division engineer of water supply, New York City, on the Catskill aqueduct, as given by him in a series of articles in the Engineering Record.

The purpose of grouting is to force a mixture of sand, cement and water, into the space to be filled. In view of the importance of securing a thorough job of grouting and the eliminating of leakage under pressure, careful consideration of the geology of the rock, the distribution, and the nature of the opening must be made, and the methods of grouting adjusted to meet such conditions.

Equipment

Considerations of the best method of drilling and placing holes for grouting, the proper consistency of the grout mixture, the best cement to use, what injection pressure should be applied and the best means of producing and controlling the flow of grout are among the matters most vital to the success of the process.

The best equipment to use in any case depends very much upon the pressure necessary to make the grout travel, and the consistency of the mix best adapted to the kind of openings to be filled. If a considerable yardage of grout is required, an equipment with large capacity is desirable, while a smaller quantity placed slowly under high pressure may demand a different equipment to secure the best results.

Grouting is often done by pouring through pipes arranged in such a way as to secure the necessary pressure. Commonly, however, more pressure than that afforded by the head of grout alone is required. The equipment ordinarily used may be classed as follows:

1. Reciprocating pumps furnishing a continuous flow with independent means of mixing the grout.

2. Grouting tanks, which are of two classes—(a) paddle mixing and air ejecting and (b) air mixing and air ejecting.

The paddle mixing and air ejecting type of grout tank has been extensively used on shield-driven tunnels and elsewhere. They have many advantages, and are economical when large quantities of grout are to be placed, as in grouting dry packing. The moving parts and stuffing boxes, however, wear rapidly, while the paddles and shaft become coated with grout. As the machines receive very little care in a tunnel, they wear out fast.

In grouting the shafts and pressure tunnels of the Catskill aqueduct the equipment consisted of tanks of the Canniff type, in which the grout was mixed, a batch at a time, and ejected by compressed air power through a heavy wire-wound high pressure hose, attached by fittings to pipes previously secured in position at the point where the grout was to be introduced; 2-in. or smaller grout pipes and 2½ or 3-in. hose was commonly used.

The compressed air is made on most contracts by air compressors of large capacity, which are part of the plant used while driving the tunnel and furnish air at pressures from 80 to 100 lbs. per square inch.

Canniff Grout Tank

The chief advantage of the Canniff grout tank is that it has no moving parts to be cut out by grit, leak air, and delay the work for repairs, as happens in the case of pumps. This advantage is greatly in favor of the grout tank, particularly for tunnel work, where the darkness and distance from the shop and supply room make renewals slow and expensive. The time lost in making renewals with this tank is very little, as only the gasket of the door and the valves are liable to wear. Its compactness and light weight are great advantages, as the floor space occupied by a tank is very small, not over 4 square feet. The Canniff tank is well adapted for handling grout rapidly. As high as 1,500 batches or 115 cubic yards of grout have been placed in one day of three shifts by a pair of tanks. A small force operates the tanks and no high-priced men are required for repairs or operation. Either rich or weak grout can be used, and the tank is adapted for low as well as for very high pressure.

A disadvantage of the Canniff tank is shown when used for high pressure work, when the grout is discharged very slowly into fine seams, taking a long time. In such cases the cement has time to settle out of the mixture and clog the openings. However, as very thin grout should be used in such cases, the difficulty is not very serious practically.

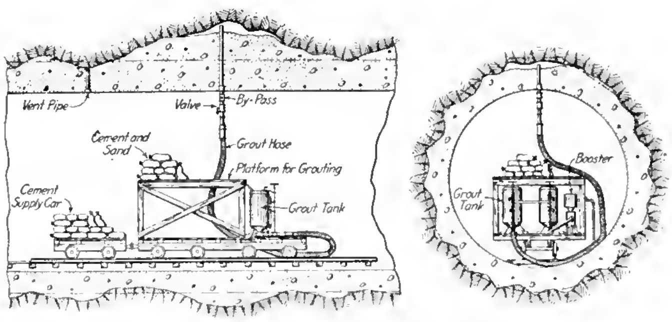
Care in Operation

Unless great care is taken with any type of grout tank to shut off the discharge valve, the instant the last of the grout leaves the tank, an after-blast of air follows, which has a bad effect in stirring up the grout. The air tends to collect in the space to be grouted and is displaced with difficulty by the cement. The men operating the tanks, however, become very expert in controlling the discharge. Both the air-mixing tank and the paddle-mixing tank discharging a single mixed batch by compressed air pressure, are well adapted to mixing and discharging a large quantity in a short time, especially into a large open space which takes grout easily. In work requiring high pressure, using thin neat grout, the results with the Canniff tank are very good. The grout commonly used is 1:1, but grout of a consistency of 1 cement to 2 sand is often mixed and discharged without trouble.

As in all grouting, for filling large cavities thick grout is placed, while for success in filling very fine seams, exceedingly attenuated mixtures are employed —5 lbs. of cement and 25 gals. of water in the early stages of injecting the grout—with the idea that the water will carry the cement as far as possible into the fine seams and avoid blocking up close to the drill hole. This is a very important point if complete success in the process of shaft sinking is to be attained.

Grouting Car

The grouting car and equipment generally used are shown in the figure. For the low pressure work two grout tanks are usually mounted on a car provided with a platform for handling the cement and sand, which is emptied directly from the bags into the grout machine (a bag of sand and a bag of cement to each batch), although two bags of sand are sometimes used to each bag of cement in grouting dry packing. The water is commonly added by hand by means of a bucket from barrels on the car or from the tunnel invert, although some contractors provide water tanks with an overflow at a designated height. These water tanks, of light gauge steel, are mounted on the grout tank and are emptied by a three-way valve. A belted centrifugal pump keeps a continuous stream of water circulating to supply the tanks, but does not always prove as reliable as a small air-driven reciprocating pump. The sand and cement are transported on flat cars by the tunnel mules or trolley motors to the grouting equipment and handled by hand. It is essential for the rapidity of low pressure grouting work that plenty of material be always stacked up on the grouting platform, as the operation is so rapid that the stock is quickly exhausted unless constantly renewed.



The General Layout of a Movable Grouting Plant in a Tunnel.

Plant for High Pressure Work

For the low pressure grouting, the air supplied by the compressors on the surface is usually found adequate, but for high pressure grouting air at 300 lbs. pressure per square inch is used on account of the high ground-water pressures, often over 100 lbs. per square inch being encountered.

The high pressure grouting equipment consists of a car, smaller than that used in the low pressure grouting and carrying one or two grouting tanks. The amount of grout used in the high pressure operation is only about one-tenth of that placed in the low pressure operation and, furthermore, it takes much longer to discharge each batch.

In addition to the grout tank, the high pressure grouting car often carries an air pump or booster operated by compressed air from the tunnel plant at 100 lbs. pressure, delivering air at 300 lbs. pressure to the grouting tank. Another grouting tank is commonly mounted on the car, but is used only as a receiver for the high pressure air. As in the low pressure operation, the grout is discharged through a wire-wound hose from the tank to the grout pipe set in the concrete or rock. Each pipe to be grouted is provided with a nipple and special plug cock to which the hose is attached by a union.

A wet tunnel is always slower and more expensive to drive than a dry one, as it is more difficult to keep the men working under a wet roof, and the necessity of pumping the water is an additional expense.

Filling Cavities

The space over the concrete arch in rock tunnels cannot be completely filled, as the soft concrete packed into the key settles away by gravity, leaving a void as much as 2 or 3 inches high above the concrete arch. Places where the rock breaks high are filled as completely as possible, and afterwards completed by injecting grout in the form of mortar. Experience has shown that this grout is very effective; no voids of considerable size are left. Where dry packing is used in bed ground which requires a support of permanent steel ribs and lagging, grout is injected to fill the spaces between the pieces of rock forming the rubble or cyclopean concrete.

Drains and drip pans placed between the rock and the concrete lining to waterproof the soft concrete against the incoming water from rock seams, is another illustration of that class of cavities of large size where thick mortar grout is used as a backing for the concrete. In this case the water is discharged through weep pipes through the freshly placed concrete to prevent the water, which is frequently under high pressure, from washing and disintegrating the lining before it has set. When it is necessary to shut off this water after the concrete has hardened, grout is injected to fill the drains and pans.

The grouting of large cavities requires the use of 2-inch pipes, through which the grout is injected. They must be carefully placed to lead the grout to the lower part of the cavities. Vent pipes leading from the summits of the cavities are placed during the period of concreting to permit the escape of air and water as the grout is injected. These vents further serve the purpose of telltales to show when the cavity is completely filled with grout.

For filling cavities of large size, sand and cement grout in a mixture of one part of each is used, mixed with a quantity of water just sufficient to produce a grout not too thick to be easily pumped.

Dry and Wet Cavities

Work of grouting large cavities divides itself under two heads. First, grouting dry cavities displacing water; and, second, grouting wet cavities displacing water. When both wet and dry cavities lie in close proximity and are connected, the best results are obtained by grouting the dry cavities first and permitting the grout to set before attempting to fill the wet cavities. If the wet cavities are grouted first, the water ordinarily shifts to some near-by dry cavity, thereby multiplying the number of wet cavities to be grouted.

Grouting Dry Cavities

When considerable stretches of tunnel are to be grouted, the usual method is first to grout the space over the arch and the dry packed stretches, using an air pressure of about 40 lbs. to the square inch, and, after this grout has set, to make a second trip through the tunnel to complete the grouting of any spaces over the grout first placed and also to grout all pipes and pans carrying water.

The first, or low pressure grouting, employs thick 1:1 sand grout, while the second, or high-pressure grouting, employs only neat cement grout injected generally under a pressure of 300 lbs. to the square inch. Entirely different methods are used in the two processes and a special plant is required in each case.

Rock Seams

The grouting of rock seams outside of a tunnel lining is, perhaps, the most difficult type of grouting. In the first place, it is hard to drill holes which will give adequate access of the grout to the rock seams. In the drilling operation, even though the hole encounters the crack in the rock which carries the water, the pounding action of the drill is liable to calk the cavity with powdered rock, so that when the grout pressure is applied it will not enter freely,

As a rule, there is a chance to inject grout into rock seams, and where the chances are poor, no definite rule can be given. The inward leakage is, in a sense, an index of the amount of grout that can be injected.

For injecting grout into rocks which show a seepage, but no considerable flow of water, three arrangements of grout piping are tried.

1. Drilling in enough deep-seated pipes to collect the water and protect the mortar from washing.

2. Putting in a drip pan with independent additional deep-seated pipes to the rock seams.

3. Using drip pans alone, grouting them with thin grout, then draining the pan and filling it with thick grout to complete the backing.

Experience seemed to indicate that the second method is a little the best, although in most cases the third method gives complete satisfaction in cutting off water.

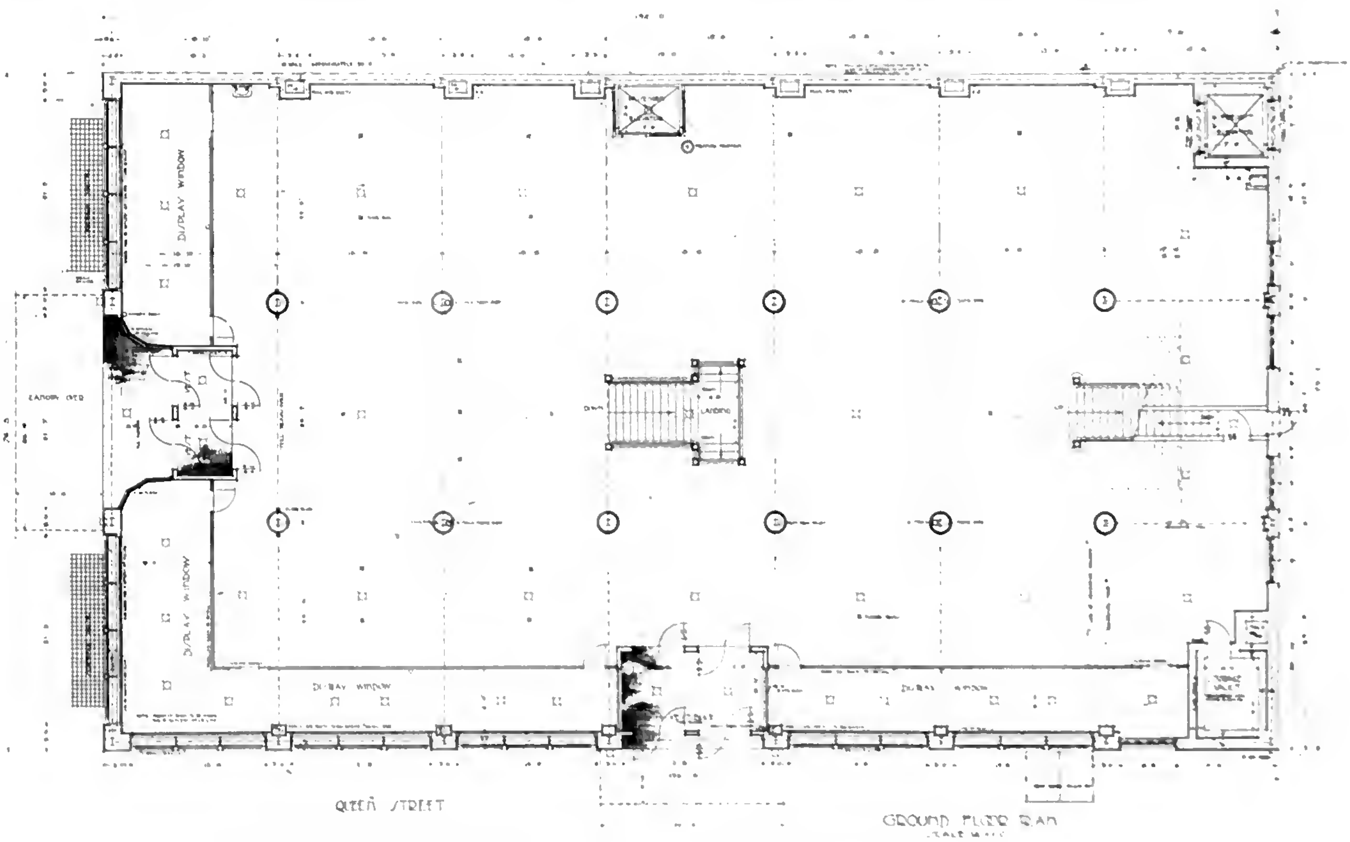
New Department Store at Brantford, Ont.

THE cut herewith shows the ground floor plan of a large department store recently erected in Brantford, Ont. It was built by W. C. Livingston on the corner of Queen and Colborne Streets and has been leased to the E. B. Crompton Company, Limited.

The store is of steel construction with reinforced concrete foundations and footings. The exterior walls are brick with artificial stone window sills and caps and cast iron cornices and copings. It is four storeys and a basement high and has main entrances on both Queen and Colborne Streets. The Colborne Street entrance has a wrought iron marquise canopy over the door. The entrance vestibule is approximately 15 feet square, while the Queen Street vestibule is 16 ft. x 9 ft., both vestibules are tile floored and have double plate glass doors.

The show window on Colborne Street is 9 ft. wide, and on Queen Street, 6 ft. wide. The window bays are finished in hardwood with wood and muranese glass back, fitted with sliding doors. The bays are lavishly lighted with large units.

The enquiry office is situated at the foot of the basement stairway in the centre of the store. There is also in the basement a parcel room, stock and shipping rooms, storage, cloak rooms, and the fuel and boiler rooms. The whole of the ground floor is taken up by store space. A 20 ft. mezzanine floor runs around the end of the building furthest from the Colborne



New Department Store, Corner Queen and Colborne Sts., Brantford. Angus and Angus, Architects.

Street entrance. The cash registers and general offices are located on this mezzanine floor. The first floor, with the exception of the rest room over the Colborne Street entrance, is given over to store space, while a grill room, dining room and kitchen are located on the second floor over the Colborne Street entrance. At the opposite end of the building on the same floor are public lavatories. The third floor is taken up entirely by store space. The building is equipped with both passenger and freight elevator service, besides having a flight of stairs at the centre of the building. The store is modernly equipped in regard to lighting, heating and ventilation. Angus & Angus, Sudbury, Ont., were the architects on the building.

New Great Northern Railway Station at Vancouver, B. C.

MESSRS. Grant, Smith & McDonnell, contractors for the new Great Northern Depot now being erected at Vancouver for the Great Northern Railroad Company, on April 14 awarded to Palmer Bros. & Henning, the contract of driving over 500 tall piles in the filled-in area of False Creek, lying east of Main Street, to support the foundations of the new structure. To-day work on the concrete piers is well advanced, and at the rate the mixture is being poured it will not be long before a start is made on the sub-structure. Mr. E. B. Ford, chief engineer for the Great Northern Company at Vancouver, has the details well in hand, being assisted by Mr. Fred L. Townley, the Vancouver architect, whose plans met with the approbation of the management at St. Paul, Minn. Trade tenders for most of the sub-contract work have been allotted, and the material is being assembled so that there may be no delay in connection with any department.

The new station will occupy a site on Park Lane 300 feet back from Main Street, and will be in line with the Canadian Northern Railway station, to be built in the near future. The depot will be a handsome structure of two storeys, with the terminal facilities on the main floor and offices above, the material selected being brick over reinforced construction, with granite base and terra cotta trimmings and cornice. The frontage will be 235 feet, with a depth of 54 feet. The baggage room wing, forming an "L," will extend back 210 feet, and will be one-storey in height.

The main waiting room, 34 feet high, will have two entrances from the street and two opening upon the train concourse, with a carriage entrance at the side. The room will have a terazzo and marble floor, marble base and ornamental plaster ceiling. Opening therefrom will be the men's and women's retiring rooms, toilets, immigrants' room, parcel and news, telegraph and ticket office, exhibition room, Customs office and depot master's office, baggage room, mail room and express rooms.

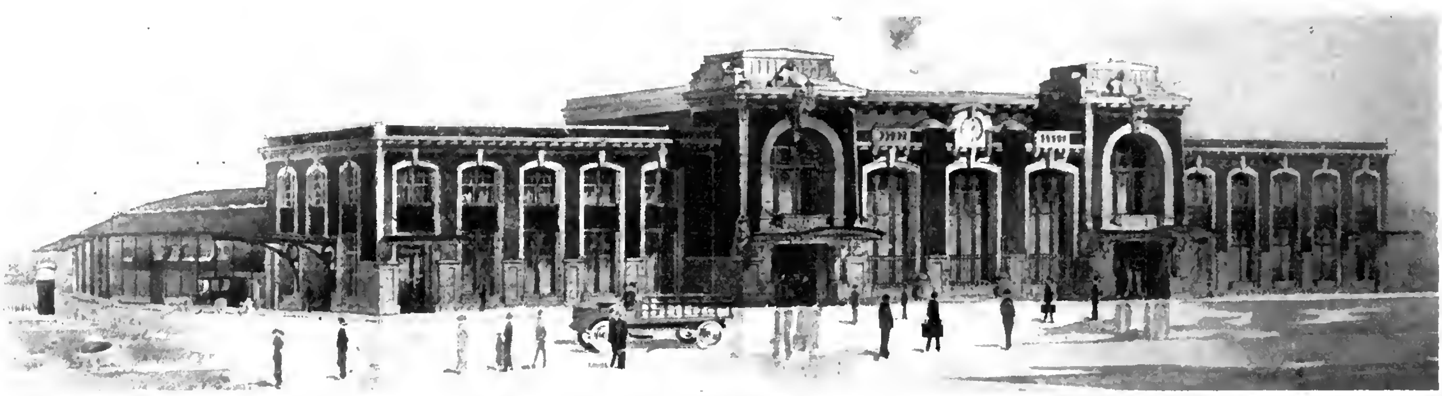
The passenger concourse will be glass-covered the full length of the building the width being 25 feet. There will be eleven sets of tracks, the train shed roofs extending a distance of 700 feet.

Heat will be supplied from an isolated power plant, pipes being brought into the main building through a tunnel. In all probability the electric light plant will be located in the same building.

Porcupine Good Roads Association

A Good Roads Association has been formed in the Porcupine district and already a policy has been outlined in regard to the treatment of traffic conditions in and around the gold camp. Acting through this association a number of prominent business men in the Porcupine district will approach the government in an effort to obtain assistance in improving the present highways and extending them.

The London Concrete Machinery Company, London, Ont., have secured contracts for the following equipment: City of London, one ¼ yard batch mixer for sidewalks; Guelph Department of Agriculture, one ¼ yard batch mixer and one cement drain tile machine; R. H. Barker & Co., Newmarket, Ont., one ¼ yard batch mixer; Schultz Brothers & Co., one ½ yard tower hoisting equipment; Westinghouse, Church, Kerr Co., of New York, one ¾ yard tower hoisting equipment to be used on construction work in Windsor; Shawinigan Water & Power Company, one No. 10 London elevated drum paving mixer; Morrison Brothers, Pense, Sask., one 1/6 yard batch mixer; city of Ottawa, one London elevated drum side discharging batch mixer with rotary delivery spout.



Handsome Building of The Great Northern Railway Under Construction on Reclaimed Area of False Creek Tide Flats, Vancouver, B. C.

The Benefits of Town Planning

The Need of a Carefully Thought Out Scheme to Provide Co-operative and Economic Conduct of all the Varied Interests.

By W. R. Davidge, F.S.I.*

BEFORE entering upon the discussion of accepted town-planning principles, it is well to realize that the term "town planning," embracing all communities large and small, is a very English one. In the United States and Canada the universal description of the same thing is "city planning," which seems at first even more inappropriate, until it is remembered that in America a community may be a "city" even if it has only 500 people in it.

With us the cities of London and Westeminster and our other cathedral cities are of so ancient a foundation that it gives us somewhat of a shock to find that many of our Colonial towns have springing up around them scores of such "cities." Melbourne, for instance, is surrounded with numerous growing suburbs, nearly a dozen of which are dignified by the name of "city." So general has the practice become that, by special enactment of the State Government, it is now possible to adopt the name of "city" as soon as the population reaches 20,000. The term "town planning," however, fairly correctly describes the methods so far adopted in England, as contrasted with the expression "town building" ("stadtebau" or "construction des villes") prevalent on the Continent. In this country, under the Act, our effort is principally directed to planning the land around our towns, and so far the architectural or "town building" side has hardly been touched. This variation in nomenclature expresses in another form the varying ideals and national characteristics of "town planning" or "city planning" as understood in the various countries of the world. It is well that this divergence of national outlook should be appreciated before we proceed to discuss "accepted principles, by whom accepted, where and why accepted." There has in the last six years been an amazing wealth of literature and such a mass of reports on various phases of the subject that it is somewhat difficult to disentangle the exact facts as existent. In Great Britain the creed of town planning may be expressed briefly as "more air," more accessibility, more attractiveness!" or in other words, health and social well-being, particularly as applied to the prospective building land around our towns. In conjunction with this there is at the same time, so far as private estates are concerned, a very evident effort, in some cases almost a straining, after the picturesque. In modern garden suburbs, equally with the mediaeval town, the effort after picturesque features has secured many charming examples, which are a welcome relief from the drab of the everyday town.

Municipal surveyors, as a body, fully appreciate the great possibilities of town planning from the health and amenity point of view, but so far, at any rate, the "picturesque" is entirely in the province of the private owner and his architect, aided or retarded by the jerry builder. In Paris the desideratum is more often the spectacular or monumental art of "construction des villes" in the grand manner. In Berlin "der Stadtebau" represents the same ideal of imposing public buildings and monumental-looking structures which are in reality tenement dwellings. As a well-known German professor said in 1910 at the Royal Institute of British Architects' Conference:—"What we in Berlin try to do is, at all times and to the utmost of our power, to impose upon the stranger!"

American cities mostly regard city planning fom one of two ideals, either the "civic centre" ideal or the "rapid transit" ideal, both of which our American cousins would describe as "good business propositions," and business is the keynote of all sound proposals.

Colonial towns are, as is well known, mostly laid out (for the convenience of the surveyors) on north and south lines, with all streets at right angles, and, until quite recently, this tendency has manifested itself in the lay-out of practically all towns which have had to be developed rapidly, generally in the absence of any special natural features.

It has been necessary in nearly all cases to peg-out and sell plots of land rapidly, and the Colonial surveyor in laying out a town has almost unconsciously come to regard it as "cutting up so many sections," simply and solely "land jobbing." The idea of a community deliberately moulding its own growth to its future needs has so far hardly been realized.

The Need for Town Planning

One thing that stands out clearly, though, in the maze of these different national and local characteristics is the paramount need for some form of town planning.

Whether one sets out with the purpose of sweeping away slums or of providing for the future growth; whether one is an enthusiast for parks and open spaces, or merely desirous of the commercial advantages of rapid transit and business facilities, all nations and nearly all communities are agreed that, if it is reasonable to plan the alterations to a house that one intends to inhabit, it is still more desirable to plan the town and its extension; hence the first general principle which we can all accept is the universally recognized need for town planning.

Our first accepted principle, then, is:—A town plan is necessary.

Following on this, however, must come the recognition that such a town plan is not a stock article, but must be made to the measure of the district. National characteristics and aspirations, as we have already seen, have resulted in widely varying national conceptions on the subject of town planning, and localities vary as widely in their views as to development, particularly as to the kind of development which is suitable for their town. A town's plan must be its own.

From the point of view of protection of property-owners in residential districts, some form of restraint as to the location of commercial buildings is clearly necessary, and, so far as the Act has gone, the constitution of separate areas for factory and commercial purposes has been carried out without difficulty.

As so many of us are aware, however, the real test of such restrictions will be felt in the next generation. With the continual growth and prosperity of a town the commercial area will surely expand, and unless

* Before the Surveyors' Institute, London.

adjacent space is provided for expansion the business side of the town will necessarily overflow into the residential quarters. In all old centres this alteration of use is continually before our eyes. In New York, within the last few years, business which formerly was done in Twenty-third Street has now moved up as far as Forty-second Street, and an entirely new shopping district created.

Even in London the one-time quiet residential Hanover-square is rapidly assuming a commercial character, and the once peaceful quiet of Soho Square has long been broken into by the pickle factory. Such changes are in the nature of things, and, however hard and fast the restrictions of a town-planning scheme may be drawn, it is evident that unless the plan itself also provides for extension mere legal restrictions will have no more force than the out-of-date paper restrictions of many one-time high-class residential estates, more honored in the breach than in the observance.

Provision must therefore be made for the gradual expansion of commercial districts.

The phenomenon of the overflowing of business into the residential areas of a town is constantly before our eyes, but it is curious to note that in nearly all towns, no matter how old, the heart of the business community still has its nucleus in the area of the original settlement.

Increased Height of Business Premises

It is the endeavor to crowd as many office buildings as possible near this commercial centre that has created the "skyscrapers" of Lower New York. This tendency towards increased height of buildings in commercial centres is equally noticeable in such cities as Sydney, Melbourne, Winnipeg, Vancouver, and even in comparatively small cities like Regina. There is everywhere a tendency to increased height of business premises.

Control of Building Heights

The New York authorities have given much consideration to the important question of regulating the height of buildings. In Lower Manhattan there has for many years been a growing tendency towards the erection of tall "skyscrapers," mostly office buildings. The excuse for this has been the limited area available in the older commercial quarter of the city, but the real purpose has in many cases probably been for advertisement purposes. The Woolworth Building at present easily holds the record.

Limits of Height

The limits of height of buildings in various cities are at present as under:—

London.—80 feet.

Paris.—In streets less than 40 ft. wide, street width plus 20 ft. In streets over 40 ft. wide, 58.64 ft. plus ¼ (width—40 ft.).

Berlin.—Maximum 72.2 ft. (22 metres).

Boston.—District A. 125 ft., or 2½ times width of street. District B, 100 ft., or 1¼ times width of street. (Buildings over 80 ft. only allowed on streets over 64 ft. wide.) Special restriction to 70 ft. on blocks adjoining State House.

Washington. — Pennsylvania Avenue. — 160 ft.; other business streets, 130 ft., or street width plus 20 ft.; residence streets, 85 ft.; or streets over 70 ft. wide, street width minus 10 ft.; streets 60 ft. to 70 ft., 60 ft.; streets less than 60 ft., street width.

Other American Cities.—Baltimore, 175 ft.; Chicago, 200 ft.; Los Angeles, 150 ft.; Salt Lake City, 125 ft.; Toronto, 130 ft.

New York.—Limit of height of apartment and tenement houses, 1½ times street width.

The New York Commission recommend the limit of height for all buildings within 100 ft. of Fifth Avenue to be 125 ft., and that the general restriction for residential districts should be 1½ times street width, i.e., for 60-ft. streets height would be 90 ft., and for business streets twice street width with maximum of 300 ft. A number of American cities, including Baltimore, Milwaukee, Minneapolis, and Los Angeles, have in recent years established separate residential and industrial districts.

Trade Facilities

The provision of efficient and up-to-date means of transit is one of the most important items in the development of towns; yet, strange as it may appear, this all essential detail is omitted from the calculations of many would-be town-planners.

In America, where distances are so immense, the transit question inevitably bulks largely, but especially in recent years American towns have given more and more attention to the problem of the quick distribution of passengers from the outlying districts to and from the central or business portions of a town.

"Rapid transit" is therefore one of the first considerations of our American cousins in considering the problem of town development, and it is indeed strange that we in this country are only dimly beginning to realize this in our struggles after new and improved arterial roads. Main roads and motor traffic are, however, only one part of the problem, and in America many experts are giving their attention to the solution of the transit problem as a whole.

It is naturally found that property in the neighborhood of a "rapid transit line" develops more rapidly than other parts of the town, and if only one such line exists it will naturally absorb the greater part of the normal growth of the town.

The question of the amount of traffic to justify the construction of a tube railway or tramway subway will depend upon local geographical and commercial conditions, but it is a curious fact that, so far as this country is concerned, no town with a population of less than half a million has ventured to introduce a tube railway or electric "rapid transit" line.

Arterial Roads

For many people town planning begins and ends with the planning of roads, and there can be no gainsaying that the main roads into and out of a town are the skeleton on which the plan will hang together. They may, in some instances, be the "bone of contention," but all will be in agreement with the general principle of fixing the routes needed for new main roads, including, of course, reasonable circumferential and cross-roads. The routes for arterial roads should be laid down at an early stage in the town plan, and definitely secured or sterilized from other uses.

Roads and Road Widths

Much discussion and many conferences during the past six years have taken place on the question of road widths and construction, especially perhaps as to the allocation of space for various classes of traffic.

The general principles arrived at may, I think, be reasonably summarized as follows:—

To secure easy and rapid transit—

(1) Classification of roads is desirable.

(2) Provision for fast and slow traffic (fast traffic

should not have to slow up for cross-traffic), and separate tracks for tramways.

(3) Sufficient width of roadway for the traffic, but not too wide to be maintained.

(4) Sufficient width between buildings for all future purposes.

To secure the amenity of the highway—

(1) Good views from the road—preserving view points.

(2) Good views of the road—trees, but not too thickly planted.

(3) Pleasant walks alongside the road—grass and trees where possible.

(4) Pleasant halts by the way—an occasional village green or open space.

It should be borne in mind that estate development is not necessarily an object of main roads.

And in the lay-out of estates the principles laid down in my paper at this Institution six years ago still hold good, viz.:—

(1) Main routes must take the direction required by the traffic and contour of the ground.

(2) Geometrical planning is not necessarily satisfactory.

(3) Long straight streets, when adopted, should have a definite motive.

(4) Slight curves or irregularities in frontage lines and building lines may often be adopted with advantage.

(5) Line of sight should in most cases be restricted within reasonable limits.

Relaxation of By-laws

A very important point on which most people are now agreed is, that, while it is desirable to have a minimum distance between the building lines, a hard-and-fast by-law width is undesirable whether it be 40 ft. or 50 ft. (or 66 ft. as in the Colonies).

The power to fix building lines is important.

The width of macadam or roadway paving provided should be dictated by the use to which the street is put.

In residential streets the remaining width available may reasonably be devoted to grass margins and tree planting.

Compulsory Town Planning

Another point which has been much discussed is as to the desirability or possibility of making town planning compulsory, and it is probable that all will be agreed that the time has not yet come for compulsory town planning.

In Massachusetts and other States the appointment of a town-planning board is compulsory for all towns with a population of over 10,000. In Canada the Nova Scotia Town Planning Act, passed in April, 1915, makes town planning compulsory for the whole of Nova Scotia, and this experiment will be watched with interest.

Progress in the Colonies and India

The other Canadian provinces which have adopted special town planning Acts are New Brunswick and Alberta in 1912. It is probable that the remaining provinces will shortly follow suit, and the same may be said of the various Australian States and the New Zealand Government. In India the Bombay Government has already led the way in this respect.

American Ideals

American city planning may be divided into four phases:—

(1) Rapid transit (already touched upon), which may be described as the engineer's ideal.

(2) The civic centre, which may be described as the architect's ideal.

(3) The provision of diagonal avenues and parkways.

(4) The provision and linking up of parks, and the scientific distribution of children's playgrounds.

The Civic Centre

The value of magnificent monumental buildings, in encouraging a sense of civic pride, is everywhere appreciated, and this, no doubt, is the reason for the American thirst for civic centres. The idea of an architectural conception or ideal, however, is unfortunately in most cases limited to monumental enterprises of this type which are little likely to be carried into effect, and the cost of which would be almost prohibitive. It is strange that such an eminently practical people as the American should devote so large a portion of their "city planning" programme to the provision of these costly civic centres, while allowing miles on miles of rectangular blocks and hundreds of five-storey tenements to be built in all directions without a murmur. Business centres and subsidiary centres will nevertheless form themselves in every town.

Diagonal Avenues and Parkways

It is a remarkable commentary on the rectangular block system of development everywhereto be found in the United States that, almost without exception, planning commissions are reporting in favor of the construction of new diagonal avenues across the rectangular system to provide access in a radial direction to and from the centre or business portion of the various cities.

The rectangular system of lay-out has generally proved quite satisfactory so long as the town remains of limited size, but once the town develops beyond the original square mile or so some form of diagonal communication becomes a necessity, and the improvement plans that are being prepared by practically all American cities are realizing this essential point. Philadelphia has already spent some millions on the Fairmount Parkway," which is nothing more or less than a diagonal of this description. The improvement plans of Brooklyn and scores of other cities in the States, and even so far afield as Santiago in Chili, all show the now generally appreciated need for diagonal routes.

The Linking-up of Parks

The linking-up of parks by a system of parkways or tree-lined avenues is also a well-recognized part of American city planning.

The South Park system of Chicago is an excellent example of what can be done in this direction; but Minneapolis, Kansas City, and many others, are all examples of the same tendency. In fact, there is a danger that the new fashion of city will be almost as stereotyped as the old.

Provision of New Parks

The need for parks in the outskirts to provide for the growth which must come is everywhere realized, and during the last few years there has grown up a system of acquiring such parks for the public by means of a special rate or levy made by the Park Commissioners on all land in the neighborhood, the value of which will be improved by the presence of the park.

In this way many large areas have already been secured at Kansas City, Minneapolis, and elsewhere at little or no direct cost to the ratepayers, and it has been found in practice that the betterment in value of the property in the neighborhood of the park more than recoups the owners for the small special rate they are asked to pay.

We may well ask ourselves whether we should not now be securing further and larger breathing spaces around the built-up area of all our large towns, and we might perhaps at the same time take a leaf out of modern American practice in order to relieve the ratepayers from any unnecessary burden.

The Preservation of River Banks and View-points

In America it is now a well-recognized practice that river banks and valleys should as far as possible be preserved for park purposes, and that view-points and hill-tops should be similarly preserved.

Such a course is desirable not only from the point of view of amenity, but to secure the stream from contamination, and, at the same time, utilize land which in ordinary circumstances would be unsuitable for building purposes.

Street Planting

Not only is it necessary to preserve the hill-tops and valleys and other natural beauties, but as far as possible the amenities of town life. In most communities there is a considerable proportion of the population which enjoys reducing everything to a dull level of ugliness, and seems almost to take a delight in removing everything in the nature of a tree or shrub.

The maintenance of trees and grass is always a troublesome question in England, especially in the neighborhood of our manufacturing centres; but in America, although they have equally busy manufacturing districts, it seems quite easy to dispense with forecourt fences and to throw open stretches of greensward right up to the house itself. Such a town as Rochester, N. Y., or Detroit, Mich., for instance, where thousands of motor cars are manufactured every year, despite the absence of fences there is abundance of grass and trees, and nothing can surpass such towns as Los Angeles and other towns of the West and Middle West in this respect.

The way in which trees are ruthlessly cut down in this country whenever an estate is developed still leaves room for education, and the same process of destruction takes place wherever our countrymen settle. It would be a good thing if a license had to be obtained from the local authority before cutting down any tree of over twenty years' growth, but this is a reform which has yet to come.

Control of Advertising Hoardings, etc.

The control of street advertisements and hoardings comes within the powers given under the Town Planning Act, and here, too, public opinion is coming round to the view that advertisements need not necessarily be ugly.

They very often are, it is true; but this is more often due to want of thought than deliberate intention to offend. Too often the landscape along our railway routes and main roads is stamped for ever in our memories with "Pott's Pink Pills" or "Biles' Bilious Beans," writ large in the foreground. Such monstrosities ought for ever to consign these goods to perdition, but short of this all such advertisements should be subject to annual license by the local authority and a good license fee per square foot.

The establishment of tentative experiments in civic survey work for particular areas has revealed to some extent the mass of preliminary information and statistical data necessary to a full understanding of the problem. In few, if any, cases is it possible for a man to grasp the details of the many-sided issues which beset the problem of town planning, and the civic survey is an attempt to bring together and collate the whole of the available information in a graphic form which will appeal not only to the professional town-planner, but to the members of municipal councils and others who often have not the time to properly study the problems affecting their town.

The heads under which such information is most profitably grouped may be taken as:—

(1) The site: (a) topography; (b) history.

(2) The industries: (c) growth of commerce; (d) causes and direction of growth.

(3) The transit: (e) traffic requirements—origin and directions; (f) water traffic, railway traffic, road traffic.

(4) The enjoyment of life: (g) health requirements, water, sanitation, fire prevention; (h) amenities, architecture, parks, and playgrounds.

And last, but not least:—

(5) Financial considerations: (i) land value and property; (j) rating, taxation, and loans.

It may seem to some that this covers almost as wide a field as the examinations of the Surveyors' Institution. If so, it is a tribute to the skill and forethought of those who have planned the Institution's examinations to embrace the many-sided activities of our many-sided profession.

Conclusion

In matters of town planning, however, we must realize that to foresee and provide for the whole future growth of our towns is not one man's job, but many.

Every profession and every business has a right to be heard, and the plan itself must be the result of whole-hearted co-operation between the surveyor, the engineer, and the architect.

In the town plan an attractive site is of little good without proper means of communication and efficient buildings.

The most perfect of communications by rail, by road, or by water will be unsatisfactory unless the site is wisely chosen, properly surveyed, properly drained, and properly built.

The most attractive design or grouping of buildings will be of no avail unless the site is first of all suitable, the roads are properly graded, and the means of communication the very best that can be obtained.

Co-operation, therefore, between the professions is necessary from the earliest stages of a town-planning scheme, and so far as this Institution is concerned we can rely upon its willingness to do its share in co-operation with the architect and the engineer in the important work of planning the future of our towns."

Smoke Consumers in Sherbrooke

The Sherbrooke, Que., city council has passed a by-law making it compulsory for all manufacturing plants using soft coal to install smoke consumers. As there are some twenty such plants in the city which must comply with this by-law, manufacturers of smoke consumers will do well to cover this field.

The Manufacture of Portland Cement

What Portland Cement is, and a Description of the Different Processes Followed in its Production

THE field of Portland cement has become so broad, with its applications to foundations, fortifications, bridges, breakwaters, docks, canals, reservoirs, dams, buildings, sewers, silos, streets, in fact almost every other field of constructional endeavor, and works of remarkable neatness and durability have been executed, yet there are a great many builders and contractors who, when asked how Portland cement is made, show a hesitancy that denotes ignorance. Mr. A. C. Davis, F.C.S., Assoc. Inst., in a paper before the Institute of Civil Engineers, Ireland, gives a good description of the manufacture of Portland cement. The following is abstracted from his paper:—

What Portland Cement Is

Portland cement is a chemical product obtained by the preliminary mechanical combination of carbonate of lime with silica and alumina, and which after passing through the succeeding stages of manufacture becomes a mixture of silicates and aluminates of lime.

Portland cement can be produced from any raw materials containing constituents capable of yielding, by calcination of silicates and aluminates of lime which form its chief components and the necessary constituents of these raw materials are lime, silica, and alumina. Small additions of iron oxide are desirable for fluxing these materials.

The raw materials, therefore, used for the manufacture are carbonate of lime, usually in the form of chalk or limestone, and silica and alumina, usually in the combined form of shale or clay. The two materials for the necessary combination indispensable for the manufacture of cement are not always found upon the same site.

The suitability of locality depends upon the manner of the occurrence of these requisites, the location of the deposit with respect to the cement-consuming market and the fuel supplies, for since with every ton of cement manufactured there will be used half-a-ton of coal, the location of the factory in regard to cheap fuel supplies is quite an important factor.

If it were at all possible to find a geological formation of uniform composition containing exactly the right amount of naturally mixed chalk and clay, Portland cement could be made from it by the cheap and simple method of merely burning lumps of the material as quarried, and grinding the resultant materials, but since such a material has not been discovered, this method of manufacture is hardly practicable, for a variation of even one per cent. of the proportion of carbonate of lime in the raw materials, to say nothing of the irregular composition of the other ingredients, is sufficient to destroy the reliable quality of the resultant cement.

In manufacturing Portland cement, however, carbonate of lime and clay, or other argiliaceous material, are first efficiently and accurately amalgamated in certain fixed proportions, either with the addition of water to the raw materials, or by the fine grinding and mixing of the same in their dry state.

The composition of a prepared mixture of these raw materials should be roughly three parts of chalk or calcareous constituent to one of clay or argillaceous constituent.

In the United States most of the cement produced is from the Lehigh Valley argillaceous limestone which contains rather more clay than is required for a correct mixture. To this a small amount of pure limestone, usually 10 to 20 per cent., is added, to bring the mixture up to the necessary percentage of calcium carbonate required in the manufacture.

It will thus be seen that, given chalk and clay in approximate proportions of 3 to 1, or lime with silica and alumina in any other form, it is of the first importance that these materials shall be treated with a full knowledge of the all-important chemical and mechanical operations of combining them, which alone can secure the manufacture of a reliable product.

The preliminary mechanical blending of the raw materials for the manufacture of Portland cement is a stage requiring the utmost technical skill, for the thoroughness of the process primarily determines the quality of the resulting cement, and if the manufacturer is to turn out a product of reliable quality, the scientific supervision of this branch of the manufacture is of paramount importance.

The first conditions of any method of preparing raw materials for Portland cement manufacture are, that they shall be (1) correctly proportioned, (2) very finely comminuted, and (3) thoroughly mixed.

The proportions of chalk and clay must be kept to a standard as close as possible to the ascertained analysis, work which, at the present time, in the most successful cement works, is carried out under the supervision of the works chemists.

It is firstly essential that extreme care should be exercised in obtaining the correct proportions of the chalk and clay, or whatever other raw materials may be used in the process, so that the resultant mixture may be relied upon to contain the exact chemical constituents necessary for the manufacture of a thoroughly sound cement; for, if the raw materials are not mixed in this proper proportion, nothing can be done later to correct it, and the result will be an inferior product.

The proportion of the ingredients is governed by continuous laboratory checking of the raw materials as they are quarried, and this testing by the works chemists goes on night and day or as long as the manufacture is proceeding.

Processes of Mixing

There are two principal methods of mixing the raw materials: namely, firstly, by the "Wet Process," applicable mainly, though not solely, to soft materials, the correct quantities of the raw ingredients being ground and mixed by the aid of a considerable amount of water. Secondly, the "Dry Process," in which the perfectly dry materials are ground together to an impalpable powder or "flour," and subsequently mixed to correct chemical proportions.

The wet process of mixing the raw materials is particularly adapted to such materials as are easily disintegrated by the addition of water. By this process the chalk, as quarried, and clay, are weighed into what is called a "washmill," where a large amount of water is added. The wash-mill is a circular brick-lined pit, some 15 feet or more in diameter, and 5 feet deep. In the centre of this pit is a concrete or brick pier carrying a vertical shaft driven through a crown-wheel and pinion. The vertical shaft carries a circular framework, from which are suspended harrows fitted with steel tines. The passage of these tines through the chalk and clay suspended in water tends to break up the lumps and convert the mixture into a liquid of thick creamy consistency, which is kept in the mill until it is fine enough to pass the screens covering the outlet ports. The product of the wash-mill is termed slurry or slip.

In some instances the further reduction of the raw materials is effected in wash-mills alone, while with some harder materials it is necessary for the slurry to be treated finally in the tube-mill.

Slurry from a wash-mill plant contains about 42 per cent. of water, and leaves a residue of less than five per cent. of its solid constituents on a seive of 32,400 meshes per square inch.

The tube-mill, as used for wet grinding, consists of a drum (about 20 feet long and 6 feet diameter) made of steel, and protected against wear and tear by renewable cast-iron plates. The drum is nearly half full of flint stones, and its interior is easy of access through manholes. The raw mixture, previously reduced by the wash-mill, flows through a hollow journal into the grinding drum, which slowly revolves. After being thoroughly ground by the flint stones, the material is discharged through the hollow journal at the opposite end.

In the latest practice the wet process is somewhat modified to allow of harder materials than chalk and clay being treated thereby. This modification is known as the "Thick Slurry" process, and the raw materials are first of all crushed to a size not exceeding a 2-inch cube, then passed into a mill of the ball-mill type—i.e., a revolving drum containing steel balls up to 5 inches in diameter, together with a stream of water. The partially ground slurry issuing from the ball mill is then treated by a tube-mill, where the final reduction occurs.

"Thick slurry" contains about 35 per cent. of water and is usually even more finely ground than wash-mill slurry.

Dry Process

In the dry process method of dealing with the raw materials for cement manufacture, the calcareous and argillaceous materials, of whatever substances they may be composed, have first to be dried after passing the preliminary crushing machinery. The dryers often take the shape of expensively constructed brick-work kilns, but, with the more general adoption of the dry process of manufacture, little time was lost in inventing a less costly and more efficient plant which could also be worked at a much reduced labor cost. The dryers now usually employed, therefore, in the most modern plants, consist of revolving cylinders some 30 or 50 feet in length, and about 4 feet in diameter. These rotary drying drums, as they are termed are supported on steel tyres, resting on heavy friction rolls, and the drums are rotated when in use at a speed approximating two revolutions per minute, and are usually set with an inclination of about one-half inch per foot.

The raw materials after passing the crushing rolls are introduced into the upper end of the dryers, and are immediately caught by cascading channels fitted inside the drums, which lift and drop the crushed raw materials as the drum revolves, and present them to the hot gases passing through the drums in the opposite direction to the way the materials are traveling to the lower or outlet end. The waste heat from the kilns is thus employed for drying purposes; or, again, furnaces are sometimes arranged to rotary dryers for the external heating of the drum.

Dry Grinding and Mixing

The raw materials after being crushed and dried must then be reduced to an extremely fine powder or "flour" by such plant as is adapted for clinker grinding, and then are carefully and thoroughly mixed to the proper chemical proportions before being conveyed to the kilns for burning.

This dry process of manufacture has been employed where the raw materials cannot be satisfactorily reduced by wash-mill plant.

In United States and Canada the dry process is generally adopted.

Preparing Raw Materials

It will be seen, therefore, that in preparing the raw materials for the manufacture of cement, the chalk and clay, or other materials of similar composition must first be reduced to the utmost fineness, either by the addition of water or by dry grinding, either of which processes breaks down the cohesion between the particles, and leaves the material in a very finely divided state, the physical properties of the respective materials to be dealt with generally determining which method of reduction is to be adopted.

Final Composition of Raw Materials

Now, before the prepared raw materials pass to the next stage in the manufacture—that of burning—the composition of the raw material mixture is ascertained by analysis and tests and the carbonate of lime (familiarly known by its chemical formula, $CaCO_3$) should be kept within, at most, one-half per cent. of the quantity found to produce the best cement. This percentage of lime varies slightly in different works, according to the many geological formations contributing to the manufacture, but, roughly, a combination of 75 per cent. of chalk and 25 per cent. of clay will produce a cement of good quality. If any carelessness is permitted in the mixing process, the results are likely to be disappointing, for when the proportion of clay runs too high (or, say, the percentage of lime carbonate falls below 75) a compound is obtained which, in the burning process, will fuse at a temperature lower than that required for the production of sound clinker, thus rendering it comparatively useless. On the other hand, an excess of chalk (above, say, 77 per cent.) will allow a mixture to sustain the highest temperature in the kiln without risk of fusion, but the resultant clinker would be of doubtful quality because of its high-liming or expansive tendencies when ground for cement.

Again, a variation in the amount of carbonate of lime, even to one-half per cent., is found to alter appreciably the tensile strength of a cement—namely, high lime increasing the strength, and low lime producing cement of little strength.

Analysis of Mixed Raw Materials

The chemically mixed raw materials prepared in the ordinary course of manufacture may, therefore, analyse in this way:—

Silica	16.5	Clay.
Alumina and Oxide of Iron	6.5	
Undetermined	..	
Carbonate of Lime	75.5	Chalk.
Carbonate of Magnesia	1.0	

From such a material, if properly treated in the further stages of manufacture, a good commercial cement, testing at least 600 lbs per square inch in seven days, should be produced. The raw materials after combination are then carefully mixed and proved before proceeding with the manufacture.

Burning or Calcining

The next stage in the manufacture of Portland cement, following the scientific and mechanical preparation of the raw material, is that of burning at a high temperature, or calcining, the raw product to the point of slight vitrification, resulting in what is commonly called a cement "clinker."

In the raw materials it will be observed that there is no combination between the carbonate of lime on the one hand, and the silicate of alumina on the other hand; in the conversion of the prepared raw materials into cement clinker by burning, the silica and alumina of the clay immediately enter into combination with the lime, thus forming calcium silicates and aluminates. These compounds are the important constituents of a Portland cement, and give to it, when combined in their proper proportions, its hydraulic properties. None of the cements of commerce, however, are made up wholly of these three ingredients, for the raw materials from which cement is made are never quite pure. It has been found, for instance, that iron oxide behaves, in burning a mixture, the same as alumina, and that a good cement could be made in which all the alumina was replaced by iron oxide, but the essential elements of a good cement are that it shall contain at least the necessary amount of silica and lime.

Heat Regulation

The calcining process is a purely chemical one, and it is a stage of the manufacture involving great responsibility, for, just as in the primary blending of the chalk and clay, a faulty mixing can make or mar the quality of the cement, so can the deficient burning of the material destroy all that is valuable in the finished product. If the heat be not sufficient, the necessary chemical changes do not take place, and a similar unsatisfactory result is obtained.

The proper degree of burning is indicated by the formation of a dense greenish-black clinker when coming from the kilns. Light-burned clinker is yellow and soft, while overburned clinker is fused and slag-like. Thermometric measurements made during the process of calcination show that for normal Portland cement burning, a temperature is required in the kiln amounting to about 1,400° Centigrade, or 2,500° Fahrenheit. The temperature is variable, according to the percentage of carbonate of lime contained in the raw materials—namely, the higher the proportion of lime the higher the temperature which is necessary to produce complete diffusion in combination with silica. Iron oxide also has the effect of reducing the clinkering temperature.

Types of Kilns

The kilns for burning the raw materials are constructed for either an "intermittent" or "continuous" process. The intermittent kilns now generally adopted are those employed in the wet process, and are of such a design that the burning necessitates distinct loading and drawing operations, giving intermittent working, and demanding the complete cessation of the burning process during the drawing operation.

In the continuous kilns, the burning of the raw material proceeds without a break, and the drawing of a clinker takes place at the same time without interruption, thus making a continuous process.

Continuous kilns are generally costly to construct and require skilled labor for their operation. They are economical in fuel, and where they are used the calcining processes are much more regular, and the cement is of better quality.

In the category of continuous kilns we come to the process of burning by the "rotary" kiln, which is the most modern appliance for calcination. The manufacture of cement by the rotary kiln may be said to have revolutionized the industry, and this method of burning the raw materials is, perhaps, the most scientific and practical invention that has been introduced into the manufacture since Portland cement was first known. Although the use of this kiln is a technical and expensive process, involving heavy capital outlay and high cost of production and continual upkeep, there is nothing yet in sight to outclass this invention in the manufacture of Portland cement.

Although the rotary kiln was the subject of much doubt and prejudice when first introduced, it is safe to say that no new cement factory would be erected at the present day without a rotary kiln. The rotary kiln consists of a slightly inclined steel or wrought-iron cylinder, usually from 100 to 200 feet in length, and 6 to 9 feet in diameter, and is inclined to the horizontal at about 1 in 30. The size of the kiln within these limits determines the quantity of the output—a rotary kiln 200 feet long, and 9 feet in diameter, producing some 1,200 tons of clinker a week, with night and day running. The rotary kiln is lined with radial firebricks, some 9 in. in thickness, and the long cylinder is mounted on tyres running on rollers, and is slowly rotated by gearing.

Rotary Process of Burning

The cement-making materials are continuously fed into the kiln through a pipe at the upper end in the form of either liquid mud (slurry) or dry powder, according to the process adopted in preparing and mixing the raw materials. Finely ground coal is almost always used as fuel, and this is introduced into the lower or outlet end by a jet of air issuing from a blast fan.

When the kiln is started the fine coal is ignited, and after a time a white heat is obtained in the lower end of the cylinder. The raw material is then fed into the kiln, and, as it gradually descends into the zone of heat generated by the perfect combustion of the finely ground coal fed into the cylinder from the opposite end it parts with its carbonic acid, forms little balls which reach nearly a white heat in the lower third of the kiln, and finally issues at the lower end as well-burned clinker in grains about the size of a large pea. The greatest heat is naturally near the fuel-jet, or outlet end of the kiln.

The operation of calcining is a continuous one, and with proper care under or over burning may be avoided. The hot clinker is cooled by passing through rotary cooling drums similar in construction to the rotary kiln but much smaller in size.

Cooling Drums

The cooling drums now generally in use in the country are placed at the lower end of the kiln, and receive the hot clinker as it drops finally from the kiln. The coolers generally consist of tubes some 40 feet long and 4 feet in diameter, containing cascading channels for lifting and dropping the hot clinker as the coolers rotate, thus presenting it to the cold air passing through the cooler on its way to the kiln. The coolers rotate at a somewhat higher speed than the furnace tube, and by the air for the latter being drawn through the red-hot clinker a fair proportion of the otherwise lost heat is retained and utilised. When the clinker passes from the coolers it is quite cold enough to handle, and to pass to the further process of grinding into powder.

The first stage in the reduction of the clinker is generally carried out by an ordinary stone-breaker or crusher, or by rolls, which reduce any large lumps to sizes from about ⅜-inch cube down to coarse dust, and after this operation the clinker is conveyed to the fine grinding machinery.

In modern works the preliminary grinding of cement clinker is carried out by the ball-mill, and from this mill the coarsely ground material is conducted to a tube-mill which finishes the fine grinding previous to storing the cement. The ball-mill consists of a cylindrical grinding drum, mounted on a steel shaft running through it, and provided with a tightly-closed sheet-iron casing. The grinding drum is composed of overlapping steel grinding plates, in one-half of which are holes for the ground material to find its way through to the fine sieves externally surrounding the drum, and through which the somewhat coarsely ground cement passes and is conveyed to the tube-mills for finer grinding. The crushing action of the ball-mill is caused by the revolving of the drum, which contains a number of steel balls of various sizes between which the clinker is crushed and pulverized.

For the finishing process—the fine grinding proper—the tube-mill is employed, which grinds by means of the round flint stones or steel pellets contained within it.

The tube-mill consists of a wrought iron revolving cylinder, with hollowed out pivots at both the feed and delivery bearings, and is about one-half full of rounded flint stone, for other grinding medium. The coarsely ground cement is fed from the ball-mill into one end of the tube-mill, and the rotary action of this mill, similarly to the ball-mill, finely pulverizes the cement as it passes through the falling flint stones to the delivery end.

The finished cement is ground sufficiently fine to pass through a 180 x 160 mesh sieve with about 10 per cent. residue, and finer grinding can be readily accomplished by the manufacturer if necessary; but this means a reduced output from the plant.

From the grinding mills the cement is conveyed into the stores, and after it has cooled down the material is ready for loading out at the factory.

New Substation of the Mount Royal Tunnel and Terminal Co., Ltd.

The Mount Royal Tunnel and Terminal Company, Limited, are constructing on a site on Douglas Road and Canora Street, Mount Royal Model City, a terminal sub-station in connection with the Mount Royal tunnel. Power will be purchased and brought into the station, which is just outside the west portal, through cables in duplicate running in ducts through the centre wall of the tunnel from the Dorchester Street terminal.

The building is 92.6 x 76 ft., and 43. ft. in height. It consists of two sections, one being the main machine room and the other consisting of rooms for various auxiliary machines. The machine room is separated from the others by a brick wall running through the centre of the building, communication being by means of two doors. The chief machine room occupies the front portion, and the remaining rooms are at the back, and are divided into three storeys. The motor generator sets will be placed in the main room, which has a floor space of 4,000 feet, and will be equipped with a travelling crane running the entire length of the room, and carried on steel posts, stanchions, and beams. The concrete floor, 12 inches thick, will carry hundreds of iron conduits in which will be placed the various wires.

On the same level as the main room and at the back are the bus bar room, feeder entry room, and the power transformer rooms. Above these are the oil switch room, the lightning arrester room, and the signal and lighting transformer rooms. On the third floor are situated the oil switch control batteries and the upper part of the lightning arrester room. In the basement the oil room, bunkers, etc., are located.

The foundations and floors are of concrete. The exterior is of tapestry brick with trimmings of patent stone made by the company. The windows have steel sashes and rough rolled plate glass. The roof of concrete is carried on steel trusses, with a clear span of 44 feet.

The walls of the machine room are lined with a glazed brick dado to a height of 10 feet from the floor; above this, the walls are lined to their full height with cream pressed brick. The whole of the backing of the internal cross walls is of plastic brick. The transformer and battery rooms are ventilated by means of shafts, while the machinery room has a special system of ventilation, the ventilators measuring six feet across. The interior doors are of iron or steel Kalamine. The company are carrying out the construction work themselves. The Metal Shingle and Siding Company, Limited, Montreal, executed the roofing; Steel and Radiation, Limited, Toronto, supplied the metal sashes and boilers for heating; the James Walker Hardware Company, Montreal, the hardware; and Dartnell, Limited, Montreal, all the brick except the plastic, which was made by the National Brick Company of Laprairie, Limited.

View of the Substation at Mount Royal Model City.

There was a great deal of optimism shown at the annual meeting of the Builders' Exchange, recently held at Saskatoon, Sask., and the general opinion seemed to be that the building outlook for the present year is brighter than it has been for a considerable time. Among the officers appointed for the year were: President, Jas. Priel; Vice Presidents, A. W. Cassidy and A. E. Richardson; Hon. Treas., A. Rutherford; Secretary, M. R. Pout.

Some Comparative Values and Costs of Different Types of Street Pavements and Roads

Considerable has been published on different types of street pavements and roads from the point of view of the method of construction. The following paper by E. M. Le Qua, in "Engineering and Contracting," gives some comparative values of various approved forms of street pavements:—

The life of a pavement is determined by two wholly different factors or a combination of the two—natural durability of the materials of which the pavement is constructed, and the amount of punishment the pavement receives due to wear, tear and age. The destruction due to age is independent of that due to travel. The statement that a certain pavement has lasted a certain number of years means practically nothing as regards its durability unless the quantity of travel, preferably in tons, per square yard, per year is given. To the neglect of this principle is due the conflicting statements about the durability of various kinds. From the point of economy alone, the following factors must be taken into account in comparisons:

(1) First cost.

(2) Interest on first cost.

(3) Payments to sinking fund to redeem debt incurred for construction.

(4) Maintenance cost including cleaning and watering.

(5) Useful life of the pavement.

(6) Value of the worn-out pavement for purposes of renewal.

Maintenance consists of the following separate divisions besides the cost of watering:—

(a) Interest on first cost.

(b) Annual payment to a fund to redeem bonds in (x) years at (x) per cent. interest.

(c) Annual payment to a sinking fund to provide sum necessary for reconstruction at the end of (x) years.

(d) Cost of ordinary repairs during life of pavement per square yard per year.

(e) Cost of cleaning per square yard per year.

(f) Total cost per square yard per year.

This latter comparison is for an annual check and is entirely separate from the one above. Compared on this maintenance basis in the city of Boston:—

	Life.
Granite blocks, cost annually, $0.58 per sq. yd.	13 yrs.
Sheet asphalt, cost annually, $0.57 per sq. yd.	9 yrs.
Macadam, cost annually, $0.78 per sq. yd.	5 yrs.

It was found that pavements are often continued in use long after it would be more economical to renew than to repair.

Although cost is the great item in pavement comparison the public in general demands that many more things be taken into account and the following pavements will be compared on the basis of the essentials of a perfect pavement, namely:—

(1) Cheapness. No matter how good a pavement is unless the money for its purchase is at hand, it is not available. So the question is, what is the best obtainable with the money you have.

(2) Durability. Some materials have only a certain life whether they are subjected to traffic or not, such as asphalt and untreated wood. Where traffic is the governing factor, it, in turn, is influenced by width of street, character of pavement, presence or absence of street cars, and state of repair.

(3) Ease of Cleaning. An economic and sanitary factor.

(4) Resistance to Traffic. Pavements are constructed for the transportation of vehicles and anything hindering this is important.

(5) Non-Slipperiness. The efficiency of a horse depends on his foothold. Infinite strength is of no avail if there is no place to apply it.

(6) Maintenance. Closely allied to first cost and depending on material and traffic. With some pavements, as treated wood and asphalt, a certain amount of traffic is more beneficial than otherwise.

(7) Favorableness to Travel. Ease and comfort of riding and decrease of wear on vehicles.

(8) Acceptability. Lack of noise, reflection of light, radiation of heat, emission of unpleasant odors and other qualities concerning the pedestrian and adjoining residents.

(9) Sanitary Quality. An essential to health in any city.

Sheet Asphalt

This type of pavement is suitable for use, with a proper foundation, for medium to heavy traffic, and in some parts of Canada is used and proposed, with a 6-in. concrete base, for very heavy traffic. It is not suitable on grades steeper than 5 per cent. as a general rule, but has been used on 7 per cent. grades. It wears fairly even, with a tendency towards ruts and holes under heavy traffic. Its advantages are ease of traction, smoothness, comparative noiselessness under traffic, impervious to water, easily cleaned, pleasing to the eye, suitable to practically all classes of traffic, no vibration or concussion given to passing vehicles, and comparative low first cost and maintenance. Its disadvantages are, slipperiness under certain atmospheric conditions, disintegrates if excessively sprinkled or otherwise subjected to constant moisture, although asphaltum is impervious to either fresh of salt water, becomes soft and wavy under traffic in extreme heat, may crack and become friable under extreme cold, and is not adapted to steep grades.

In 1911, 2,348 mi. of asphalt sheet were laid in Brooklyn, Boston, Buffalo, Chicago, New York, Philadelphia, St. Louis, and Washington, D.C. Chicago, Washington, Philadelphia, New York, and Winnipeg, Canada, have more than of any other type. Maintenance costs vary from $.35 per sq. yd. in Brooklyn to $.30 per sq. yd. in London, depending on age and traffic. When properly constructed, asphalt is good for a life of from 16 to 22 years.

Asphaltic Concrete

Suitable in most places where sheet asphalt is used and in some where it is not. Has been used satisfactorily on grades of from 2 per cent. to 7 per cent. with transverse, staggered grooves cut for a foothold on the latter grade. Is slippery in wet weather, with tendency to wear into holes under heavy traffic. Slightly noisier than sheet asphalt, with a life depending mainly on the toughness of the stone aggregate. Cost values are from $1 to $2.50 per square yard, the latter including grading and foundation.

Asphaltic Macadam

Generally proposed where traffic is not quite heavy enough to necessitate sheet asphalt, with the same foundation as the latter. It may take the place of sheet asphalt on grades greater than 5 per cent. In Canada it is often laid on Telford base, consisting of stones 8 in. thick laid on edge.

Costs vary from $.77 in Baltimore to $1.36 in Ontario.

Advantages are freedom from dust, low external and internal wear on road metal, imperviousness and a degree of density of surface, noiselessness, low traction resistance, and is sanitary. Disadvantages are slipperiness at times and variability of penetration and distribution of road metal.

Asphalt Block

This type affords a better foothold than sheet asphalt owing to a coarser stone in the aggregate and on account of the joints between the blocks. An objection is that the blocks have to be all manufactured at one location and transported to the locality where used while a portable sheet asphalt plant permits a smaller haul. This is counteracted in repair, however, where the removable blocks allow an easy reconstruction without necessity of a resurfacer or mixing plant.

Suitable for residence streets of light traffic minus car tracks, with a profitable life of ten years. Cost of construction averages $2.70, with maintenance from $.062 to $.10 per square yard. The pavement is very hard to keep clean when roughened and worn at edges.

Wood Block—Treated

An ideal pavement where traffic is heavy and noise a detriment. Except for its high cost and a tendency toward slipperiness when wet it is suitable for streets with all degrees of traffic. Cost from $2.50 to $3.50, including grading. Maintenance cost from $.014 to $.26. It wears very evenly and has a life of from 10 to 20 years.

Advantages are noiselessness, long life, smooth, easily cleaned, and sanitary. Disadvantages, tendency to slipperiness in wet weather and to bleeding and warping in hot weather due to improper treatment or laying.

Brick

This type is good under all conditions as far as durability is concerned when made of a good quailty product. It is noisy and should not be used where noise is a detriment. With lugs, it can be laid on fairly steep grades. It is not easy to broom, but cleans readily with a flusher. Advantages, durability, slight resistance to traction, dustless, and furnishes good foothold. Disadvantages, large coefficient of expansion, noisy, and tendency to edge wear producing cobbles and holes. Life with heavy traffic and car tracks, 8 years, without tracks, 15 years. Costs $1.85 to $2.95, with a maintenance cost not generally exceeding $.02 per year unless it is treated with a bituminous coat.

Concrete

Its life is not as long as that of brick, but when properly constructed concrete is capable of rendering service fully commensurate with its cost of construction. Costs are quite modified by local conditions, but generally average about $1.85 per square yard. Most of it would admit of resurfacing after 15 years. On several jobs in Illinois five year serial bonds, payable annually, were issued which gave a total cost at the end of a 25-year life, including first cost, interest and maintenance of $3.19 per square yard per year. Concrete is smooth, easy to clean, and gives a good foothold when surfaced, but is dusty, slippery, and noisy without a bituminous coat.

Stone Block

Is very good where the traffic is of the heaviest and most destructive type. When the blocks are so used they should be specially selected and tested. Granite and quartzite are usually used, but the choice of kind should be governed by the availability. With a concrete foundation, well dressed and close jointed blocks of small size, a life of 30 years is not uncommon. The average cost with a grout filler is $3.50 per square yard, with a meintenance of $.001 to $.02 per square yard. The pavement is durable, adapted to grades, and easy to clean when smooth, but is slippery, noisy, rough and unsanitary when worn.

Tar Macadam

This macadam has many advantages over water-bound, is less perishable, has a longer life, is practically noiseless, preserves a smoother surface, and requires less maintenance. The cost is a little more than that of ordinary macadam, but its increased life easily compensates for this, and it will take a considerably heavier traffic. It is not generally used on grades of over 1 in 30. Cost averages $.85 per sq. yd., with comparatively little maintenance. A patent of this type called Tarmac, using broken slag and tar mixed in a machine has been used to a considerable extent in England and has given good satisfaction.

Water Bound Macadam

This is suitable for light traffic in residence districts when treated with a bitumen or light oil, but without treatment soon ravels and becomes very dusty. Yearly maintenance is practically necessary at a cost of from $.04 to $.12, depending on the treatment. First cost depending on locality, varies from $.50 to $1 per square yard. Below are given the opinions of a group of prominent Canadian engineers as to:

1.—Place for Pavements in Order of Popularity

(1) Light residence to semi-business: sheet asphalt, bitulithic, asphaltic concrete, wood block, asphalt block, concrete.

(2) Semi-business to medium heavy traffic: bitulithic, sheet asphalt, asphaltic concrete, wood block, asphalt block, concrete.

(3) Heavy traffic: brick, wood block, stone, scoria block.

(4) Along street railway tracks: wood block, brick.

(5) For quiet streets: wood block, bitulithic, sheet asphalt, concrete.

(6) For graded streets: brick.

2.—Nature of Deterioration

Asphalt Block: edge wear, forming holes and cobbles, noisy and hard to keep clean when worn, disintegrates at bottom.

Asphaltic Concrete: wears into holes, susceptible to marking in hot weather.

Bitulithic: wears evenly, tendency to holes under heavy traffic.

Brick: edge wear and cobbling under heavy traffic, increased noise and unsanitariness as wear increases, slows down traffic when badly worn.

Sheet Asphalt: wears slowly into large holes or patches, heavy traffic causes ruts, cracks hasten deterioration.

Wood Block: rots if untreated, when treated wear is slow and even.

Stone and Scoria Block: wears gradually into holes and cobbles, unsanitary when rough.

Concrete: wears slowly and evenly if well made, otherwise cracks and chips.

Below are given various tabulations of camparison, compiled from data available:—

I.—USUAL LIFE OF PAVEMENTS.—J. B. HITTEL, CHIEF ENGINEER, CHICAGO.

Asphalt	12 to 15 years
Brick	12 to 15 years
Wood block	15 to 18 years
Granite	30 to 40 years

II.—MOST ECONOMICAL PAVEMENT UNDER CONDITIONS.

(a) Large volume of heavy traffic.

(b) Secondary business streets with moderate volume and weight of traffic.

(c) Main city or suburban streets having large volume of light traffic.

(d) Suburban or residence streets where traffic is local and light.

For (a) macadam is most expensive, sheet asphalt slightly better than granite, but granite is preferable owing to the inconvenience of repairs to asphalt.

For (b) macadam is the most expensive, sheet asphalt the most economical.

For (c) granite is most expensive and a material difference exists in favor of sheet asphalt over macadam, though the relative costs do not differ widely.

For (d) granite is very expensive, macadam the cheapest.

III.—FRACTIONAL RESISTANCE.

Asphalt	1 (least)
Macadam	2-5
Macadam (wet)	7-8

IV.—COSTS FOR PERIOD OF YEARS, ASSUMING GRANITE HAS A 25-YEAR LIFE, WOOD 20 YEARS, BRICK 15 YEARS, ASPHALT 18 YEARS.

Material.	First cost per sq. yd.	Exp. per yr. per yd., 1st period.	Aver exp. per yr. per yd., 50 yrs.
Granite	$3.50	$0.294	$0.270
Asphalt	2.00	.208	.164
Wood	3.50	.308	.274
Brick	2.50	.224	.199

V.—DURABILITY.

Material.	Small repairs. Years.	Extensive. repairs. Years.	Complete reconstruction. Years.
Asphalt black	5-10	10-12	12-15
Asphalt concrete	4- 6	6- 8	8-10
Bithulitic	5- 8	10-15	15-20
Brick	8-10	10-15	15-18
Concrete	5- 8	10-12	15-18
Stone—Scoria	10-15	15-20	20-30
Sheet asphalt	4- 8	10-15	15-18
Untreated wood	3- 5	6-10	10-12
Treated wood	8-10	12-15	15-18

VI.—GENERAL QUALITIES BY THE PER CENT SYSTEM.

Quality.	%.	Granite.	Wood.	Asphalt.	Brick.
Cheapness	14	8	8	11	11
Durability	21	21	16	15	16
Ease of cleaning	15	10	14	14	15
Light traffic resistance	15	13	14	12	15
Non-slipperiness	7	7	4	5	6
Ease of maintenance	10	10	8	6	6
Favorableness to travel	5	2	5	4	3
Sanitary qualities	13	9	13	12	10
Totals	100	80	82	70	82
Cheapness eliminated	..	72	74	68	71

VIII—GENERAL QUALITIES USING OTHER FACTORS.

	Per cent.	Granite.	Sand stone.	Sheet asphalt.	Block asphalt.	Brick	Macadam	Wood.
First cost	14	4	4	6.5	6.5	7	14	4.5
Durability	20	20	17.5	10	14	12.5	6	14
Ease of maintenance	10	9.5	10	7.5	8	8.5	4.5	9.5
Ease of cleaning	14	10	11	11	14	12.5	6	14
Low traction resistance	14	8.5	9.5	14	13.5	12.5	8	14
Non-slipperiness	7	5.5	7	3.5	4.5	5.5	6.5	4
[1]Favorableness to travel	4	2.5	3.5	4	3.5	3	3	3.5
[2]Acceptability	4	2	2.5	3.5	3.5	2.5	2.5	4
Sanitary quality	13	9	8.5	13	12	10.5	4.5	12.5
Total	100	71	73.5	76	79.5	74.5	55	80

[1]Refers to smoothness and freedom from dust and mud.

[2]To noise, reflection of light and heat, emission of unpleasant odors and other things concerning pedestrians and adjoining residents.

In conclusion would say that many more years must pass and accurate data be kept before a reliable comparison of pavement can be procured. In any pavement construction, great attention must be given to the supply of materials at hand. Also, since prices are generally going upward, it must be taken into consideration that the increasing cost of construction and maintenance is not due alone to an increase in the amount of traffic, but to a necessary increase in cost of materials in years to come.

New Report on Waterworks of Canada

A new edition of "Waterworks and Sewerage Systems of Canada," by Leo G. Denis, has just been issued by the Commission of Conservation. In the present report the various physical and financial data respecting waterworks have been brought up to date and a new section on sewerage systems has been added. The book is a royal octavo volume, handsomely bound in cloth, contains 176 pages of text and is well illustrated with 25 half-tones and 5 diagrams.

In the year of Confederation there were only 7 waterworks plants in Canada; to-day there are 528. These have been built at a total cost of $123,725,633, and entail an annual maintenance charge of $4,558,539. The total daily consumption is 426,877,000 Imperial gallons, which gives an average daily consumption per capita of 111 gallons, ranging from 50 gallons in Manitoba to 143 in New Brunswick.

There are 206 plants supplied from springs or wells and 322 from lakes or streams. In 72 plants the water is filtered and in 21 plants it is treated with hypochlorite. The municipally-owned plants number 396. As to rates, where specified, it is shown that flat rates are used in 209 cases, meters in 30, and both flat and meter in 141.

There are 279 sewerage systems in Canada, having an aggregate mileage of 4,223, and which have been built at a total cost of $74,504,418. In only 75 municipalities is the sewage treated. Proportionally to population, the West, with 28 treatment plants, makes a much better showing than the East, with 47. The total cost of the treatment plants is $3,218,935.

Harbor Development in New Brunswick

Tenders are being asked by the New Brunswick Public Works Department for crib-work and back filling on Pier 16, West St. John, the intention being to have this pier ready for next winter's port business. During the season just ended there was an occasional shortage of pier accommodation. With another pier built, this shortage will be to some extent removed. A temporary wooden warehouse will be erected on this pier. Three dredges are now operating at East St. John, preparing new terminals for the Canadian Government Railways.

Development work has been begun on the tungsten mines near Burnt Hill, Northumberland County, N. B. There is a great demand for this valuable ore.

The federal government has decided to erect a million bushel grain elevator at St. John, N. B., in connection with the Canadian Government Railway system. It is expected that the first unit of 500,000 bushels will be ready for use the coming winter season.

The contract for the construction of the St. John Valley Railway from Gagetown to Westfield has been awarded to the Nova Scotia Construction Company of Sydney, N. S. The contract provides that the road shall be completed in safe condition for operation by February 1st, 1917, and the work fully performed August 1, 1917. This section of railway is to be employed in bringing Transcontinental Railway freight to St. John, the C. P. R. track being used temporarily between Westfield and the city. Until the East St. John terminals are completed, export freight will be shipped from West St. John.

Concrete in Tree Surgery

IN the science of medication of members of the vegetable kingdom, quite an important part is played by concrete. This material has in the practice of surgery a well defined purpose and a certain fixed method of application. Cement in trees fulfils the threefold purpose of stopping decay, serving as a structural support, and providing a surface over which the bark may heal.

The real life of a tree is represented by the bark, a cambium layer just behind it, two, three or four inches of sapwood behind the cambium layer, and the leaves and roots. The inside of a tree is practically dormant. The sap ascends in the outer woody fibre, enters the leaves, undergoes its chemical change which produces the tree food, and descends just inside the bark, building as it goes. The central tissues serve no purpose save physical support.

Decay in a tree attacks and disintegrates the dormant fibre first. The life of a tree affected with decay may be prolonged for some time by removing the decaying material and replacing it with cement. After removing the decay, any remaining fungi—which are the direct cause of decomposition—may be killed by a coat of corrosive sublimate. The cavity is then waterproofed with a penetrating and adhesive waterproofing material and the concrete applied.

Cement improperly put in a tree is worse than none. Sometimes it is necessary to put the cement in in sections, leaving joints to permit of the tree swaying without damaging the joint. The exclusion of foreign substances, especially water, is the all-important task of the tree surgeon. Some sort of waterproofing is applied around the edges of the cavity, which will exclude moisture and still allow the bark to grow over and cover the wound.

Nature responds wonderfully to proper treatment. Save the trees—they provide to the human family comfort, beauty, and pleasure, they hold in check the water that forms our rivers, thereby insuring a more uniform flow, besides contributing in other manifold ways to the well-being of man.

Crusher Parts Wanted

A contractor in the Maritime Provinces wants to get in touch with any Canadian firm carrying in stock parts for the Broadbent Rock Crusher. The name can be obtained from the publishers of this journal.

In the opinion of Mr. Paul Mercier, chief engineer of the city of Montreal, paving of streets can be done more economically by day labor than by contract. This opinion was based on a comparison of prices on work done last summer. Mr. Mercier, however, made an exception in the case of the construction of asphalt sidewalks.

Protecting the Owner and Architect

Toronto, Ont., May 11, 1916.

Editor Contract Record:

I noticed a most interesting article in The Contract Record of April 19th, written by Mr. G. Alexander Wright, entitled, "Bids, Bidders, and Bidding," and which asks for suggestions from the readers of The Record which will correct certain evils that have crept in in this connection.

As I feel that a word from the standpoint of the Bonding Company might be apropos, I take this opportunity of replying to the invitation extended by Mr. Wright.

Summing up Mr. Wright's article, as I see it, a responsible contractor, and by responsible contractor I mean a contractor who is competent and capable of handling any contract he tenders for, "inasmuch as his figures will be carefully compiled and allowances made for a fair profit on the contract," hesitates to bid because he is competing with irresponsible contractors who are inexperienced and who therefore do not figure as carefully or as conscientiously, their main idea being to secure the contract with the hope that they may be able to complete the contract profitably. To be explicit: they have everything to gain and nothing to lose for the price they submit.

The question therefore resolves itself into how can the owner and architect protect themselves against the tendering of irrsponsible contractors without experience and without sufficient financial standing to back up their tender.

The answer is simple. You have at your disposal a quick remedy, by inserting in your specifications the following clause:—

> "The Contractor shall furnish with his tender the consent in writing of a guaranty company authorized to do business in Canada, to issue a contract bond on his behalf, guaranteeing the faithful performance of the contract in an amount equal to 20 per cent. of the amount of the contract, and contractors proposing to tender will make immediate arrangements with their guaranty company for such bond, as the companies require sufficient time to complete inquiries."

This will compel every contractor tendering on the work, obtaining a bond from some guaranty company, who is prepared to back up his tender by their financial resources, guaranteeing that if the contract is awarded to him he will sign the contract and that he will carry out the contract according to the terms and conditions, plans, specifications of the contract. If this plan is adopted you eliminate the inexperienced, irresponsible contractor, without any financial backing, from tendering on the work and get down to the only class of contractor which the owner and architect want to deal with. There are a sufficient number of responsible contractors to still leave the question of price on a competitive basis and this arrangement places no hardship on any contractor who can do the work. He simply arranges with his bonding company for a bond the same way he would arrange with his banker for a line of credit. It relieves the architect and owner of the work of ascertaining whether they are letting the contract to a financially responsible contractor or not, and also whether he is competent in the line of work on which he is tendering, and it does not legislate against the smaller contractor because any contractor, be he big or little, who is responsible and bears a good reputation, can secure credit from a guaranty company up to the amount which they consider he has had the experience and financial responsibility that they can safely back him up for.

In conclusion, let me add that the first protection to the owner and architect is the manner in which the guaranty company carefully considers every contractor's application. Every application is dealt with separately and entirely on its own merits. The moral, as well as the financial standing of the contractor, is taken into consideration along with his ability in the line of work to be undertaken, and it is only after every point is carefully considered that the bond is either accepted or refused.

I wish to thank you for the opportunity afforded me of putting these suggestion to you and hope that they will be considered worthy of publication and trust that you will consider that this article is written entirely from an educational standpoint.

Yours very truly,

Sidney W. Band,
Assistant Manager.
United States Fidelity and Guaranty Co.

Mainly Constructional

East and West—From Coast to Coast

Messrs. Henderson & Taylor were recently appointed municipal engineers at Matsque, B.C.

A brick plant at Cardwell Junction, Ont., which has been closed for some time, will resume operations shortly.

The Maisonneuve Quarry Company has been incorporated with a capital of $45,000, headquarters at Montreal, P.Q.

The Canadian Construction Company, Limited, has been incorporated with a capital of $90,000, headquarters to be in Montreal, P. Q.

The Vulcan Asphalt & Supply Company, Limited, have been incorporated with a capital of $10,000, headquarters at Winnipeg, Man.

The Sanitary Heating and Ventilating Company, Limited, have been incorporated with a capital stock of $50,000. Their headquarters are to be at Ottawa, Ont.

P. Lyall & Sons, Construction Co., Montreal, have received a contract for the reconstruction of the Parliament buildings at Ottawa at approximately $6,000,000.

The Arnot Construction Company, Limited, has been incorporated with a capital of $40,000. The head office of the company will be in Toronto, Ont., and its provisional directors will be David Arnot, Oliver Rouse and John Billington Nicholson.

Amongst buildings for which permits were issued recently in the city of Quebec are two novitiates, one for the Christian Brothers of the Commercial Academy, amounting to $237,000, and the other for the Fathers of the Sacred Heart, to cost $68,000.

A large factory for the manufacture of oxygen and liquified acetylene is to be erected in Winnipeg by a prominent Montreal firm of chemists, on property situated between Wellington and Sargent Avenues, and extending through from Spruce to Pine Streets.

A handsome addition to the public buildings of Sydney, N. S., is a new hospital which is now practically completed. It is a beautifully designed structure built of the best quality pressed brick and is designed and finished throughout on the most modern lines of hospital architecture and construction.

Letters patent of incorporation have been granted to Messrs. Luther B. Smith, of St. John, N. B., E. Lorne Merrithew, of Fredericton, and J. Everett Fenwick, of Millstream, as Smith-Merrithew, Limited, to carry on general contracting business, with a capital stock of $49,000. The head office is at St. John.

The formal opening of the Public Utilities Commission's new offices at Dundas, Ont., took place recently. The building, which was erected by the Dickson Building Company, is of red brick, and is very handsome and well fitted. It is the first chimneyless office building in Ontario, being entirely lighted and heated by electricity.

Work on the Quebec bridge has been progressing rapidly this spring and already two panels have been added to the cantilever arm on the south side. The setting of steel for the suspended span being erected at Sillery has just been started, and according to the superintendent of the bridge, Mr. W. D. Fortune, everything will be in readiness to place the middle span in position by the first week in October, which will virtually complete the structure, making it one of the longest spanned bridges in the world.

A resolution favoring the extension of the Toronto-Hamilton Highway on the Lake Shore Road to a width of 86 feet, and the expropriation of extra land required to widen the roadway was recently passed by the council of Mimico, Ont. This, with similar resolutions from Port Credit and New Toronto councils, will terminate the uncertainty and delay regarding the construction of the highway.

Steel shipbuilding on a large scale has been started in Nova Scotia by the Nova Scotia Steel Company, which is commencing operations at New Glasgow near the plant of the Eastern Car Company. Steamers are to be built for the steel company itself at first, in order to supply the need for additional ocean tonnage. It is probable that shipbuilding in time will prove an extensive part of the company's activities.

Messrs. Quinlan & Robertson, contractors, presented a claim last February to the Orillia Water, Light and Power Commission for upwards of $30,000 in connection with the construction of Ragged Rapids dam, claiming that unexpected conditions at the bottom of the river had occasioned this extra expenditure. The matter has been settled, however, without litigation, on the payment of $7,500 by the Commission to the contractors.

At a meeting of the directors of the Trusts and Guarantee Company, Limited, held recently, it was decided to proceed at once with the erection of a new $500,000 office building on Bay Street, Toronto. Tenders have already been received and contracts will be let immediately. Messrs. Curry and Sparling, architects, have designed the building, and it will be a most distinctive and attractive structure. It is to be eight storeys in height, including basement, with provision for addition of five more storeys at a later date. The front is to be of grey Indiana limestone, with a Stanstead granite base. The main floor will be handsomely finished in French Tavernelle marble. The building will be absolutely fireproof and will contain all the latest improvements in equipment, including the newest type of ventilating system. In size it is 50 x 95 feet. It is expected to be ready for occupation by January 1, 1917.

Obituary

Elmer Lawrence Corthell, D.Sc., President of the Am. Soc. C. E., consulting engineer, bridge and railway builder, river and harbor expert, and a member of numerous scientific societies, died recently at Albany, N. Y.

Lieut. C. S. D. Ross, of Calgary, was recently shown on the casualty lists as killed in action. Lieut. Ross came to Canada from Cheshire, England, and was for some time engaged as civil engineer with the C. P. R., being well known along the line. He left with a Calgary engineer battalion early in the war, and had been in the trenches for over a year.

Lieut. Trafford Jones, who practised as a civil engineer in and about Toronto for some eight years and enlisted last May with the Canadian Army Service Corps, met his death near Ypres during an aerial battle with German aviators when he was shot through the head. He was 29 years of age, and leaves a wife and child, both of whom are in England at present.

Trade Publications

Fire Hose and Accessories—Catalogues F. 2 and J. 1, by the Dunlop Tire & Rubber Goods Co., describing Dunlop fire hose and accessories—the latter for every class of building. Both of these catalogues are splendidly illustrated. The same firm are also distributing an interesting and valuable catalogue on Dunlop mats and matting, inlaid and plain rubber flooring.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks, Sewerage and Roadways

Bassano, Alta.
Tenders are now being received on the supply of about 1,000 feet of vitrified sewer pipe and 1,000 feet of cast iron or steel pipe and specials. Town Engineer, G. W. Murgatroyd.

Dundas, Ont.
The Town Council will shortly call for tenders on the construction of about 5,000 feet of sidewalks. Estimated cost, $5,500. Clerk, J. S. Fry.

Edmonton, Alta.
The City Council propose to expend $12,000 on the construction of plank sidewalks throughout the city. Engineer, S. Haddow.

Hamilton, Ont.
Tenders will be received until June 17th for the construction of a drainage system for the City Council. Estimated cost, $35,000. Engineer, A. F. Macallum.

Morrisburg, Ont.
The Village Clerk, F. R. Chalmers, will receive tenders until 6 p.m., June 5th, on the construction of about 14,600 square feet of granolithic sidewalk.

Simcoe, Ont.
The Town Council are having plans prepared for the construction of about 3,000 feet of earthenware sewers and laterals. Engineer, Guy Marston, Norfolk Street.

St. Hyacinthe, Que.
Tenders on the construction of gravity filters for the City Council will be received until June 28th. Plans and specifications at office of the Clerk, A. Messier. Approximate cost, $75,000.

St. Pierre de Lac, Que.
The Municipal Council are considering the construction of waterworks, at an approximate cost of $10,000. British Columbia stave pipe may be used. Secretary, J. H. Langlais, Val Brilliant.

The Pas, Man.
Tenders will be received by the Town Secretary for the following work:—(1) supply and delivery of two sewage lift pumps; (2) construction of sewage lift chamber. Plans and specifications at office of the Consulting Engineers, Murphy & Underwood, Saskatoon, with the Resident Engineer, The Pas, and at office of the Contract Record, 347 Adelaide Street W., Toronto.

Tilbury North, Ont.
The Township Council are considering the construction and improvement of a number of tile drains.

CONTRACTS AWARDED

Markham, Ont.
The general contract for the construction of 35,000 square feet of concrete sidewalk has been let to John Hare.

Sombra Township, Ont.
The Township Council have let the contract for construction of the Murphy Drain to H. Dickson, at $1,800, and the Arnold Drain to George Hunter, at $2,050.

Toronto, Ont.
The Board of Control have awarded contracts for the construction of sewers to Murphy & Barnes, 23 Temple Avenue, at $6,889, and to the Commissioner of Works, $3,265.

Railroads, Bridges and Wharves

New Brunswick Province
The Provincial Department of Public Works, Fredericton, will receive tenders until June 7th for the construction of a steel truss bridge over the Aroostook River Mouth. The time for receiving tenders on three other bridges has also been extended to the same date.

Ottawa, Ont.
The Ottawa Electric Railway Propose to construct a bridge at Rockliffe Park, estimated to cost $6,000. Concrete and steel construction.

Toronto, Ont.
Bowman & Connor, Engineers, 31 Queen Street W., will receive tenders until June 2nd on the construction of ten bridges for the County of Wellington and one bridge for the Township of Maryboro.

CONTRACTS AWARDED

Fredericton, N. B.
The contract for building the uncompleted portions of the St. John-Quebec Railway has been let to the Nova Scotia Construction Company, 159 Upper Water Street, Halifax, N.S. Approximate cost, $1,750,000.

Public Buildings, Churches and Schools

Tenders and For Sale Department

Tenders for Light Fixtures

Tenders for light fixtures for the new Registry Office will be received by registered post only, addressed to the undersigned, up to noon on **Tuesday, June 6th, 1916.** Plans and specifications may be seen and forms of tender, and all information obtained at the office of the City Architect, City Hall, Toronto. Envelopes containing tenders must be plainly marked on the outside as to contents. The usual conditions relating to tendering, as prescribed by the City By-laws, must be strictly complied with or tenders may not be entertained. Tenderers shall submit with their tender the names of two personal sureties, or the bond of a Guarantee Company approved by the City Treasurer. The lowest or any tender not necessarily accepted.

T. L. CHURCH, Mayor,
Chairman of Board of Control.

22-22

Department of Railways and Canals, Canada

Hudson Bay Railway Terminals

PORT NELSON, MAN.

Sealed tenders endorsed Tender for "Provisions" or tender for "Hardware Supplies," as the case may be, will be received by the undersigned up to 12 o'clock noon, on **Tuesday, the 6th of June, 1916**, for the furnishing of "Provisions," and on **Saturday, the 10th of June, 1916**, for the furnishing of "Hardware Supplies," to be delivered in such quantities at Halifax, N.S., and at such times as may be directed.

Dealers may tender for the total quantities required, or for such portions thereof, as may suit their convenience.

Specifications of requirements, and full information can be obtained from the Purchasing Agent of the Department of Railways and Canals, Ottawa, on and after this date.

An accepted bank cheque in the case of "Provisions" for $500, and in the case of "Hardware Supplies" for $500, made payable to the order of the Minister of Railways and Canals, must accompany each tender, which sums will be forfeited if the party tendering declines entering into contract for supplying any of the goods awarded to him, or in any way fails to properly fulfill the same.

The cheque thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque of the successful tenderer will be held as security, or part security, for the due fulfilment of the contract to be entered into.

The lowest or any tender not necessarily accepted.

By order,

J. W. PUGSLEY,
Secretary.

Department of Railways and Canals.
Ottawa, May 22, 1916.

Newspapers inserting this advertisement without authority from the Department will not be paid for it.—84408. 22-22

Orillia, Ont.

The by-law to provide for the transfer of the power plant to the Ontario Hydro Electric Commission has been defeated. The Town will now proceed with the plant at Swift Rapids, estimated to cost $90,000. Switchboards, water wheel, transformers and other equipment will be required for two units of 1,600 h.p. each. Engineer, W. K. Greenwood.

South Melfort, Sask.

Tenders on the construction of the proposed system of the South Melfort Rural Telephone Company will be received until June 14th by the Secretary, Walter Armstrong, South Melfort Post Office.

CONTRACTS AWARDED

Copper Mountain, B. C.

The British Columbia Copper Company, Copper Mountain, have awarded the contract for the construction of a transmission line from East Princeton to J. MacDonald, Princeton.

London, Ont.

The Hydro Commission have let the contract for the supply of Wire cables to the Northern Electric Company, 131 Simcoe Street, Toronto, and for supply of poles to W. McFadden, Heaslip, Ont.

Fires

Hamilton, Ont.

Residence owned by W. J. Southam. Loss, $10,000.

Montreal, Que.

Store of Louis Wisintainer & Son Company, 58 St. Lawrence Boulevard. Loss, $15,000. Will be rebuilt.

Store building, owned by N. G. Valiquette Ltd., 477 St. Catherine Street E. Loss, $4,000. Repairs will be made.

Wainwright, Alta.

Pump house owned by the Grand Trunk Pacific Railway, Winnipeg. Owners will rebuild.

Westboro, Ont.

Store owned by Frank O'Malley, Victoria Avenue. Loss, $6,000. Owner may rebuild.

Store owned by Patrick Mears, William Street. Loss, $4,500. Will be rebuilt.

Miscellaneous

Montreal, Que.

The Dominion Bridge Company, Lachine, have been asked by the City Council to prepare plans and specifications for headgates for the Lachine Canal. Estimated cost, $100,000.

Preston, Ont.

The Town Council will shortly submit a by-law to authorize the expenditure of $10,000 on a fire engine. All communications must be sent to Mayor Hurlbut, Hurlbut Shoe Factory, Pdeston.

Toronto, Ont.

W. J. McCormick, 2,000 Bloor Street West, is constructing a concrete swimming tank, estimated to cost $3,500.

Trail, B.C.

The Trail Poultry Association have appointed a Committee to consider the construction of a swimming pool and gymnasium, at an approximate cost of $8,000. Secretary, J. A. Wadsworth.

Cut Vent Holes and Fill Settles to Firm Foundation

At various points tbe Coleman-du Pont concrete road, in Delaware, was constructed over swamps. Ordinarily these were drained before the fill was deposited, but in one case the cost would have been prohibitive so the fill was made directly on the surface of the swamp, which floated on several feet of black muck. Below this was a solid foundation of sand and bog ore. It was thought that the weight of the embankment would carry it down to this stratum, but it did not. The difficulty was surmounted by cutting holes through the swamp surface near the toe of the fill. The muck was forced up through these and the solid earth settled down to the firm foundation.

Mechanical Filtration of Water

THE rapid development in the science of bacteriology and the resultant study of water-borne diseases, have in the last few years focused public attention on polluted water supplies and created a demand for pure water. The question of the best methods to employ for the filtration and purification of water cannot be settled by mere dogmatic assertions. It is no more true that any one treatment is the best to employ for dealing with all classes and conditions of water than it is to say that any one type of sewage disposal is applicable to any and every case.

Open sand filters or slow sand filters for purifying water have been in operation for nearly a century, while mechanical filtration or rapid sand filtration first made its appearance about thirty years ago. The arrangement of the filtering material differs little in sections between the rapid and slow processes, but the water under treatment in the mechanical filter is passed through the materials at a speed from twenty to sixty times greater than that which has been found in practice to represent a safe limit of speed in slow sand filtration in order to obtain complete purification of the water.

* * *

The slow sand filtration involves large areas of artificial sand beds which are quite expensive in construction and are sometimes beyond the means of many small communities. There is no doubt whatever, however, that from its inception slow sand filtration has given remarkably good results in purifying polluted water. However, as the efficiency of the slow sand process increases its ability to allow for the passage of water through it decreases. Good results have also been obtained from the mechanical filter, but it is necessary in this process to employ coagulants and generally, though not always, to have pumping machinery to operate the apparatus. The efficiency of the open sand filtration is believed to be exceeded by no other process for removing bacteria and other organic matter, although mechanical filters with a coagulant have given an efficiency only one or two per cent. less. But the possibility of serious lapses in full efficiency is greater with the mechanical than with the open filter.

The general practice in America has been to employ the mechanical or rapid process because of the facility with which clarification can be obtained and the comparative expense and difficulty with which the same result can be obtained by the slow process. Then, too, it has been discovered that mechanical filtration, in addition to being cheaper in first cost and operating cost than slow sand filtration, is better adapted to a wide range of conditions, and with water containing a large amount of fine suspended matter, could be used with success where the slow sand filter would be doomed to complete failure.

* * *

The mechanical system essentially consists of tanks containing sand through which water is passed at a high rate of filtration after it has been treated with a coagulating chemical. This chemical is added to the raw water before reaching the filter and forms immediately an artificial, gelatinous film over the surface of the sand, thereby collecting most of the foreign material on the surface and preventing clogging of the filter. These filters are cleaned at frequent intervals by reversing the current of water through them and washing the suspended matter out through a waste way near the top. While the experimental work of trained specialists in the last decade has placed the mechanical method of filtration on a sound basis, yet its success must be attributed to a greater extent to the development in the design of these filters and to the scientific methods of operation. Elsewhere in this issue is a paper by Thomas Fleming, Jr., on "The Improvement in the Art of Mechanical Filtration," which enumerates in a very detailed manner the developments which have been made. Previous to 1900, mechanical filters were built of wood or steel; modern practice, however, is to build them almost entirely of concrete and equip them as far as possible with automatic control devices for the operation of their different functions. The mechanical filter is almost universal in Canada and the United States; to-day there are approximately twenty million people supplied with filtered water, and of this amount, practically fourteen million, or two-thirds, are supplied with filtered water from some 600 mechanical filtration plants.

Prepare for Mosquito Extermination

THE season is upon us when the extermination of mosquitoes is one of our ever-present problems. Canadian municipalities, however, do not appear to have made much effort to exterminate these pests. In later years their invasion of our larger cities, which formerly were more or less immune, indicates an increase in both number and activity and it is increasingly evident that in defense of the good health of our citizens, to say nothing of our personal comfort, some systematic move must soon be made by our civic authorities to prevent the further increase of these troublesome insects and, if possible, remove the cause of their being.

The city of Philadelphia is an example of what some of the larger cities on this continent have been attempting during the past few years. Since 1912 some 65 miles of ditches have been reconstructed with the idea of improving the drainage; approximately 12,000,000 square feet of pools have been oiled or sprayed; 27,000 sewer inlets oil treated and 300,000 square yards of weeds cut down. The following details of this work are taken from the advance report of the New York State Conference of mayors and other city officials prepared by Mr. W. H. Connell.

Experience in Mosquito Extermination

The mosquito extermination campaign in Philadelphia started in July, 1912, with an appropriation of $5,000 for experimental and actual work. The poor drainage system over 8,000 acres of lowland in the southern section of the city caused through obstructed ditches, which had not been properly maintained for several years previous to that time, had practically converted this area into swamp land where millions of mosquitoes bred annually. During the past year 30 different varieties of mosquitoes were identified and large numbers of malaria-bearing mosquitoes were found in all sections of the city.

Preparatory to starting the actual work of mosquito extermination in 1913 the early part of the year was devoted to an educational campaign in which many lectures were given and over 100,000 pamphlets bearing on the life history of mosquitoes and practical methods of extermination were distributed throughout the city to solicit the interest of the public. The appropriation of $5,000, however, did not permit of a decisive fight against the insects in the city limits simultaneously, and the work was confined principally to sections where they bred habitually and to relieve local complaints. During this year the salt-marsh species, a larger and more active mosquito than the house-breeding variety, made its appearance in the lower part of the city in large numbers and much time and attention were given to extermination work against this particular pest in its original breeding places.

The force of men varied from two to eight during the season of 1914, and, while the appropriation was curtailed, a great deal of very satisfactory work was accomplished in oiling pools throughout the summer and latterly in oiling sewer inlets, which was tried out for the first time in the fall and continued until the middle of December. As a result, mosquitoes which ordinarily hibernate in sewer inlets over the winter were practically prevented from breeding and no complaints of the mosquito nuisance were received until four weeks after the first heavy rains in May, 1914.

The work of mosquito extermination in 1915 began on June 1, with an appropriation of $2,500, and extended to November 15. Probably no season since 1912 proved so very favorable for breeding purposes, as rain occurred at short intervals and formed thousands of pools. Breeding places on roofs and in tin cans on dumps and private property added to the multitude of complaints of mosquito annoyances. At one period of the summer the situation became so bad in many built-up sections of the city, bordering on large unimproved areas where weeds were permitted to grow to a height of 6 or 7 feet, that the city was forced to put an additional force of 200 men at work cutting down areas of weeds infested by mosquitoes. Table I. gives data on the work in 1915.

The actual appropriations for mosquito extermination during the past four years amounts to $13,900, and this amount, of course, is not sufficient to handle such a proposition, so important to the health and comfort of a community of the size of this city. With the limited appropriations, however, much progress has been made, and since 1912 over 65 miles of ditches have been reconstructed, which will permit of the proper drainage of an immense area which has heretofore afforded ideal breeding places for these pests. Approximately 12,000,000 square feet of pools have been oiled and sprayed, 27,000 sewer inlets oil treated and 300,000 square yards of weeds cut down in the effort to improve living conditions during the mosquito season. With a proper amount of money an entirely different plan than heretofore used for mosquito work could be put into effect, which it is confidently predicted would free the city from the mosquito nuisance.

Table I.—Work Done by Philadelphia City Forces on Mosquito Extermination, 1915

	No. of Jobs	Cost of Labor	Cost of Material	Total Cost
Oiling pools	2,600	$ 280.00	$ 49.50	$ 329.50
Oiling sewer inlets .	22,500	1,725.00	142.00	1,867.00
Filling in depressions, ditches, etc.	250	1,145.00	150.00	1,304.00
Totals	25,350	$3,159.00	$341.50	$3,500.50

The Metric System

Thoughtful business men are giving consideration to the advisability of Canada adopting the metric system of weights and measures when the war is over. It is pointed out by the advocates of the metric system that not only is it employed by such countries as Germany and Austria, who must for many years be the natural competitors of Canada in foreign markets, but that it is also used by friendly European countries, with whom there is a possibility of reciprocal trade arrangements being formed. It is stated that even now German and Austrian factories are piling up stocks of materials manufactured on metric terms of weight and measurement, and that these will be thrust on outside markets just as soon as peace has been declared. To meet this competition successfully and avoid confusion, a uniform system of weights and measures would seem to be a necessity.

Advances in Mechanical Filtration

Improvements in the Art of Rapid Sand Filtration in Constructional Design and Automatic Control Devices

By Thos. Fleming, Jr.*

MECHANICAL filtration or rapid sand filtration, as it is sometimes called, is an American invention, and first made its appearance in 1884. Previous to this, the European method of slow sand filtration had been introduced in this country at several places and was accepted generally as the only method of properly filtering a public water supply on a large scale. This method involved large areas of artificial sand beds which were quite expensive in construction and were beyond the means of many of the small communities and paper mills which were beginning at this time to demand filtered water supplies for contaminated and muddy water. The mechanical system, as proposed, consisted of small tubs or tanks usually containing a three-foot bed of sand through which the water was passed at a high rate of filtration after it had been treated with a coagulating chemical. This chemical was added to the raw water before reaching the filter and formed immediately an artificial gelatinous film over the surface of the sand, thereby collecting most of the foreign material on the surface and preventing a clogging of the filter. These filters were cleaned at frequent periods by reversing the current of water through the manifold in the bottom of the filter and washing the collected suspended matter out of a waste-way near the top.

During the next ten years after the appearance of this type of filter, quite a few of these plants were installed mostly for paper mills and small towns. The results obtained appeared to be more those of clarification than purification and there does not appear to have been much study in scientific operation. It was mainly a commercial proposition floated by private companies under the Hyatt patents with no expert supervision as to the operation or results obtained, and the result was that many of the plants proved unsatisfactory and this type of filtration was regarded as a cheap makeshift method to be used only when the cost of the slow sand system rendered it prohibitive.

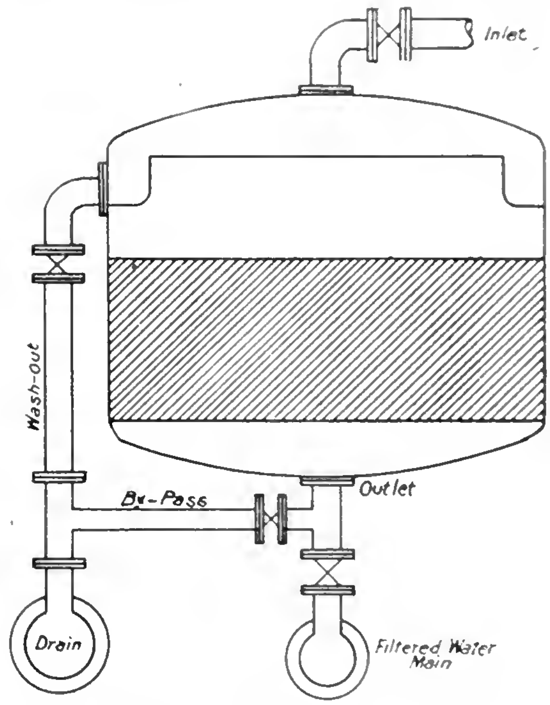
The facility with which clarification could be obtained by this method and the comparative expense and difficulty of accomplishing the same result by any other method, led, however, to the installation of this type of filter plant in quite a few important towns. These plants were built without settling basins along the lines of the first installations and it was soon found that they could not handle the water in these localities during periods of high turbidity. These plants were owned by private corporations, who made efficiency their highest aim in operation and experiments were immediately started in settling the water so as to reduce the load on the filters. It was found that coagulated water could be effectively settled in comparatively short periods of time, thereby greatly reducing the load on the filters during periods of high turbidity, and adequate settling basins were soon added to all of these plants, making them pioneers among the successful mechanical filter plants.

In Folwell's well-known book on "Water Supply," issued in 1900, we find the following statements concerning filtration:

"The efficiency of English sand filtration is thought to be exceeded by that of no other system. . . . . For removing bacteria and other organic matter, English filters give the best results; although mechanical filters with coagulation have given an efficiency only one-half to two per cent. less. But the possibility of occasional serious lapses in full efficiency is greater with mechanical than with English filters."

Several of the other authorities took this same attitude, and generally speaking, slow sand filtration was looked on as the only highly efficient method of filtration at this time. This is not strange considering the conditions under which mechanical filters had been developed, and also the fact that slow sand filters had been in successful use in England and on the continent for some time.

It is an interesting fact that in 1900, less than two million people in America were supplied with filtered water, while to-day we have approximately twenty million people supplied, and of this number, fourteen million, or two-thirds of the people supplied by filtered water obtained it from mechanical filters. The increase in the ratio supplied by this system has been most rapid in the last ten years. In 1900, there were less than one and a half million people supplied by this method; in 1910, this was increased to seven million, while in the last five years, the increase has been one hundred per cent. and there are now over six hundred mechanical filter plants in the United States and Canada.



General Arrangement of a Mechanical or Rapid Filter.

While the experimental work of trained specialists in the last decade has placed this method on a sound basis, yet its success must be attributed to a great ex-

* Before the Engineers' Society of Western Pennsylvania.

tent to the development in the design of these filters and to the scientific control of operation. Municipalities were loath to consider filter plants of this type as long as they were controlled by a basic patent, but when the Hyatt patents expired in 1901, it opened up the field of competition and it was possible to prepare a design on which competition could be secured. Then, too, it was discovered that mechanical filtration, in addition to being cheaper in first cost and operating cost than slow sand filtration, was better adapted to a wide range of conditions, and with water containing a large amount of fine suspended matter could be used with success where the slow sand filter would be doomed to complete failure.

It is not the intention to convey the impression that mechanical filters will entirely supersede slow sand filters, for there are certain conditions where the latter are undoubtedly better suited, but for the surface supplies of the main portion of our country which are subject to wide fluctuations in turbidity, the modern mechanical filter plant will give the highest efficiency and at the lowest cost, not only in first cost, but also in operation.

The large number of filter installations in the last fifteen years which, as we have just pointed out, has increased the number of consumers of filtered water from two million to twenty million, cannot be attributed so much to the improvements in the art of filtration as to the necessity for pure water supplies and the awakening of public interest in such matters. The rapid development in the science of bacteriology and the resultant studies of waterborne diseases have in the last few years focused public attention on polluted water supplies and created a demand for pure water.

The most important improvements in mechanical filters which distinguish the modern plant from the type of plant constructed fifteen years ago, may be classified under the following headings:

Permanent type of construction.

Adequate settling and coagulating faculties.

An accurate and adjustable filter control.

Accessibility and uniform distribution of collecting systems.

A self-cleansing wash system.

Reliable control of chemical feed.

Hydraulic operating valves, and recording devices.

Expert supervision.

Under these general headings, it is proposed to discuss the various improvements.

Permanent Type of Construction

Previous to 1900, mechanical filters were built of wood or steel. If of the gravity type, they consisted of circular tubs of various designs, some containing the filter only and some consisting of double deck structures 16 feet high, the upper 8 feet holding the filter and the lower 8 feet being utilized as a small coagulating basin. Many of the plants consisted of pressure filters looking very much like steel boilers in which the filter was constructed and operated under pressure. Usually the filters were installed on the supply main from the pumps to the distributing system. As a result of the experimental work previously outlined, it was clearly demonstrated that it was impossible to operate pressure filters on contaminated waters with any guarantee of a uniformly high efficiency. It was found, after a certain loss of head is developed by the friction in passing through the filter, that there is a tendency for the surface film over the sand to break, and as this film is mainly responsible for the retention of the bacteria, the filter under such conditions would become merely a strainer retaining the suspended material but permitting the bacteria to enter the filtered water. Further, it was found impossible to get the operators to make the necessary daily inspections of the filters to determine the condition in which they were and to properly govern the washing and cleaning. The result was that the pressure type of filter was discarded as unsuitable for this purpose. The steel and wooden tanks had a comparatively short life, and with the adoption of reinforced concrete for construction work, it was natural that designers in filtration work should turn to this type of construction for the filter tubs. This permitted the construction of rectangular filters in larger sizes and of a shape more adapted to economizing on space.

To-day, the reinforced concrete type of filter can be constructed more cheaply than steel tubs, as has been demonstrated on bids taken both ways on several recent installations. Wooden tubs can, of course, be constructed more cheaply and are still used in temporary installations or in extreme cases where first cost is vital. Practically all of the plants which have been constructed in the last ten years have been of the reinforced concrete type.

There has also been a great change in the quality of the equipment. Flanged cast iron pipe is now used inside of all structures on pressure lines. Reinforced concrete floors have displaced the old wooden operating platforms and the clear wells are now covered with the same type of construction and sealed to avoid contamination. Many of the older plants can still be found, however, where the clear well below the filters is covered by loose boards which form a hazardous protection. Fire-proof buildings for housing the filters, coagulant apparatus and equipment are now the universal standard, where formerly frame structures were not infrequent. In the more recent plants attention has been given to the architecture and to obtain a pleasing and neat appearance in the surroundings.

What has been said concerning the filters also applies to the settling basins. The wooden and steel tanks formerly so common have given place to reinforced concrete basins, carefully designed.

Adequate Settling and Coagulating Facilities

The originators of the mechanical filters paid very little attention to preliminary settling. Most of the early plants installed provided at the most a half hour period of settling and this appears to have been given mainly to secure a thorough coagulation of the water before it reaches the filter. The filter was supposed to do all the work, and it is surprising that the system was as successful as records show.

There are many plants in operation to-day where the settling basins do 90 per cent. of the work during periods of high turbidity, and it is found that in addition to taking out the suspended matter, about the same per cent. of bacteria is removed, presumably by being taken down with the settlement of the coagulated suspended matter.

The average filtration plant to-day is provided with a period of at least four hours of settling with coagulants, and unless there is considerable coarse suspended matter in the raw water at times, no preliminary natural settling is provided. The settling basins are designed in duplicate so that one basin can be cleaned during a favorable condition of the water without closing down the plant. The modern settling basin is constructed of reinforced concrete and the bottoms are sloped with a sufficient grade to permit of the natural flow of the solid matter to a central drain which is controlled by a valve from the top of the basin. A pressure line with hose connections is provided for flushing down the sides and bottom. In the northern latitudes, the basins are covered with reinforced concrete to prevent trouble from freezing during the winter period.

A coagulant is usually fed into the raw water at a special mixing compartment before entering the basins. This compartment is also constructed of concrete and equipped with adjustable wooden baffles which can be set close together in rows and adjusted so as to secure a thorough mixing of the water and chemical before it enters the basins. The entering water must be distributed uniformly across the inlet end of the basin and the basins must be sufficiently baffled to prevent any cross currents. Where two or more basins are constructed, they are often arranged to operate in parallel or series.

A Self-Cleansing System

Many filtration plants have suffered from an operating point of view due to a lack in proper facilities for thoroughly washing the filters. In the old types of filters, very little attention was paid to trough spacing and to the carrying height of water, but most of these filters were provided with mechanical rakes which thoroughly stirred up the sand during the washing period. When the modern concrete type of filter began to be adopted, agitation of the sand by compressed air was substituted for the old type of rakes and more attention was given to providing an adequate amount of wash water. This was limited usually to 8 gallons per square foot per minute, as it was found that a greater amount would disturb the gravel underlying the sand which was usually a small sized gravel ungraded and placed to a depth of eight or ten inches. Under these conditions and with the size of filter sand usually used, the trough system was placed at a height of 15 inches, which was found sufficiently high to prevent the overflow of sand. More recent experiments have shown that a more effective wash can be obtained by eliminating the mechanical agitation and cleaning the filter with a rate of wash of 15 gallons per square foot per minute, which is almost twice the rate formerly adopted. When a filter is washed at this rate, it is found that the entire sand bed is floated, the finer sand being lifted from 24 inches to 30 inches above the normal surface of the sand, and the wash troughs must therefore be constructed at this height. This system was first installed in the Cincinnati, Ohio, plant and gave great success, not only in thoroughly cleansing the filter, but in a lower operating cost and with a less amount of wash water. The trouble from the disturbing of the gravel was eliminated at Cincinnati by tying down the gravel to the bottom of the filter with a bronze screen. Recently it has been discovered that by grading the gravel and using a depth of from 15 inches to 24 inches and by controlling the flow of wash water so as to slowly and uniformly start and stop the wash that it is unnecessary to tie down the gravel in the filters, and several of the latest installations have been installed on this basis.

In connection with the washing of filters, apparatus for removing and replacing the sand by water carriage is of considerable value. Theoretically it should be unnecessary to remove or replace sand in a well operated filter for several years, but in the practical operation it has been found necessary to remove the sand much more frequently, due to displacement of gravel by carelessness of operator in applying the wash water, stopping up of the strainer system with sand, or stopping up of the manifold system or for various other reasons. While the cost of removing sand by hand from a mechanical filter is very small when compared with slow sand filters, yet a considerable saving in operating cost can be effected by installing a water carriage system. This requires a portable hand ejector, a small pressure line and a sand line, both located in the pipe gallery and arranged with outlets opposite each filter. The ejector is placed in the filter when sand is to be removed and connected by hose to the pressure and sand lines in the pipe gallery. The sand can then be removed to a storage bin or to another filter as may be desired.

Reliable Control of Chemical Feed

Many of the older types of filter plants made no provision for an accurate arrangement for feeding the coagulant solution. The material was dissolved in tanks many of which were entirely inadequate in size to enable the operator to use a dilute solution, and the method of operation consisted in dissolving so many pounds of coagulant and feeding this solution into the raw water in a certain period of time, depending upon the turbidity of the water to be treated. The outlet valve was opened a certain number of turns to give this desired rate, and a uniform feed by this approximate method was used.

The filter designers in the last few years have entirely revised this system of applying the coagulants, and most of the modern filter plants of any size have not only an adjustable feed for the chemical solution, but also an automatic arrangement for supplying this feed in direct proportion to the quantity of raw water being admitted to the plant, and further, electric alarms are being installed to immediately sound a gong in case of a stoppage in the flow of the chemical solution. Many of these arrangements are based upon a control from a Venturi meter on the raw water line, while an adjustable orifice enables the operator to set the desired rate of flow of the solution. The electric alarm is usually installed at the orifice and is of simple construction consisting of dry batteries and an open circuit which is closed at the orifice when the liquid fails to flow. The modern solution tanks are usually constructed of reinforced concrete and of ample size to provide sufficient storage for the solution under maximum conditions. They are provided with stirring devices driven by motors located on the operating floor above the tanks.

Hydraulic Operating Valves and Recording Devices

Most of the larger filter plants of recent construction have been equipped with hydraulically operated gate valves controlled from an operating table located in front of each filter. By means of levers on these tables, a valve can be opened or closed very quickly without the labor required on hand operated valves. This method of control is not only justified from an operating point of view in the reduction of operating expense, but also is valuable as affording a quick arrangement for manipulating the plant. The increased cost of equipping a filter with this apparatus is approximately $400 per filter, and the tendency to-day is to apply this equipment to even the smaller installations. The use of recording devices in the larger plants is essential and in the average plant can be judiciously used to advantage. It is inadvisable to overload a plant with recording apparatus on account of the increased cost from an operating point of view in adjusting and keeping up the records.

Building Conditions in Winnipeg

The Metropolis of the Middle West—Housing and Town Planning Associations — Limit Height of Buildings

By Arthur A. Stoughton, R.A.I.C.*

WINNIPEG has passed so rapidly from the frontier village stage, with all that that term connotes of shacks and mud and primitive society, to the dignity of a well-ordered city, with large and handsome buildings; having become a large producing and distributing centre, with an extensive banking system and all the features of the political society, that it is necessary to check up its status and achievements at frequent intervals in order to keep informed of its progress.

This is specially necessary for contractors and material men and manufacturers, both in the city and those at a distance, whose products are used there, lest its demands and the amount of commodities it can absorb and the opportunities it presents be underestimated. When we are faced with the fact that the year before the war, 1913, saw $12,000,000 worth of buildings erected there, which was one-quarter of the cost of new buildings for that year in New York city, we have to admit that Winnipeg is no mean city for the contractor. The Industrial Bureau, under its able head, Mr. Chas. H. Webster, acts as a clearing house for information and statistics, which I need not reproduce here, and a stimulus for the increase of manufactures and business in general, and, therefore, is an important aid to the activity of the contractor. The growth of Winnipeg in population and wealth is one of the most remarkable chapters in the history of civic development on the continent.

Present Conditions

As elsewhere, present conditions have put a quietus on most of this activity, but with the return of a normal state there will surely come a great expansion of business. Immigration of a good class will result from the devastation of the war and thousands of those whose homes and villages have been destroyed and others who prefer our peaceful prairies to the uncertainty of life in parts of Europe will settle here and around us. More acres will be tilled; more individuals will buy necessities and luxuries; more things will be produced; more money will circulate, and therefore more building will be done. The manufacturing of war material now and the feeding of Europe now and later will aid the general prosperous movement.

Even during this year many new industries have been started here and industrial plants erected. What may not be expected in increase in business as soon as the war is over? All should look to the future and consider plans for the handling of a larger volume of building work.

Winnipeg has already a good equipment of factories for the production of many of the building materials, iron, steel, woodworking, etc., and there are natural resources in the province of various building stones and timber and materials for good bricks and cement. The Tyndall limestone with a fossiliferous mottling is an excellent wearing and appearing limestone, used on very many of the best buildings. A fine dolomite has been recently found and is about to be put on the market. The "Made-in-Winnipeg" slogan has helped to create more home products, such plants being made possible by the increasing size of the city and its requirements, while very many eastern and foreign concerns have agencies here, some with their own local shops, at least for assembling.

It is an assured fact that Winnipeg will always be the metropolis of this whole middle country, acting as distributor and banker and clearing house and the transportation centre and labor market, and to a great extent, manufacturer, so that industries and business of every kind will concentrate here, as railways have already done. This means the greatest population and all those material needs which accompany size, growth, and activity. For the contractor it spells building of every kind—commercial houses, vast plants, school and public buildings, modest and expensive houses, bridges, railways and engineering structures of every kind.

Co-operation

The contractor should co-operate with the architect as a helper in this great building enterprise. As soon as society passes the primitive stage man seeks to order his building with a view to its agreeable appearance, which gives scope for the architect as distinguished from the mere builder or constructor. Anyone passing along the streets of Winnipeg will notice that the architects responsible for their appearance are men of taste who love their art. The architects of Winnipeg are a well-organized body who have secured the enactment of a good law which requires a high standard of training and experience in those who are admitted to practice. The architects meet informally at a weekly luncheon, which is addressed by some professional man on a subject more or less related to architecture. There are examples of the work of Eastern Canadian and American architects in the Fort Garry Hotel, the Union Station, the Bank of Montreal, and other fine buildings. It is well to have such buildings for variety and inspiration, but many buildings by local men are not a whit inferior to these. Not content with the recruiting of the profession from architects' offices or distant schools, they have succeeded in inducing the University of Manitoba to undertake this professional training. Two years ago a Department of Architecture was organized and a four years' course, similar in scope to those in Canadian and American universities, was inaugurated, in which construction and design are given equal weight, and the work is now proceeding favorably.

The University of Manitoba has grown so that it is crowded in its present buildings and is looking forward to occupying a fine new site for which an extensive group of buildings has already been projected. In connection with the Department of Architecture, an evening class for draughtsmen has been carried on with excellent results, so that, for a nominal fee, men engaged by day in offices can become designers and learn better rendering of drawings by working in this evening class. The new Art School of the Industrial Bureau provides good instruction in drawing and painting. The work of the Art Club, the Western Art Association, the Archaelogical Institute and the exhibi-

* Professor of Architecture in the University of Manitoba.

tions of paintings in the Art Gallery are all influential in raising the standard of art and culture which contributes to better building.

A great deal of construction has been going on, started before the war, such as the great Parliament Buildings, the Law Courts, the extensive group of the Agricultural College at St. Vital, each costing several million dollars, the Children's Home, the Fort Garry Hotel, and the enlargement of the Royal Alexandra Hotel, the Bank of Quebec, the Coco-Cola building and a large number of smaller business buildings and residences. The Ford Motor Company has just finished a large building as an assembling plant, in the west part of the city, on Portage Avenue. The Bank of Montreal is starting a very fine and handsome building, on Main Street, adjoining the Canadian Bank of Commerce. The Grain Exchange is adding several stories to its building. A group plan for the University was prepared and drawings for the first building, for engineering and architecture, made, which awaits more settled conditions for its development. Along Portage Avenue business buildings, large and small, have been erected, and all over the city houses and apartment blocks have sprung up in every direction.

Huge Department Store Buildings

The most important event in the building line, however, is the commencement of huge buildings by the T. Eaton Company to house their store and mail order business and to be their main distributing house for their Western Canada trade. They will cover two entire blocks between Portage and St. Marys Avenues and Hargrave and Donald Streets, having twelve high storeys, rising to a height of 215 feet, connected at every storey above the second by two bridge structures, spanning Graham Avenue, and under the whole of that street. It will be built in units of one-quarter of a block, eight storeys high, one each year for the next eight years, each costing approximately $600,000. When both blocks are thus covered to a height of eight storeys, the upper four storeys will presumably be built in the same way. The south building will be first constructed. The first unit, at the southeast corner of Hargrave Street and Graham Avenue, is now well along. The present store will be replaced only after the south building has been carried up the eight storeys. This great enterprise, undertaken in times when every person is inclined to delay expenditure, shows the confidence in the future of this city and the western country on the part of very sagacious and far-seeing men. It will inevitably be a powerful incentive to others to build, and it will tend to raise the whole tone of business and increase optimism.

Limit Height of Buildings

About a year ago the city passed a by-law limiting the height of buildings, which would have a far-reaching effect in preventing concentration of high buildings and real estate values in a few spots, to the detriment and impoverishment of other districts and in tending to keep down values to a reasonable figure and in equalizing and spreading business and traffic. It prescribes that buildings shall not be more than one and three-quarter times the width of the street in height and not more than 198 feet nor more than twelve storeys in height on any street. Nearly all Winnipeg streets are 66 feet wide so that on them buildings would not be more than 115½ feet high. Main Street, Portage Avenue, and Broadway are each 132 feet wide. On these, a building may not be more than 198 feet high, or one and one-half times the width of the street, but as it may not have more than twelve storeys, all ordinary buildings would be about 165 feet high, which is the height of the McArthur Building, on Portage Avenue, near Main Street, the highest, at present, except the Fort Garry Hotel, whose steep sloping roofs are 200 feet high. Any buildings on these side streets, needing very high storeys, could have twelve of them within 198 feet.

When the T. Eaton Company presented its proposal, as outlined above, to two buildings of equal height, the one on Portage Avenue being slightly higher than the limit for 132 foot streets, the one on the south block being one hundred feet higher than the limit for 66-foot streets, on four of which it faces, the City Council suspended the by-law to give special permission, and another exception was made a few weeks later to enable the Grain Exchange to add several storeys to its buildings, as originally planned. In view of these facts it seems highly improbable that this very desirable height limitation will be adhered to.

Winnipeg is most fortunate in the openness of its street system. Few cities in Canada have such an asset in wide main streets for business, and beautiful river scenery for residential districts, as well as the fine appearance of a great number of the residential streets. These are 66 feet wide with a 24-foot roadway, the remaining space being devoted to wide boulevards, well planted with grass and shaded by trees and maintained with assiduous care by the Parks Boards. There are a number of exceptionally fine residence districts, while the districts where the working people live are equally open and free from slums of the ordinary type.

House and Town Planning

The city seeks to improve its plan and provide for proper development in the future as well as co-ordination of its street system with that of the surrounding municipalities. It has had for some time a Housing and Town Planning Association and it now has a Committee of the Industrial Bureau of Town Planning and Civic Betterment to further schemes for improvement in various civic lines. It has appointed a permanent body known as the Greater Winnipeg Plan Commission to take in charge officially the work of planning and re-planning. This Commission is now preparing a comprehensive plan of the whole district, for the city to work to as the time goes on, and it is considering suggestions for individual changes, modifications or additions to the present plan where it is defective and where needed by new conditions of increased business, traffic, etc., to improve circulation, reduce friction, and further economy of transit. It will cultivate co-operation with city and environs as to through avenues; it will lay out a general park system and will provide for small parks and recreation spaces through the settled areas. Its task is a mighty one, as the city is so large—the area of Greater Winnipeg being 200 square miles—and there has been subdivision so far beyond settlement, but with the cordial support of the officials and the people, it hopes to make Winnipeg the finest city of the future in Western Canada, as it will be the largest and most important. Mr Thomas Adams, the Town Planning Advisor of the Commission of Conservation, visited it recently and made suggestions, but he said that it was already well provided with fine broad avenues for its main arteries.

A provincial town planning act was passed at the last session of the Legislature which gives to cities, town and municipalities greatly enlarged powers in the use of land in town planning schemes and for public purposes generally, and furnishes the procedure by which they may initiate plans and execute improvements. Already some are preparing to take advantage of these powers.

The Commission has, at the city's direction, provided the architectural treatment for several bridges, drawings for which were made by Mr. Paul Schioler, then City Bridge Engineer, which, if constructed, will be a series unique in Canada, in that engineer and architect have collaborated in designing bridges suitable in structure and agreeable in appearance. They will have no unsightly trusses and plate girders and bascule counterweights even are kept below the roadway, so that the piers and pylons, balustrades and lamps are treated entirely with regard to their aesthetic effect.

The economic problem bears heavily here as elsewhere, the army of the unemployed having mobilized here more numerously because Winnipeg is a larger city and because its extensive relief work is so well advertised. Many have suggested that its wisest relief work would be the undertaking of public construction; that it should pay wages instead of charity, and in so-doing it would add very little to the tax rate. The city is economizing to the last degree, reducing public expenditures, cutting down staff and avoiding all outlay in improvements which can be deferred. Perhaps this is penny wise and pound foolish. For improvements which will benefit the city of the present and future, debentures could be issued, with due regard to the life of the improvements. Future generations in their more prosperous times, would help to pay for what we should construct in these troublous times. Thus would present times be improved by the property created by construction and the circulation of money; unemployment would be relieved; advantage would be taken of low prices, and the burden to the present generation would be negligible in amount.

Waterworks and Sewerage Systems

of Canada, Statistically Reviewed in Recent Government Report—Some Typical Illustrations

THE Commission of Conservation of Canada have just issued a new edition of their book, "Waterworks and Sewerage Systems." A previous edition was prepared in 1912, in which it was aimed at presenting in a form readily available for reference, the principal physical data respecting the waterworks systems then in existence in Canada. The present report brings the waterworks systems up to date, and in addition, summarizes the sewerage systems.

The importance of sewage disposal can be readily appreciated when we consider the number of inland bodies of water which receive raw sewage and at the same time are the only available source of water supply for certain municipalities in the neighborhood. The supply of water to these communities is the most important use of these lakes and rivers and the value of a pure supply as compared with one polluted by sewage can scarcely be overestimated. Even where water systems are provided with filtration plants, there is great danger of overloading the filter if the source of supply is grossly polluted by raw sewage. The use of water filters should be only an additional factor of safety in an operation which should begin with the proper treatment of sewage. A well-known Canadian authority on municipal engineering has advanced the statement that, "if the domestic sewage which now discharges, by means of underground sewers, directly into streams, rivers, and lakes, without any form of treatment, were treated to the extent of the elimination and destruction of the sewage bacteria, at least fifteen hundred lives could be saved annually in Canada from death by typhoid alone."

The Commission's report refers to water purification by hypochlorite of calcium, which is being very freely adopted in America. Much has been said for and against the hypochlorite or similar treatment. It is recognized however, that as a solitary treatment to obtain pure water it cannot be considered a permanent method. While it would be most unwise not to immediately resort to this treatment in cases of emergency, its usefulness should end there. One of the principal objections to its permanent use is the "residual chlorine" taste or odor acquired by the water in this treatment. It is the opinion of certain authorities on water-purification that to be certain of the destruction of all bacteria, such an excess of the chemical is necessary as to be noticeable to the smell and taste; or vice versa that if there is no smell and taste in the purified water the bacteria are not destroyed with certainty.

A number of interesting illustrations are included in the report, some of which, through the kindness of the Commission of Conservation, we are reproducing in this issue. They are typical of the methods adopted in water supply and sewerage disposal throughout the Dominion of Canada. The following data refer to the waterworks or sewage systems of the towns to which one or other of the various illustrations refers:

Waterworks

Hamilton—Supply pumped from Lake Ontario, 5 miles distant, into mains; electric power used, with steam auxiliary plant, average 1,200 h.p., maximum, 1,500 h.p. Reservoir: emergency reservoir of 11,000,000 gal., and three others of 2,000,000 gal, 300,000 gal., and 80,000 gal. capacity respectively. Purification: settling basin used. Distribution: 179¾ miles of C. I. mains, 4 in. to 36 in.; 1,782 hydrants; 27,234 services, lead pipe. Pressure: ordinary, 75 lbs.; fire, 60 to 100 lbs. Consumption: 13,500,000 gal. Financial: total cost of plant, $3,466,156; annual maintenance, $117,054; interest, $99,505; revenue, $289,587. Rates: flat rate, on assessment basis up to $4 per $1,000; bathroom, $2.00; meter rate, 7½ cents and 10 cents per 1,000 gal. Officer in charge, A. F. Macallum, city engineer. (Since resigned).

Berlin—Supply pumped from artesian wells, 2 miles distant, to stand-pipe; electric power used with steam and gasoline auxiliary; maximum, 470 h.p.; average, 75 h.p. Reservoir, stand-pipe of 500,000 gal. capacity, illustrated herewith; storage reservoir,

of the sewage being treated in a septic tank. Cost of sewers, $3,890,363.

Lethbridge—29 miles of separate sanitary sewers and 2¾m. of storm sewers. The sanitary sewers are divided as follows: ¾ m. of 18 in. x 18 in. wooden box, outfall sewer; 1½ m. of 24 in. vitrified pipe; 3 m. of 15 in. to 22 in. vitrified pipe; 8¼ m. of 10 in. and 12 in. vitrified pipe; 15½ m. of 8 in. vitrified pipe. The storm sewers range from 15 in. to 30 in. The sewage treated in sedimentation tanks, sprinkling filters and chlorinated, the outlets discharging into Belly river; cost of sewers, $275,203; cost of disposal plant, $90,000.

Toronto—total of 480 miles of combined street and domestic sewers, of which the larger ones may be divided as follows: 11 m. of 6½ ft. to 9½ ft. circular; 8 m. of 4¼ ft. to 6 ft. circular; 6 m. of 2½ ft. to 4 ft. circular; 3¾ m. of 6 ft. x 6 ft. to 10¾ ft. x 10¾ ft. culvert type; 9½ m. of 2 ft. x 3 ft. to 5 ft. x 6½ ft. culvert type; 1½ m. of 4 ft. x 6 ft. to 4¼ ft. x 6½ ft. egg-shaped; 3¾ m. of 3 ft. x 4½ ft. to 3¾ ft. x 5¾ ft. egg-shaped; 2½ m. of 2 ft. x 3 ft. to 2¾ ft. x 4¼ ft. egg-shaped. Both concrete and brick are used in the construction of these sewers, the sanitary sewers generally having a vitrified wearing surface of either glazed tile or brick. For sewers carrying storm water only, concrete construction is considered as efficient as any other and cheaper. The larger sewers above enumerated give a total of 46¾ miles, the remaining 433 miles are of 12 in. to 24 in. tile type. The sewage is treated by chlorination and in sedimentation tanks. Cost of disposal plant and trunk sewers in connection with it, $2,792,000.

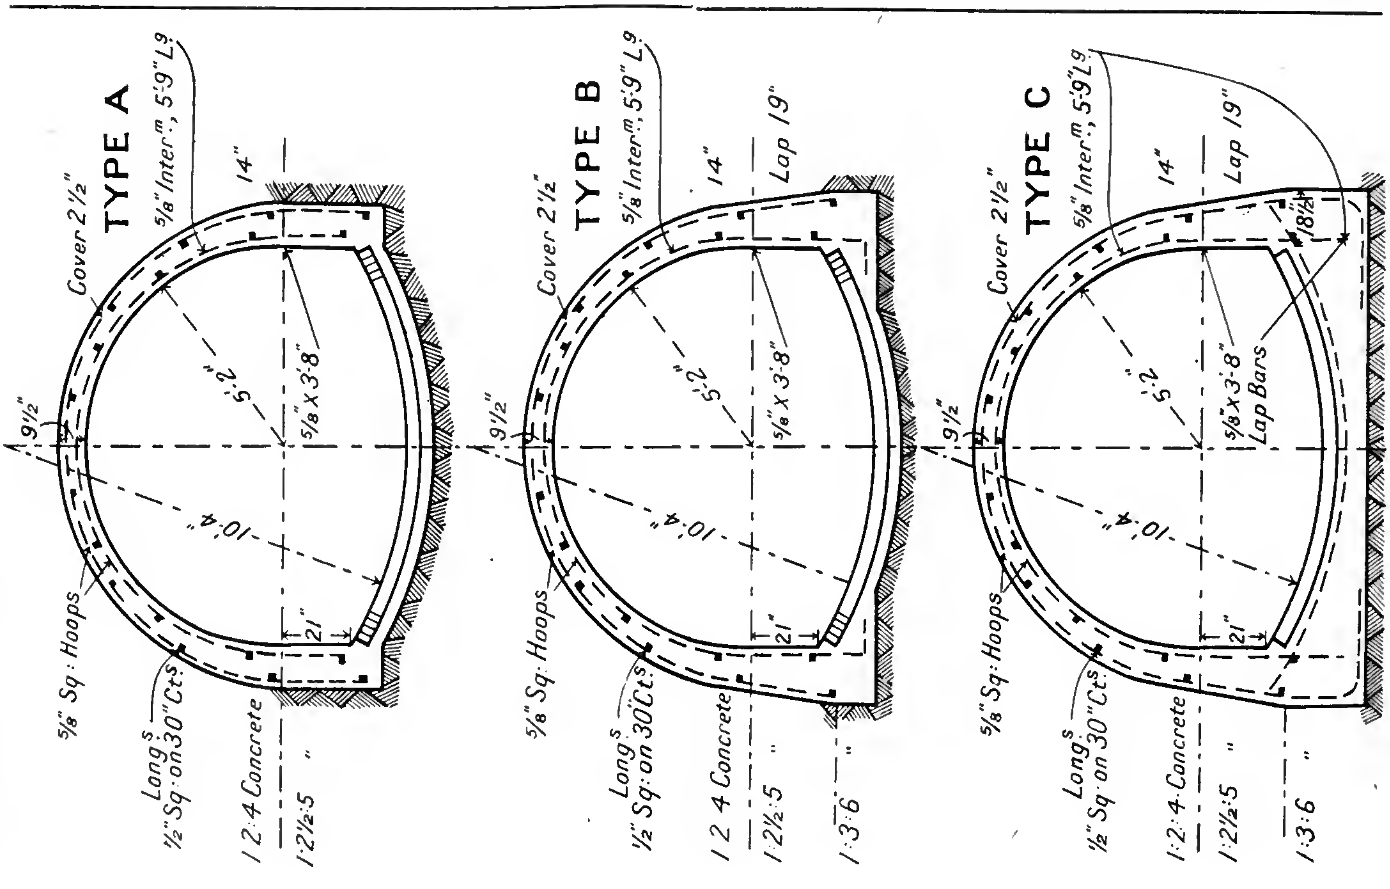
Winnipeg—total of 255¾ miles of combined street and domestic sewers, which are divided as follows: 4 m. of 8½ ft. x 6½ ft. to 14 ft. x 9½ ft. egg-shaped, concrete; 10¼ m. of 6 ft. x 4¾ ft. to 8 ft. x 6¼ ft. egg-shaped, concrete; 7½ m. of 4 ft. x 3 ft. to 5¼ ft. x 4 ft. egg-shaped, concrete; 4¼ m. of 2 ft. x 3 ft. to 7 ft. x 5½ ft. brick; 6½ m. of 2 ft. to 5 ft. brick; 1¼ m. of 2 ft. to 3ft. circular concrete; 90 m. of 15 in. to 22 in. vitrified pipe; 106¼ m. of 12 in. vitrified pipe; ¾ m. of 9 in. vitrified pipe. There are 14 outlets emptying into the Red river and 9 into the Assinaboine river. Cost of sewers, $4,079,053.

Vancouver—200 miles of sewers, the greater part carrying combined street and domestic sewage, with outlets into the Pacific. They range from 6 in. to 84 in. circular section and horse-shoe section equivalent to 10¼ ft. circular, the material being vitrified pipe, cement pipe, concrete, with or without brick or vitrified tile lining. Approximate cost of sewers, $4,500,000.

Stratford—total of 34¾ miles of sewers, part carrying combined street drainage and domestic sewage, part carrying these separately. The sewers may be divided as follows: 2¼ miles of 36 in. and 48 in. circular, concrete; 2¾ m. of 18 in. to 24 in. circular, vitrified pipe; 4 m. of 12 in. and 15 in. circular, vitrified pipe; 24½ m. of 9 in. and 1¼ m. of 8 in. circular, vitrified pipe. The sewage is treated in septic tanks and sprinkling filters. Cost of sewers, $50,000; cost of disposal plant, $60,000.

Nails driven in wood that is exposed to alternate wetting and drying are liable in time to start to work out. The wetting swells the wood and increases its dimensions across the grain, and as the nail is inelastic it is moved, a space forming at the point equal to the amount of swelling of the wood. When the timber dries the nail does not return to its original place, and if tapered it tends to move outward each time that wood is wet and dried. It is for this reason that wood structures bolted together and exposed to the weather require screwing up at intervals.

Messrs. Prack & Perrine, architects and engineers, have moved their office from the Traders Bank Building to room No. 808, Lumsden Building, Toronto, Ont.



Typical Sections Balaclava St. Trunk Sewer, Vancouver, B. C.

The Care and Operation of Belts and Ropes in a Contractor's Outfit

ENGINEERS and contractors who have much to do with the buying and supervision of belts should attend to the little things in their care and operation; they are really more important than the buying. The trouble is that most contractors after buying the belt they believe to be the "best" for their service, hand it over, without further thought, to the foreman, who hacks it up. He pays too little attention, perhaps, to the lacing of the belt or the dressing that should be used to keep it in good pulling shape. Engineers and contractors would do well to pay more attention to how their belts are lined, laced and dressed. They could generally effect a material saving in their plant, as belting is expensive.

Requisites for Good Belts

Manufacturers advise operators to run belts as slack as possible, because, with proper care, they will transmit the necessary power better. The old cast-iron rule of having all belts tight is being done away with and engineers are learning that tight belts are not always essential for the most efficient belt operation.

A few qualities to be desired in a good belt are—first, a good driving surface with sufficient friction between belt and pulley to eliminate slip as completely as possible and to enable the belt to carry its load under minimum tension, thus avoiding useless waste due to bearing friction. Second, lateral stiffness, coupled with pliability; stiffness to keep the belt from twisting and waving and to prevent curling at the edges when shifted, and pliability to enable it to hug the pulley; a pliable belt will lie down close on the pulley and bring into active contact every available inch of pulling surface; pliability in a belt allows it to secure the maximum arc of contact and to alter its shape with the minimum of internal resistance as it travels around and conforms to the shape of the pulley; avoid hard, dry, stiff belts. Third, good tensile strength, that it may carry its load without breaking. Fourth, little stretch and considerable elasticity: the former, so that it will not need to be continually shortened, the latter that it may take up or let go its load as it passes around the pulley. Fifth, firmness and stability, so that the leather springs little when cut, holds its shape, remains straight and runs true around the pulley. Sixth, resistance to external conditions, such as heat, moisture, chemicals, etc., that it may work in any place at any time and wear enduringly. Seventh, low cost.

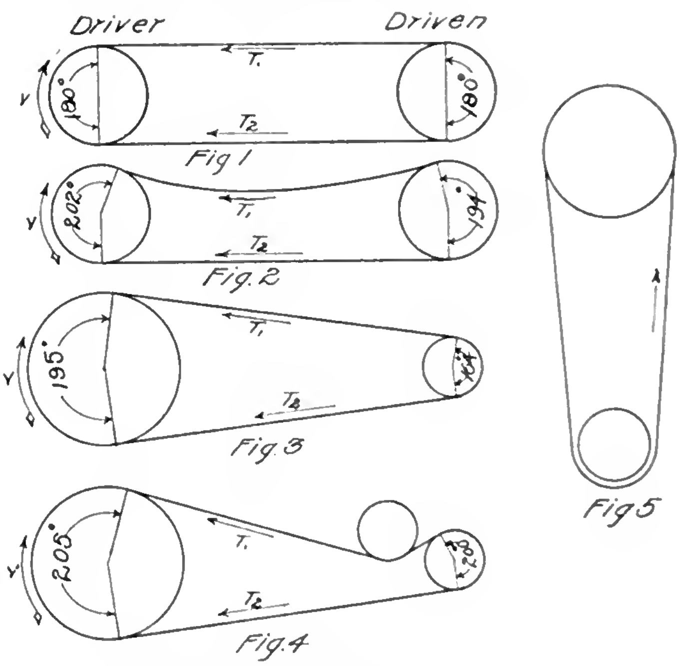
These, of course, if one hundred per cent. efficient, constitute an ideal case, but no leather can have all of these qualities in an equally high degree. Sole leather would do admirably as far as lateral stiffness, little stretch, and firmness are concerned, but would fail entirely to satisfy the demand for pliability, tensile strength, elasticity, etc. The best results from leather belting are necessarily somewhat of a compromise.

Care of Belts

The most important item in the care of belts is to keep them from getting hard and dry. On the other hand, trouble is often occasioned by belts becoming oil-soaked and when travelling at a high rate of speed jumping off and destroying themselves. Pulverized lime is very good where the belt is wet with oil or water. Pulverized chalk, phosphate dust, cement, fire clay, or fine ashes, would do as well, the idea being to get the dust to absorb the oil or moisture. The oil-laden dust may be easily scraped off the belt or pulley or it will sometimes roll up in balls and drop off of its own accord. Linseed oil is good for cotton or canvas belts, especially in damp places or warm climates, while neats-foot oil is a very good dressing for leather belts. Care should be exercised in using substitutes for belt dressings, however. The extravagant use of those mentioned may soon ruin a belt. Keep on hand a good belt dressing; it will prolong the life of the belt.

Splicing

The idea that a belt is a belt and that one need merely cut off a piece of the requisite length and put it on the pulley, is no longer tenable. Proper mechanical conditions and adaptation of belt to drive, are just as essential to economy of operation as is the choice of an electric motor to the work it has to do. The trouble with too many foremen is that they look no further than the belt itself.



Belt Gearing for Securing Maximum Efficiency

The splicing of the belt is a big factor in prolonging its life. The endless or cemented belt is the best type, but where it cannot be used handily a lacing that most closely imitates it is the next best thing. Lace joints should be pliable to allow them to hug a small pulley. Belts are cemented more easily nowadays than they were formerly, because of the improved equipment. A belt is simply sliced twice to the proper bevel line, thus cutting out the old splice, cemented, set together and placed under a press. The usual cement employed to stick the laps has for its basis animal glue. This cement will usually hold as long as the leather lasts. Modern waterproof cement is unaffected by either hot or cold water.

There is some controversy as to whether leather or wire is the best for laced belts; whichever under the conditions will most closely approach the condition of an endless belt should be used. Poor lacing is one of the principal causes of belt deterioration.

In leather lacing care should be taken in punching holes. It was often thought that the more lacing, the stronger the joint. This may be true in so far as the laces are concerned, but each extra hole decreases the cross section of the belt and therefore its tensile strength.

The wire joint is fast approaching the desired condition of an endless belt. Wire joints are fairly quiet in operation, can be joined to run without a jump, and are almost as flexible as the cemented joint both laterally and longitudinally. They are almost as strong, too, because little of the belt section is punched away, the wire prongs merely displacing the belt fibres by pushing them aside. Make belts endless or make them approach that limit, as nearly as possible, is a good rule.

Belt Gearing

The average thickness of single belts is 7/32 in., and the weight of the average 7/32 in. leather belting is .0911 lbs. per inch width of foot length. The maximum tension for the driving side of a single belt should not exceed 90 lbs. per inch width for cemented or riveted belts and 70 lbs. per inch width of laced belts.

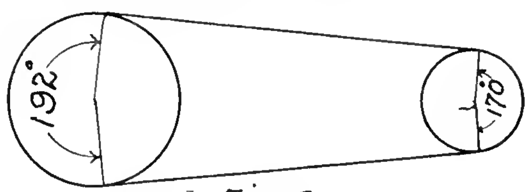


Fig. 6

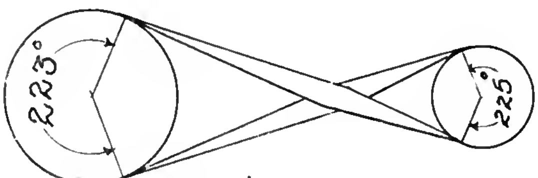

Fig. 7

Crossing Belts to Secure a Maximum Arc of Belt Contact

The allowable maximum velocity for single ply belts is 4,500 to 6,000 feet per second. This velocity may be determined more closely for any particular case by using the formula: $V = 196.5 \sqrt{T_2/w}$. Where V is the maximum velocity, T_2 the tension per inch width for the belt on the driving side, and w the weight per inch width of foot length.

The horse power that a given belt will carry may be found from the formula:

$$\text{H.P.} = \frac{(T_2 - T_1)\,V}{33000}$$

Where T_2 is the tension in pounds per inch of width on the driving side, T_1 the tension on the driven side.

A good approximation for horse power is: bv/870 for cemented belts or bv/1117 for laced belts, where b is the width of the belt. This same equation may be used to approximate the width of the belt required to transmit a given horse power at a given speed.

The following table may be used for determining the horse power that given belts will carry under average conditions.

Single Belts

Width	Cemented	Laced
2 in. to 6 in.	H.P.= bv/1000	H.P.= bv/1300
above 6 in.	H.P.= bv/ 900	H.P.= bv/1000

Double Belts

up to 6 in.	H.P.= bv/500	H.P.= bv/650
6 in. to 10 in.	H.P.= bv/450	H.P.= bv/550
above 10 in.	H.P.= bv/380	H.P.= bv/480

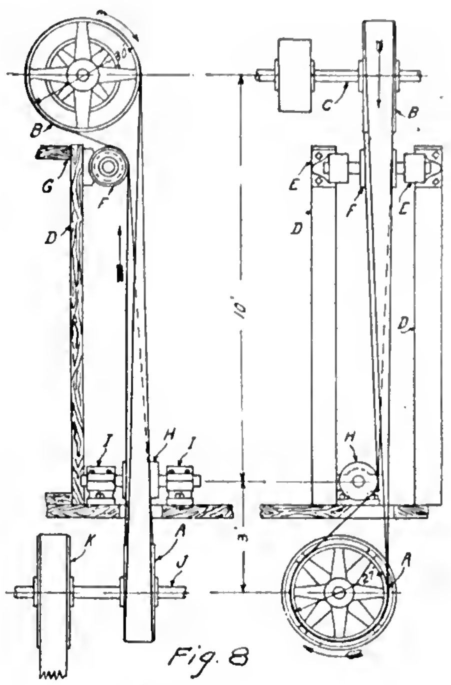
Single belts are not made above 12 inches in width.

Pulley Arrangement

No absolute rule for an ideal arrangement of pulleys can be laid down, but there are a few general rules that should be followed in working out the best arrangement of belt gearing. The driving power of a belt depends on the frictional resistance, F, which depends on the frictional coefficient, f, the arc of contact and the width of the belt. The frictional coefficient, f, depends on the nature of the surface and may be increased by the proper treatment of the belt to make it soft and pliable so that it will hug the pulley surface in passing around it. The arc of contact is probably the most important factor in the efficient operation of belts. Fig. 1 shows an arrangement of pulleys connected by a tight belt running at the same rate of speed. The arc of contact is 180 degrees in each case. If the distance from centre to centre is great enough, a heavy belt running slack may give better pulling power than the tight belt, because it increases the arc of contact, as shown in Fig. 2. A rough rule that may be applied in such cases is that every degree of belt contact increases the pulling power by 1/360. If two pulleys are connected by a tight belt the bearings are under high tension and therefore consume considerably more power than do the bearings in Fig. 2 after the initial tension is relieved.

A great deal may be said, pro and con, for slack belts. In some cases, for instance, where shafts are spaced very closely centre to centre, they will not work, especially if the horse power to be transmitted is considerable. Much depends upon the distance between the shafts, the character of the drive—gas, steam, or electric motors—and the character of the driven machinery. One of the chief advantages of slack belts is the fact that they seldom have to be taken up. Most of the time otherwise spent in splicing is thereby saved.

In such a drive as Fig. 3, where the driven pulley is required to run at a high r.p.m., much trouble will result if it is driven directly by a tight belt from such a large pulley as shown. If the r.p.m. of both pulleys is fixed, an idler should be used to increase the arc of contact, otherwise the percentage of slip may rise to unsafe proportions, as the arc of contact may be only a small fraction of the pulley surface. Fig. 4 shows how the arc may be increased by the use of an idler. Such an idler need not be heavy and need have no additional weights attached. As a rule its own weight is sufficient to effect the desired change. It should, however, be well machined and perfectly aligned, for the ultimate efficiency depends on this accuracy. A well proportioned and properly aligned pulley consumes very little power, but if it is not in good alignment it may become a regular coal consumer and the power gained by the increased arc of contact may not be sufficient to overcome the loss due to poor alignment. In cases where an idler is employed an endless belt should be used, since the idler runs on the opposite side to what the pulleys do. A thick lace joint will cause a jump or jar every time it passes around the idler. Leather belts are best because they can be made endless by cementing.



Method of Making a Quarter Turn with Belts

In vertical drives idlers prove a saving, because with a vertical drive running at a high rate of speed, the centrifugal effect of the belt may cause it to leave the lower pulley face entirely, as shown in Fig. 5, and allow the driven pulleys to come to rest. This centrifugal effect may be overcome by the use of a spring idler.

Another method of increasing the arc of contact is by crossing the belt, as shown in Fig. 7. This method depends entirely, however, on the direction in which the machines have to run.

Transmission Efficiency

Any arrangement that will decrease slip and increase the frictional factor, F, will prove a saving. Belt slip creates friction and where power is consumed through friction either by belt slip, belt creep, journal friction or windage, fuel is unnecessarily spent thereby. Every per cent. of slip costs approximately one per cent. of the fuel. In average belt gearing with a low pulley ratio, the belt slip seldom runs higher than 5 per cent., and with a good gear it averages about 3 per cent. with good belts. This leaves a belt transmission efficiency of 95 per cent. Of this approximately only 3 per cent. is actual slip, the remainder being creep. This creep cannot be avoided, and that is one reason why average leather belting transmission efficiency never runs above 98 per cent. Slip can be avoided, and with well oiled bearings, good shaft and pulley alignment, a well-cared-for non-slipping belt, a belt transmission efficiency of 97 per cent. should be maintained right along.

Care of Manilla Rope

Contractors with extensive equipment necessarily require for its operation a great deal of rope of various sizes and lengths. Possibly there is no article in the contractor's outfit which receives more abuse than manilla rope.

Manilla hemp, of which most ropes are manufactured, at least all rope over 1 inch in diameter, is a vegetable fibre and is susceptible to the action of water and air, the same as a piece of unprotected wood. In fact the hardest wear on a rope is exposure to all kinds of weather. This cannot be avoided in construction work. Contractors would do well, therefore, to pay a little attention to the conditions for preserving rope in service. Ropes in service deteriorate in two ways—by the wear on the outer surface that can readily be seen, and the stretching, bending, crushing and breaking, of the inner fibres that cannot be discerned without careful examination. The wear on the outer surface may be accelerated by ropes rubbing against each other or by dragging across hard surfaces, or by running over sheaves having too small a groove or too small a diameter consistent with the load upon it.

Ropes do not give out all at once, and therefore need much careful attention. Rope failure is more likely to be due to overloading than to any other cause. A rope subjected to overloading will show it by the twist coming out or by the strands jumping out of their proper place. Ropes in service on heavy work, such as pile-driving, steam shovel or crane work, hoisting, etc., should never have the load applied suddenly or with a jerk, because the stress set up in the rope will be many times that of the weight to be lifted, and if it does not result in the failure instantly, will probably cause deformation which will start deterioration. Sudden stress applied to a rope with a kink in it may result in instant failure or in any case will cause a loss of strength. Ropes used on derricks, cranes and pile-drivers, which have to handle heavy loads over small diameter sheaves, wear out very rapidly, while ropes of the same diameter working over large sheaves will handle the same load for years.

In passing over a small sheave the rope is subject to sharp bending which causes the fibres to slide slightly on each other and, being rough, the friction causes them to break. Running a rope over two small sheaves, bending first in one direction and then in the other, necessarily exaggerates the trouble.

Rope that has been wet or muddy should be cleaned after use and stored in a well ventilated place. Wet rope placed in a box or a small unventilated store room is likely to rot or ferment rapidly and become worthless in a short period of time. Tarring ropes may be employed when they are subject to considerable wet and comparatively little stress, but should not be used on ropes on cranes or derricks subject to heavy service, as the tar cracks when passing over small sheaves. A rope should not be allowed to freeze after becoming wet, or if frozen should not be used, because the fibres will break; neither should it be piled against radiators or steam pipes for obvious reasons. On the other hand, a rope may be seriously damaged by becoming too dry because the fibres become brittle.

These are a few conditions which, if guarded against by a competent foreman, will prolong the life of the plant and reduce the operating expenses. In nine cases out of ten, abuse of rope is due more to the lack of knowledge than to wilful neglect.

An effort is to be made to cheapen the cost of laying asphalt pavements in Montreal. Mr. P. Mercier, the chief engineer, has issued instructions that $1.90 per yard is not to be exceeded, this comparing with $2.14 last year. The saving is to be made by more efficient administration.

Foundations and Their Treatment

Bearing Power of Sub-soils — The Design of Different Types of Foundations to Meet Different Local Conditions

By M. T. Cantell

ALTHOUGH from an artistic standpoint the foundation of a structure is a minor detail, yet as regards the stability it is of the greatest importance and demands the utmost consideration and knowledge of the designer.

The kind of foundation necessary for any structure depends upon the condition of the subsoil and its bearing power. If this is not of sufficient strength in its natural condition the soil or the foundations, or both of these,must receive special treatment. The subsoil must have sufficient bearing power to directly support the dead load of the structure plus the pressure caused by external forces such as traffic, moving machinery, wind, earth, water, or other forces to which the structure may be exposed.

Special Treatment for Heavy Buildings

Special treatment is seldom necessary for light structures on ordinary soil that has not been disturbed from its natural condition, but the weight of heavy structures will often greatly exceed the bearing power of the soil upon which they are to be erected, consequently, if the foundations do not receive due consideration settlement will occur and the stability of the structure will be seriously affected; such results are unfortunately very frequent and are in most cases due to carelessness or neglect of the designer or contractor. Faulty foundations, however, are not responsible for all settlements, very many structures large and small have settled owing to subsidences caused by colliery workings, tunneling, sewering, and other work requiring deep excavations. Also by water finding its way to and percolating through the subsoil and gradually draining away the light constituents after the structure is erected.

Variation of Bearing Power of Subsoils Explained

The bearing power of subsoils vary considerably; made-ground simply tipped and spread in position will settle under its own weight about three inches for a depth of eight feet; if, however, the same earth be well pounded in layers it can be made to support as much as one ton per square foot without any appreciable settlement. A layer not less than a foot thick of broken stone well rammed on top of loose earth will support three-quarter ton per square foot. Light earth and sandy loam in their natural condition will support three-quarters to one and one-quarter ton. Wet sandy gravel one and one-half ton. Compact gravel in thickness not less than twice the depth of the footings will support as much as three tons per square foot; if of considerable depth, four tons. Compact gravel and earth, three tons. Compact dry gravel without clay and overlying rock will support as much as six to seven tons; if there is clay between then three tons only. The bearing power of clay alone will vary from one to seven tons or more, according to its nature and its depth below the surface. All soils increase in strength with depth, but, with some, the increase is more than with others. With gravel and sand it is very slight, but with clay it is considerable. The average bearing power of good compact clay not nearer the surface than ten feet is about two tons per square foot, at a depth of 15 to 20 feet, three tons or more; a good stiff blue clay at this depth will carry as much as five tons or more per square foot.

Sand although generally considered entirely useless to build upon if of considerable depth, in a dry state, confined and not likely to be disturbed by water is practically incompressible and will safely support as much as five or six tons per square foot, but, as it is not possible to tell what may happen in the vicinity at some future time to alter the conditions, this class of foundation should be looked upon with suspicion and treated with caution.

Soil and Foundations Often Need Special Treatment

Now a cubic yard of granite weighs approximately two and one-quarter tons; sandstone and limestone, two tons; concrete, one and three-quarter tons; brickwork, one and one-half tons. It is, therefore, obvious that with most structures, the weight upon one square foot of the foundation is greatly in excess of the amount that one square foot of soil can bear, for, with the above values, we see that a wall 27 feet high, built of granite will load the foundation with two and one-quarter tons per square foot; if of brickword, one and one-half tons, and this from the weight of the wall only without considering the structural or other loads carried by the wall, consequently the soil must be strengthened or the foundations designed so that the limit of bearing power is not exceeded, sometimes it is necessary to give both soil and foundation special treatment.

Safe Load Usually One-quarter or One-fifth of the Crushing Power

The safe loads for the various materials used in foundation work are generally taken as one-quarter or one-fifth of the crushing loads. All materials vary considerably in quality, consequently no two varieties of one class will have the same strength; the following, however, can be taken as the safe loads for the respective materials of average quality.

Common brickwork in lime mortar, gauged one to three, three tons per square foot; good pressed brick in cement mortar, gauged one to two, ten tons per square foot; good pressed brick in cement mortar, gauged one to three, eight tons per square foot; lime concrete, gauged one to six, three tons per square foot; Portland cement concrete, gauged one to seven, eight to ten tons per square foot; limestone and sandstone, according to quality, six to twelve tons per square foot.

In considering the class of foundations to be used for any structure there are other factors, in addition to the bearing power of the subsoil, which demand careful consideration. The chief of these are: the comparative cost of materials; convenience of the locality and convenience of access to site. With the last the greatest difficulty occurs with those to be constructed entirely under water; but in whatever position, or under whatever conditions, the principal point to be considered is the prevention of unequal settlement and in some cases side slip or lateral escape of the soil. All structures settle more or less even through the compressibility of mortar joints, but no structural harm will result if the setlement is uniform throughout.

Foundations Should be Incompressible

A good foundation should be as solid and incompressible as possible. If the soil is stratified the pressure caused by the weight of the structure should act at right angles to the strata. If the foundations cannot be designed to admit of this there will be danger of side slip which must be prevented. If the site is inclined the bed of the foundation should be benched out frequently. On inclined sites the strata is sometimes liable to slip under the benches. This can only be prevented by piling along the lower side of the foundation. If a spring is found crossing the site it should be diverted around the building by means of a specially constructed channel or by pipes and carried into its original course below the cite. Catch drains should also be provided for surface water.

Determine the Soundness of the Site

Before designing the foundations of important structures the soundness of the site should be determined. This is generally done by boring with an auger and examining the borings taken from a depth depending upon the weight of the structure to be erected; if the borings show soil of a satisfactory nature the bearing power at the required foundation depth should then be determined. This can be done by excavating pits sufficiently large to enable a bearing plate, preferably two feet square to be placed in position without disturbing the soil upon which it is to rest; this plate should then be gradually loaded and the rate and extent of settlement carefully observed both during loading and at least 24 hours after loading. Upon the result of this test the safe load for the soil can be determined and the foundation designed accordingly. Pot-holes or soft places should be excavated and filled in with gravel or broken stone carefully rammed and made as nearly as possible equal in bearing power to the surrounding soil. If there are any drains, sewers, or other pipes passing through the site that cannot be removed the walls should be arched over them leaving a clear space of several inches between the drain or pipe and the soffit of the arch.

What Constitutes Good Foundations

Solid rock free from clay holes, rotten parts and serious faults or shakes provides a good foundation and only needs levelling for the footings; this, however, generally involves considerable labor resulting in costly work. Beds of rock with partings of clay between them are not to be trusted, being liable to slip, particularly if the beds are inclined.

Gravel, if compact and not liable to escape sideways under pressure, is one of the best soils to build upon. If well graded from fine to coarse it is almost incompressible; is easily levelled and is not affected by exposure.

Sand, if confined so as to prevent lateral escape under pressure in a dry state and not likely to be disturbed by water, is also practically incompressible and will provide a good foundation, but at all times this class of foundation should be looked upon with suspicion and treated with caution.

Clay is, as a rule, reliable from a constructional point, but from its dampness it is an undesirable soil upon which to erect dwelling houses. It is also subject to considerable èxpansion and contraction as the moisture it contains varies with the temperature or with the subsoil drainage. If subjected to the heat of the sun it will shrink and crack. These cracks will become full of water through rain when expansion with great force takes place with probably serious results to the structure. Similar expansion also occurs with the moisture freezing during the winter, consequently, foundations on clay should be carried sufficiently far below the surface to be beyond atmospheric influence.

Portland Cement Concrete Forms an Ideal Foundation

An ideal foundation for a building is a solid bed of Portland cement concrete reinforced with steel rods spread over the whole of the site extending two or three feet beyond the walls, with a thickness depending upon the nature of the ground. The reinforcement increases the transverse strength, also greater strength is obtained with less depth than would be required if plain concrete were used. Many fairly large buildings have been floated, as it were, on made ground not much better than mud in this way and have stood without crack or settlement.

The concrete if not be be reinforced should be composed of Portland cement and broken hard limestone or sandstone, granite or trap rock, brick or gravel, which must be entirely free from clay, organic refuse and other impurities and sufficiently small to pass through a 2½ inch mesh. For ordinary purposes suitable proportions are 5 parts of aggregate, 2 parts of sand and 1 part of cement. The aggregate is best if damp before using but not dripping wet. If it is very rough and porous the proportions of cement and sand should be greater as a good deal is absorbed into the pores of the aggregate. The amount of water required for mixing will also vary with the absorbent nature of the aggregate. Therefore, a definite quantity cannot be specified, but sufficient should be used so that when well mixed the mass will be of a pasty consistency or what is known as a medium wet mixture. On no account should it be so wet as to flow out almost like a liquid. It should require light spreading and tamping to properly fill the forms. At the present time the general tendency is to use a very wet mixture which means an excess of water. This is economical for the cantractor, particularly if the concerte is deposited by chuting, as it flows easily and requires less spreading. There is also a general idea that less or no tamping is required as the mass sets sufficiently dense without it. This idea is not correct. There is a lack of density which is the chief reason why an excess of water should not be used, particularly in reinforced concrete as it results in a more porous concrete of less strength than would be obtained with less water and more tamping.

Neat cement requires 18 per cent. by weight of water to mix it, or about 2 gallons per bushel or 1¼ cubic foot; approximately half only is necessary for the whole bulk of concrete or generally from 20 to 25 gallons per cubic yard.

Correct Mixing of the Concrete is Important

When mixing is done by machine the whole mass should be in continuous motion within the machine for a period of not less than one minute. Machine mixing produces the best results and should be resorted to wherever practicable. If mixed by hand it should be done on a clean and water tight platform, the cement, sand, and aggregate being thoroughly mixed while dry by being turned over two or three times after which the water should be sprinkled on through a hose while the mixture is again turned over at least twice. No concrete which has partly set should be knocked up again for use unless as aggregate.

Depth of Concrete in Foundations

No definite rule for the depth of foundation concrete can be given as this depends upon the nature of the soil and the projection beyond the face of the wall, but it should not be less in depth than 1½ times its projection. It should always be remembered that two feet depth of good concrete is better than four feet of bad, also that the purpose of concrete is to distribute the load uniformly over as large an area as necessary and that excessive depth will not be of value in this respect, but will only increase the load to be borne by the subsoil. Therefore, in bad ground there is nothing to be gained by an unusual depth unless it is carried to a firmer bottom. Where it is necessary for the width of concrete to be considerably more than the thickness of the wall it need not be carried up the full width for the whole height as generally it is as strong or stronger than the material of which the wall is built. It can, therefore, be reduced in width as is seen in Figs. 4 or 5, the slope not exceeding 45 degrees or less with a wet mixture, or boards will be required to keep the concrete in place until it has set. If the bottom of the trench is wet or in a sloppy condition, dry ashes or clinkers, not sand, should be lightly spread over before the concrete is placed. If it is required to place the concrete entirely under water it should be gradually lowered in a bucket with a hinged bottom fastened with a catch on the outside to which is attached a cord and trigger. A cord rammer should also be used. This method can be adopted only in still water.

Designing Piers

When the soil at a conveniently accessible depth is of a satisfactory nature and requires no special treatment to increase its bearing power, it is only necessary to determine the area of soil to be covered by the foundation, so as to permit of a safe and uniform pressure under the whole structure. To determine the dimensions of a pier and its foundations the following steps are necessary:—

(1) Estimate the load to be carried by the pier.

(2) Estimate the approximate weight of the pier.

(3) Determine the sectional area of the pier by dividing the sum of loads 1 and 2 by the safe load for the material of which the pier is to be built.

(4) Add to the load and weight of pier the approximate weight of footing courses, then divide the total load thus found by the safe load for the concrete which will give the spread of the footing courses.

(5) Add to the load used for number 4, the approximate weight of foundation slab, then divide the total load by the safe load for the soil, which will give the area of soil to be covered by the foundation slab.

(6) Compare the above approximate weights of pier and foundation slab with the weights computed from the dimensions obtained, and if the difference is sufficient recalculate the dimensions, using the more accurate weights.

Bank of Hamilton, Winnipeg

Operations are well under way on the foundation work of the new Bank of Hamilton building at the corner of Main Street and McDermott Avenue., Winnipeg. Twenty-eight reinforced concrete caissons were sunk to bed rock beneath the old bank before it was torn down. The Foundation Company, of Montreal and Winnipeg, Mr. J. Q. Rankin, superintendent, are the contractors for building the foundations of the new bank and also for removing the old brick building. The foundations will be sufficiently strong for a ten-storey building, the caissons being 4 feet to 5 feet in diameter. J. D. Atchison, of Winnipeg, is the architect for the new building, which is to cost approximately $400,000.

Strength of Lateral Bonds in Brick Pavements

Mishaps often teach more about the strength of materials than could be learned by years of ordinary use. This fact is demonstrated by an unusual accident to a stretch of brick highway in Wayne County, Ohio. The accident, which occurred this spring, was on one of the newer brick highways and will be worth a portion of the cost of repairing in demonstrating the degree of solidity in lateral bonds that can be had in

A severe test on the strength of lateral bonds in grouted brick pavement.

grouted brick road surfaces when all the details of good construction have been properly complied with.

The accident was a washout on a portion of brick roadway a short distance west of the city of Wooster, the county seat of Wayne, Ohio, where the road skirts a small stream. Following the spring storms, the waters of the creek overflowed the road for some distance for many hours and the swift current gouged away the embankment supporting the road for several hundred feet. For a distance of 60 feet the concrete base of the pavement was undermined and fell away, leaving the brick surface supporting its own weight by its lateral bond only. It is a remarkable fact that the base, a homogeneous layer, should fall away, while the brick course, consisting of a large number of units, should be left undisturbed. More remarkable still was the fact that the brick pavement was able to support a very considerable weight besides its own dead weight, as shown in the figure. The under side of the pavement was bared for 60 feet, with a maximum width of 6 feet, and a good-sized automobile with passengers was able to rest on the edge of the pavement without disturbing it. It was also subjected to a very severe test when boulders for refilling the cut were dumped on it and rolled over the edge. That it stood these tests, argues well for brick pavement. The road will be reconstructed up to the pavement, reversing the customary order of construction.

The Roman Catholic School Commissioners, Montreal, have awarded the contract for a school on Robin Street to Mr. L. Beaudry, at a cost of $136,000 if Queenston stone is used and $3,000 less if Montreal stone is used. Seventeen tenders were received.

Commercial Use of Blast Furnace Slag as a Constructional Material

By E. C. Brown*

BLAST furnace slag has already found its way into an extensive field of industrial usefulness, principally, of course, as construction material. Granulated slag, that is, hard slag ground down to a finer and more granular substance resembling in appearance coarse sand, is used as a material in cement manufacture, as a cushion under brick and block pavements, as a filter material in certain chemical recovery processes, as a fine aggregate in concrete, etc. Hard slag, crushed and screened to size, is used for railroad ballast, for road macadam and paving foundations, as a concrete aggregate, as a filter material in sewage disposal work, as a material in fireproof construction, etc.

Perhaps the most extensive use of commercial hard slag to-day is in road improvement work, in which it has given most satisfactory results. This is so whether in plain water-bound macadam, or in combination with tars, asphalts or other special binders. Several of these roads have been in service from two to five years and are wearing well.

As an aggregate in concrete for all general purposes slag has been thoroughly tested and is far beyond the experimental stages. It has gone into all kinds of buildings, walls, bridge work, light reinforced structures as fence posts and telegraph poles, floors, roof slabs, and in fact into practically everything for which concrete of any kind is suitable. In not a few classes of construction it is especially well adapted because of its relative lightness, good bonding qualities and perfect fire resisting nature.

Physical Properties

Average commercial blast furnace slag has a specific gravity of about 2:62; limestone averages 2:60; granite, 2:68; and trap rock, 2:96. Slag is of a grayish color, breaks with decided angularity, is somewhat porous, and weighs commercially approximately 2,000 lbs. per cubic yard. Of these qualities, perhaps the most important, or at least the most conspicuous, is its porosity, which may be more properly characterized as cellular construction. This accounts for its relative light weight, both in the natural fragment and in combination, as, for instance, in concrete.

At this point perhaps we may as well refer to the weight of some of the forms of blast furnace slag we have been considering:

Crushed and sized bank slag, as ordinarily produced and shipped, weighs 1,900 lbs. to 2,100 lbs. per cubic yard, probably 2,000 lbs. is very near the average.

Granulated slag varies greatly, probably as low as 800 lbs. or 900 lbs. to as high as 1,500 lbs. to 1,600 lbs. average, say, 1,300 lbs.—both fineness and moisture greatly affecting the weight.

It might be interesting to note some of the relations by weight between the slags we have been considering, the raw materials and the metal product. Under average conditions, the weight of slag from the blast furnace is about fifty per cent. of that of the metal produced. This is, however, subject to considerable variation. It may, under certain furnace burdens, be nearly as low as forty per cent. or again, as high as sixty per cent., although that resulting from the production of ferro manganese may even considerably exceed one hundred per cent. Therefore, given the tonnage of iron produced at a plant or in a district, we have at once practically learned the amount (in tons) of blast furnace slag.

The amount of slag to the ton of metal in the steel making or iron refining processes is much less, and also much more variable than that from the blast furnace. It averages rather less than ten per cent. by weight. To roughly complete quantitative analysis, we might add that all the other waste and refuse material would perhaps amount to about twenty per cent. From this we may say roughly, that from a fairly complete modern plant producing, say, one million tons of iron, which it converts into steel, and then rolls into finished or semi-finished products, there is turned out about 800,000 tons of slag and refuse waste material. The metal and this waste are all the solid or non- volatile matter left of the three and a half million tons of raw materials, ore, coke and limestone, used in the original smelting operation.

But little commercial or industrial use has thus far been made of either the open hearth or converter slags as compared with the better known and more abundant blast furnace slag.

Open hearth slag has been ground and used in agriculture with success as a soil corrective, giving higher and quicker results than lime applied in other and more usual forms.

Slag Concrete Tests and Practice

Prior to the year 1908 occasional uses of slag had been made in concrete work, notably machine slag in fireproofing, etc., but during that year there began a series of somewhat elaborate experiments, which involved the manufacture of about eight hundred concrete specimens in the form of 12 in. by 16 in. cylinders, and which continued over a period of two years. These experiments were made for comparative purposes and included specimens of stone and gravel, as well as slag concrete. The tests indicated generally that slag concrete was fully equal to either of the others, and in many instances it proved superior to them.

The results of these experiments were published during the year 1911 in pamphlet form under the title "Furnace Slags in Concrete." The tests had been undertaken at their inception to determine for our own guidance in our construction work, the desirability, or at least admissibility, of slag for concrete purposes. The results seemed sufficiently conclusive to justify the printing of the booklet, not only to furnish information to our own engineers, but also to give some publicity to the facts.

At the present time there is to be undertaken a somewhat more extensive similar series of experiments, in which slags, stones and other materials from rather widely separated sources, are to be tested in concrete.

For several years now at most of our plants we have used slag almost exclusively in our concrete work, and have also sold large quantities for such use. We have yet to learn of a case where unsatisfactory results

*Before the Engineers' Society of Western Pennsylvania.

followed, or any troubles due to the use of the slag developed.

Of all the uses thus far found for blast furnace slag, there is none to which it is so well adapted as its use in concrete. In its texture and physical properties, even in its substance itself, it is so similar to the cement which binds the thousands of particles into a dense and homogeneous mass, that it is almost, if not quite, the ideal material.

A number of things, no doubt, have combined to retard its use; good gravel in abundance, fair stone not too far distant, conservatism of engineers, and sometimes even prejudice against a so-called waste or by-product.

Extension to the Montreal Harbor Commissioners' Elevators

The growing importance of Montreal as a grain port has necessitated from time to time the extension of the elevator accommodation. About 13 years ago the first steel elevator of the Harbor Commissioners was erected; in 1914 an extension to the east and north was completed, and there has just been opened an addition to the west. These additions are constructed of concrete, and each have a capacity of 1½ million bushels, making, with the original capacity of one million bushels, a total of four millions. Besides this, the commissioners constructed in 1911-12 a new elevator, No. 2, of concrete, with a capacity of 2,600,000 bushels.

The extension to the west is, like the earlier one, fire proof, no wood being used. It is 194 x 127 feet, and stands 220 feet above the base of the rails. The foundations consist of over 2,000 reinforced pre-moulded concrete piles, driven. The structure is known as an up-house elevator, the two railroad tracks running through the first storey. The 114 bins, with hopper bottoms, are of reinforced concrete, while the cupola is of structural steel with reinforced concrete floors and roof, the outside covering being of galvanized corrugated steel.

In order to erect the addition it was necessary to remove to another site offices belonging to the Commissioners—the contract being let to the Foundation Company, Limited. It was also found necessary to divert the Elgin Basin sewer.

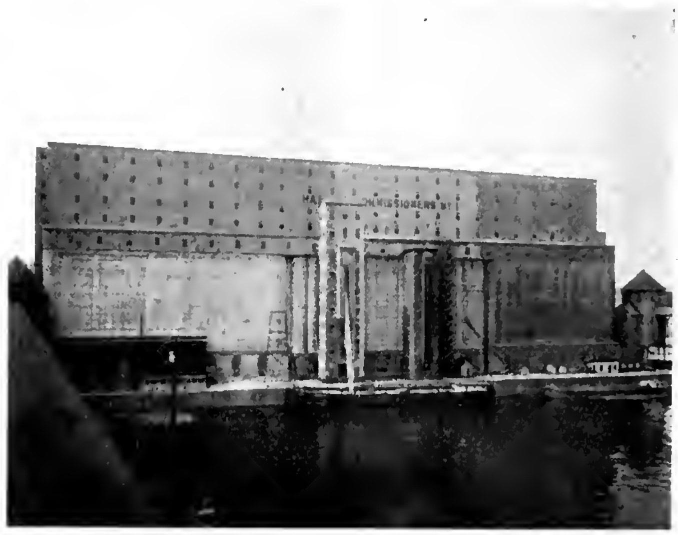
Excavation for the extension was started in March, 1915, pile driving was commenced in May of the same year and completed by the last week of September following. By the 30th of the same month the concrete structure was built as high as the bottom of the bins, and before the end of October the work was up to the top of the bins. This was a very expeditious piece of building. The erection of the steel cupola was started in October and completed in December. During January to May, the equipment was installed, the extension being opened on the 15th of the latter month. Just over 15,000 cubic yards of concrete were poured in two months, and average of 10 cars of stone being received daily during that period. Over 400 tons of reinforcing was utilized.

The grain is received from cars by four steel legs, each of an elevating capacity of 15,000 bushels per hour. The legs receive from the railroad cars running through the first storey. Each leg is provided with a track hopper on each side of the two tracks. These hoppers are so arranged with gates that the grain from either may be elevated as desired. Thus when a carload of grain is being elevated from one side of the leg another car is being unloaded on the opposite side, the gate from the hopper to the leg on the latter being closed. The receiving legs elevate the grain to the top storey, where each leg deposits it into a garner with a capacity of approximately 1,600 bushels. Beneath the garner a 1,600 bushel scale hopper is installed; the receiving scale hopper discharges on to transfer conveyor belts in the cupola, the conveyors leading to the new storage and to the spouts connected with adjacent bins.

The elevator legs are used for shipping grain to the present conveyor system, and grain may be discharged from the shipping bins into the revised arrangement of the shipping conveyor system, by which the shipping belts are carried beneath the new shipping bins, making the entire elevator a homogeneous shipping house.

Four car loading spouts are installed, each receiving from the receiving scales, so that grain may be loaded at one draft. Fourteen of the new bins can be used for sacking purposes.

All the machinery is electrically driven. Electric signals are provided, together with telephones, allowing of rapid communication throughout the entire system. These signals and telephones are also installed in No. 2 elevator and the shipping conveyors.



194 x 127 ft. extension to the elevators of the Montreal Harbor Commission.

The work was carried out for the Montreal Harbor Commissioners. The plans were drawn and the construction supervised by the John S. Metcalf Company, Limited, Montreal, under the direction of Mr. F. W. Cowie, the chief engineer of the Commissioners. The general contract for the superstructure was executed by the Geo. A. Fuller Company, Limited, Montreal, the piling work being done by the P. Lyall & Sons Construction Company, Limited, Montreal. The steel was supplied by the Dominion Bridge Company, and the scales and machinery by Canadian Fairbanks Morse, Limited, Montreal. Mr. P. Lahee was the sub-contractor for the electrical work.

The Union Natural Gas Company of Canada, Chatham, Ont., are constructing forty miles of new ten-inch pipe line to replace a portion of the present eight-inch line to Sarnia. The pipe for this line is being supplied by the Page-Hersey Iron, Tube & Lead Company, of Welland, Ont., and already a considerable portion of the material is on the ground. The actual work of construction will be commenced about the first of June and will be carried through with the company's own organization.

Letters to the Editor

Chicago, May 25th, 1916.

Editor Contract Record:

We were interested to note in your issue of May 3rd, on page 440, a statement relative to the world's highest reinforced concrete tank. It occurs to us that in the interest of your subscribers, and, more particularly, your advertisers, you would use care in your censorship of the articles which appear in your magazine.

The statement of the Blaw Steel Construction Company of Pittsburgh is unfair, and likely to give a decidedly wrong impression of the elevated steel tank which is a product of our manufacture.

The article states that the cost of the steel tower and tank would be less but the life would be short and the repairs, painting, etc., would cause more expense than a concrete tank. As a matter of fact the records of reinforced concrete standpipes show conclusively that while these structures in theory are very excellent things for the storage of water, their actual performance has been very poor, the majority of concrete tanks causing considerable trouble from leakage, and enormous expenditures for maintenance and repairs.

It is not true that the life of the steel tank is relatively short. We have been manufacturing these structures for the past 27 years and so far as we know every one of our tanks are in active service to-day. There is no expense for repairs and the only cost to which the owner may be put is a coat of paint about once in five or six years.

The maintenance of the concrete tank in the way of water-proofing and refinishing of the outside of the structure necessitated by spalling off of concrete is high in comparison to the slight maintenance and cost of the steel tank. Furthermore, in many cases the leakage in concrete tanks has been so serious as to necessitate their complete abandonment. In fact we have built a number of steel tanks to replace concrete structures which have been failures.

We trust that in the interest of your subscribers you will bring out the truth of this matter. In substantiation of our statements we would refer you to the June, 1915, quarterly of the proceedings of the New England Water Works Association.

Yours very truly,
Chicago Bridge & Iron Works,
By F. L. Cook, Sales Engineer.

New Books

Concrete Construction for Rural Communities—by Roy A. Seaton, M.S., Professor of Applied Mechanics and Machine Design and Superintendent of Construction, Kansas State Agricultural College; McGraw-Hill Book Company, Inc., publishers; price $2.00 net. This is a text book treating the essential features of concrete construction in a thorough, yet simple, manner. The author has endeavored to make it suitable for use as a text in a brief course of concrete construction for agricultural or other students in colleges, when accompanied by laboratory exercises and field construction and at the same time has striven to make it valuable to others who have occasion to use concrete. The field covered by the book is illustrated in the following headings: Part 1, Materials, three chapters; Part 2, Plain Concrete, three chapters; Part 3, Reinforced Concrete, two chapters; Part 4, Miscellaneous Matter, four chapters; Part 5, Typical Applications of Concrete, three chapters. Size 5½ x 8 in.; 200 pages; bound in red cloth; well illustrated.

The work of concreting for the Toronto-Hamilton highway was recently commenced in the Port Credit district. Operations are also under way at Burlington.

Obituary

Mr. John Price, who for over forty years has been the proprietor of a large brick manufacturing company in Toronto, bearing his name, died recently at his home in that city. He was 71 years of age. Mr. Price was born in England and came out to Canada as a young man.

The death occurred recently of Mr. David Alexander, of the well-known contracting firm of Alexander & Campbell, at his home at Ottawa. Mr. Alexander started in the contracting business with Mr. Wm. Campbell 15 years ago, and during that time the partners have built up a large business.

Mr. Simpson Fleming, one of Ottawa's oldest and best known citizens, who superintended the erection of the first water mains laid in the capital, died recently at the age of 89 years. He came to Canada from Ireland as a young man and has since lived in the vicinity of Ottawa, where for thirty years he was in the city's employ. For a time he was inspector of installation for the Arnprior waterworks.

Mainly Constructional

East and West—From Coast to Coast

The Milton Pressed Brick Company, Limited, Toronto, have taken out a charter.

The Brotherhood of the Stationary Engineers at Ottawa have been granted a charter.

The Grandview Sheet Metal Works, Limited, has been incorporated with a capital of $10,000, head office at Vancouver.

The new C. P. R. depot at North Toronto is nearing completion. It is expected that the contractors will hand it over to the company in a few days.

A town planning campaign committee has been organized at Halifax, N.S. Mr. Thomas Adams, the town planning expert, was present at the opening and explained the lines upon which he would deem it best to work in that city.

The Port Hope File Manufacturing Company, Limited, has been incorporated with a capital of $40,000; head office, Port Hope, Ont. The company will carry on the business of iron founders and workers and file markers and cutters.

Work on the enlarging of the plant of the Canada Foundries & Forgings Company at Welland has been going on for some time, and it is now announced that operations have been commenced with an increased capacity of 33 per cent.

Building operations in Halifax, N.S., have fallen off somewhat this year. The total number of permits issued during April represented a value of $95,924, as compared with $125,890 in 1915, and the total for the year to date is $141,716, while for the same period last year it was $246,278.

The United States reclamation project ditch across the boundary south of Cardston, Alta., which was recently completed, is reported as now requiring from 15 to 30 miles of cement lining, calling for 500 car loads of cement. The order is to be delivered at Cardston and hauled across the line from that point.

It is reported that a Windsor syndicate is being formed to build a thousand houses to accommodate the surplus population of Detroit which cannot find housing accommodation. The houses will be built in a section of the city for which increased transportation facilities are now being planned by the City Council.

The contract for the buff stone for the new Union

Depot, Toronto, has been awarded to George Oakley of Toronto, at a price of $300,000, representing about fifteen thousand tons of cut stone. This stone will be quarried in Illinois, and in order to avoid duty, sent to Canada in the rough state and worked up here.

The beginning of a broader and more extensive system of road repair and rebuilding is evidenced in North Monaghan, Ont., this spring. A new road drag has recently been put into operation on No. 6 division, in order to facilitate the work. The gravel and crushed stone will be supplied from the big C. P. R. pit in that district.

The Contractors Equipment Company, Limited, has been granted letters patent of incorporation to carry on the business of dealers in contractors' equipment and supplies generally, and also the business of dredging, excavating and steam shovel work of all kinds. The capital of the company is $40,000, and its head office is in Toronto.

For the year ended March 31st last the earnings of P. Lyall & Sons Construction Company, Limited, Montreal, totalled $234,644, an increase of $14,967. After providing for bond interest, sinking fund, and preferred dividend, $32,362 is carried forward. The sum of $376,194 was spent for machinery and buildings for manufacturing munitions.

A meeting of the City Council of Woodstock, Ont., was held recently to decide upon the best type of permanent paving for the streets of the city. A large number of ratepayers were present and the debate occupied a long session. No decision was reached, however, the aldermen considering another tour of inspection necessary before deciding on the question.

At the annual meeting of the National Brick Company of Laprairie, Que., a net deficit of $63,170 was reported for the year ending February 29. The president, however, stated that since March 1 considerable improvement had been noted in the demand for bricks and the company had been able to close contracts so far this spring for about ten million bricks at fair prices.

British Columbia's first steel, ocean-going, cargo steamer will be built at the Wallace Shipyards, North Vancouver, under a contract recently placed by the firm of Dingwall, Cotts & Company, through their Vancouver manager, Mr. John Eadie. The boat will be 315 feet long with 45-foot beam. She will have a carrying capacity of 5,000 tons and a speed of nine and a half knots.

The two most important Montreal building schemes for Montreal this season are for theatres. One is to be built on St. Catherine Street West by the Fleischmann Construction Company, New York, for Marcus Loew, of New York. It will seat 3,750 people. The other is for the United Theatres Limited and Keith interests, the plans for which are being drawn up by Mr. D. J. Spence, architect, Montreal.

The contract the Peter Lyall & Sons Construction Company received in connection with the reconstruction of the Parliament Buildings at Ottawa covers the building of the main walls and certain other work, the total estimate of which is around two million dollars. The company is to be paid 8 per cent. on the actual cost of the operation. For the inside of the buildings, such as the construction of the chambers, plumbing, heating, painting and decoration, competitive bids will be asked.

A scheme is on foot to construct an international highway along the boundary line between the United States and Canada, to be named the "Peace Highway," in celebration of the 100 years without war between the two countries. The question was first taken up by the council of Matsqui, B.C., and the commissioners of Whatcom County, Wash., and it is now proposed to bring it before the Dominion Government and the United States Congress. The Whatcom County commissioners have already outlined a highway from the salt waters of Blaine and White Rock to the mountains near Sumas and Huntingdon, as the first unit of what eventually it is hoped will be a paved highway from the Pacific to the Atlantic along the boundary, connected with the Pacific Highway from Blaine to California and the Interprovincial highway from Vancouver to Chilliwack.

The council of St. John, N.B., recently discussed the question of replacing the old cement pipe, which runs through what is known as the "dry lake," with new water mains to be carried around the lake on dry land, a scheme which will involve the expenditure of some $40,000. Tenders are to be called for piping, cast iron and steel, in order to make a comparison of prices. The trouble with the cement pipe is the difficulty in making repairs owing to the nature of the ground through which it runs.

A meeting of the Council of Saskatchewan Architects was held recently at Regina for the purpose of receiving applications for registration. One of the items of business was the appointment of a new secretary to take the place of Mr. Knight, who resigned, having joined the 195th Battalion. Mr. Lindley H. Bennet, architect for Regina public schools, was appointed to fill the vacancy. Lieut. Thompson resigned as secretary of the examining board and Mr. Cooper, of Saskatoon, is taking his place.

The town of The Pas, Man., is inviting tenders for sewage lift pumps with the necessary motors, for the purpose of pumping raw sewage and surface drainage from a chamber with a bottom elevation at 819 feet. Two single stage vertical submerged type centrifugal pumps with a speed of not more than 680 r.p.m. are required, one capable of delivering 500 Imperial gallons and the other of 1,000 Imperial gallons per minute. The sewerage is discharged into the main sewer and then into the river; during a portion of the year sewage can be discharged by gravity, but other months the water level in the river changes, thus increasing the head of the water over the sewer outlet to such an extent that the gravity discharge ceases, and the lift pumps are then required. The elevation of the pumps will be 827 feet. The two vertical type induction motors are to be 3 phase, 60 cycle, 220 volts, with impregnated winding, and with automatic float type controlling devices. The plans also provide for three 5-kw. single phase, 2200 volt primary 110 and 220 secondary volt, oil-cooled transformers or one 3 phase 15 kw. 220 volt secondary with primary fuse cut outs, hanger irons and oil. Messrs. Murphy and Underwood, Saskatoon, are the consulting engineers.

The Saskatchewan Co-operative Elevator Company propose to erect a terminal elevator at Port Arthur, Sask., to be completed for the harvesting of the 1917 crop. It is to be entirely built on a water site, running out from the shore a distance of about 1,400 feet to the public harbor and having a frontage on the harbor of 500 feet. The piles to be used in the foundation, which will number probably 8,000, owing to favorable conditions will not require to be more than about 25 feet in length. A contract for driving them is to be let shortly. The plant will be of fireproof construction, principally reinforced concrete, and the first unit of storage tanks will have a capacity of two million bushels, while provision has been made for the addition of other units to bring the storage up to eight million bushels at a later date. The workhouse, which will have 106 bins with a capacity of 500,000 bushels, will be of the "rapid handling" type. There will be sixteen receiving pits arranged in rows of four into which thirty-two cars of grain per hour can be unloaded. The consulting engineer whose services the company have secured to design and supervise the construction of the new terminal is Mr. C. D. Howe, who has already established an office at Regina, where a staff is at work preparing drawings and specifications. It is hoped that the contract for the entire work will be signed by September 1 next.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks, Sewerage and Roadways

Edmonton, Alta.
The City Council propose to lay plank sidewalks, at an approximate cost of $25,000. Engineer, A. Haddow.

Lindsay, Ont.
The Town Council contemplate the construction of about 8,200 square yards of asphaltic concrete pavement with curbs, gutters, manholes, etc. Approximate cost, $20,000.

Ste. Cecile de Whitton, Que.
The Municipal Council propose to construct waterworks at an approximate cost of $5,000. No tenders will be called. Secretary, J. G. Beaudoin.

CONTRACTS AWARDED

Assiniboia, Man.
The Rural Municipality have let the contract for construction of watermain to T. Jackson & Sons, 370 Colony Street, Winnipeg, at $3,400, and for sewers to the Hurst Engineering & Construction Company, 406 Ashdown Building, Winnipeg, at $15,834.

Moncton, N.B.
The City Council have awarded the contract for construction of pavement on Main Street to the Warren Bituminous Paving Company of Ontario, Ltd., McKinnon Building, Toronto, at $51,968.

Ottawa, Ont.
The contract for construction of tarvia pavement on Russell Avenue has been let by the City Council to R. A. Morrison, care of the Engineer, F. C. Askwith. Approximate cost, $9,000.

Raleigh Township, Ont.
The Town Council have awarded the contract for drain improvements to J. E. Doyle, Cross Street, Chatham, at $4,000.

Railroads, Bridges and Wharves

St. Lin de Laurentides, Que.
The Roman Catholic School Board have let the general contract for the erec-

tion of a college to Gauthier & Ouellette, care of C. A. Reeves, 709 Power Building, Montreal.

St. Pierre, Que.
The School Board have awarded the contract for the construction of a frame school to Z. Cloutier. Approximate cost, $6,200.

Windsor, Ont.
The general contract for the erection of an addition to the Collegiate Institute has been awarded to Wells & Gray, Limited. Manning House Block. Approximate cost, $150,000.

Business Buildings and Industrial Plants

Brantford, Ont.
Tenders will be received until June 9th for the erection of a factory for the Royal Paper Box Company. Architect, J. Evans, 30 Water Street N., Galt. Approximate cost, $12,000. Brick and concrete construction.

Gananoque, Ont.
F. Delaney contemplates remodelling premises on King Street for an opera house, and is receiving prices on metallic ceilings, hard brick, beaver board, electric fixtures and chairs. Approximate cost, $4,000.

Hamilton, Ont.
The W. T. Rawleigh Company, Freeport, Ill., will receive tenders until June 12th for the erection of a factory. Architects, McPhie, Kelly & Darling, Bank of Hamilton Building. Reinforced concrete construction.

Levis, Que.
Tenders on the construction of a station, viaduct and train shed for the Intercolonial Railway will be received until June 17th by J. W. Pugsley, Secretary Department of Railways and Canals, Ottawa. Plans and specifications at office of the Chief Engineer of the Department, with Chief Engineer, Moncton, N. B., with Resident Engineer, Levis, and the Architects, Ross & McDonald, 1 Belmont Street, Montreal.

London, Ont.
Preliminary plans for the proposed hydro office will be prepared by General Manager Buchanan, and an Architect will be appointed to supervise the architectural features.

Montreal, Que.
J. S. Jacobs and William Bell, Jacobs Building, are about to start work on the erection of a picture theatre on Sherbrooke Street, estimated to cost $50,000. Architect, D. J. Crighton, 282 St. Catherine Street W. Stone, plastic brick and steel construction.

Ottawa, Ont.
Peter Lyall & Sons Construction Company, Limited, are building a workshop on Sussex Street, estimated to cost $35,000. Frame construction.

Peterboro, Ont.
William Langford, Water Street, is preparing plans of a factory for the Bonner-Worth Company, McDonnell and Cambridge Streets. The project is very indefinite at present. Approximate cost, $10,000.

Russell, Man.
The Union Bank of Canada propose to rebuild their premises on Main Street, and have appointed as Architects Jordon & Over, 47 Canada Life Building, Winnipeg. Approximate cost, $8,000.

Saguenay River, Que.
The Du Pont Powder Company, Wilmington, Del., have secured properties and water rights preparatory to the construction of a plant for the manufacture of liquid air. Approximate cost, $10,000,000.

Toronto, Ont.
C. W. Spink, 170 Lake Front, has commenced the erection of a refreshment pavillion, estimated to cost $3,000. Frame construction.

Plans have been drawn for a garage to be built on Mill Street by William Davies & Company, 521 Front Street E. Brick construction. Estimated cost, $3,500.

Plans have been prepared for a warehouse to be built on Cawthra Avenue for the Campbell Flour Mills Company, Limited. Reinforced concrete construction. Estimated cost, $20,000. Engineers, J. H. Fromanhauser Company, Limited, 604 Temple Building.

The Harris Abattoir Company, Ltd., Union Stock Yards, have had plans prepared for an addition to their premises, estimated to cost $50,000. Brick construction.

The Conger Lehigh Coal Company, 95 Bay Street, have commenced the construction of a coal elevator and pockets, estimated to cost $10,000. Frame construction.

Vancouver, B.C.
Tenders on the construction of a railway station at False Creek for the Canadian Northern Railway will be received until noon, June 20th, by the General Manager, M. H. McLeod, Vancouver. Architects, Pratt & Ross, 1011 Electric Railway Chambers, Winnipeg. Approximate cost, $1,000,000.

Weston, Ont.
Prack & Perrine, 808 Lumsden Building, Toronto, are preparing plans of a factory for T. A. Russell, King and Duncan Streets, Toronto. Steel and brick construction. Estimated cost, $150,000.

CONTRACTS AWARDED

Brantford, Ont.
The Ham & Nott Company, Limited, 81 Elgin Street, have commenced the rebuilding of their premises, and have let the roofing to the Brown-Jarvis Roofing Company, 9 George Street. Estimated cost, $3,000.

Halifax, N.S.
The contract for plumbing required in alterations to a theatre for the Academy of Music has been let to G. A. Perrier, 35 Granville Street, and electrical work to Farquhar Brothers, Barrington Street.

Hamilton, Ont.
The general, masonry and carpentry contracts for the erection of an addition to the premises of the Canadian Ste.l & Wire Company have been let to Woodhall & Sinclair, 105 Sanford Avenue S. Approximate cost, $4,000. Mill construction.

The general, masonry, carpentry and roofing contracts for the erection of a store for W. Dyment, 58 St. Mathews Avenue, have been let to Blake & McDonald, 73 Central Avenue. Brick and stone construction. Estimated cost, $3,000.

The contract for plumbing required in an addition to the factory of the T. Eaton Company has been let to Drake Avery Company, John Street.

The general contract for the erection of a factory for the Mercury Mills Ltd., 80 Park Street N., has been let to W. H. Cooper, Clyde Building. Approximate cost, $125,000.

London, Ont.
The following contracts have been let for alterations to the Bank of Montreal:—carpentry, Tambling & Jones, Hamilton Road; painting, Colerick Brothers, 212 Dundas Street; plumbing, Noble & Rich, 237 Queens Avenue; electrical work, Benson & Wilcox, 264 Dundas Street. Approximate cost, $6,000.

Montreal, Que.
The general contract for the erection of an office building for Lymburner Ltd., 515 Commissioners Street, has been let to the Atlas Construction Company, Limited, 37 Belmont Street. Sub-tenders will be called for. Approximate cost, $8,000.

In connection with the addition to the premises of the Canadian Consolidated Rubber Company, the roofing has been let to G. W. Reed, 37 St. Antoine Street. Heating, plumbing and electrical work by owners.

The general contract for the erection of a store and residence for B. Zeolis, 350 City Hall Avenue, has been let to Church Ross Company, 40 Hospital St. Approximate cost, $6,900.

The general contract for the erection of a factory and shed for the Dominion Oil Company, 1192 St. Catherine Street E., has been awarded to Reid, McGregor & Reid, 511 St. Catherine Street E. Approximate cost, $10,000.

New Toronto, Ont.
The contract for steel required in the erection of a factory for the Goodyear Tire & Rubber Company, 152 Simcoe Street, Toronto, has been let to McGregor & McIntyre, 1139 Shaw Street, Toronto.

Ottawa, Ont.
The contract for painting required in the erection of a building for Jackson Booth & Syndicate, Metcalfe Street, has been awarded to G. T. Green, 796 Bank Street, and plastering to Frank Hunt, 115 Arlington Avenue.

The contract for an addition to a restaurant on Queen Street for Sir G. Perley has been let to H. P. Beck, 126 Sparks Street. Brick construction. Approximate cost, $3,000.

Peterboro, Ont.
The contract for heating in connection with additions to the premises of the Bonner-Worth Company has been awarded to George Brenton, Queen and Hunter Streets.

Preston, Ont.
In connection with the additions being built to the factory of the Solid Leather Shoe Company, the contract for

brick work has been awarded to F. Schroeder. Carpentry by general contractor.

Work has been started on the erection of a business block on Argyle Street for F. G. Wurster. The brick work has been let to Wirsching Brothers, and carpentry to Norman Hipel. Approximate cost, $3,000.

St. Catharines, Ont.
In connection with the factory in course of erection for the Dominion Food Company, the contract for roofing has been let to the general contractors, Newman Brothers.

Toronto, Ont.
In connection with the erection of the new Union Station, the cut stone contractors, George Oakley & Son, have let the contract for delivery of stone to the Indiana Quarries Ltd., C. T. Penn, Local Representative. Contract involves about 160,000 cubic feet.

J. D. Young & Son, 835 College Street, are receiving tenders on painting required in the erection of a workshop for A. R. Clarke & Company. Approximate cost of building, $10,000.

The general contract for the erection of an office building on Bay Street for the Trusts & Guarantee Company, Ltd., has been let to William Cowlin & Son of Canada, Ltd., Mail Building, and the plumbing, heating, ventilating and wiring contracts to Bennett & Wright, 78 Queen Street E. Approximate cost, $200,000.

Vancouver, B.C.
The following contracts have been let in connection with the erection of the proposed station at False Creek:—steel, Canadian Northwest Steel Company; lumber, Hanbury & Company, Vancouver Lumber Company, False Creek Lumber Company, and Small & Bucklin; stonework, MacDonald & Wilson; brick, Sidney Island Brick and Tile Company; electrical work, Mundy Rowland Company.

In connection with the addition to the plant of the Begg Motor Company, the contract for roofing and steel metal work has been let to Little & Lee, 682 Seymour Street, and the electrical work to C. H. E. Williams, 509 Richards St. Plastering by day labor.

Windsor, Ont.
Work has been started on the erection of a store and flats for J. Stone, 37 Aylmer Avenue. The general contract has been let to Abbott & Gray, 42 Parent Street. Brick veneer and concrete construction. Approximate cost, $5,500.

A. J. Rattray, Engineer, Stair Building, Toronto, has let the following contracts for the erection of a grand stand: steel, Hepburn & Disher, Van Horne Street, Toronto; concrete, C. W. Cadwell, 261 Ouellett Street; corrugated iron roofing, Windsor Hardware Company, 71 Sandwich Street E.; track building, Orpen Company, Limited, 166 King Street E.; track building, Orpen Company, Ltd., 166 King Street W., Toronto. Approximate cost, $100,000.

Yorkton, Sask.
The contract for masonry required in the erection of a garage for Charles Flik and Mrs. Lindsay has been let to W. Peterson, who may also be awarded the general contract. Brick construction. Approximate cost, $4,000.

Residences

Halifax, N.S.
The Eastern Investment Corporation, Cragg Building, are receiving tenders on heating, plumbing, and electrical work required in connection with residences which they propose to build.

London, Ont.
Watt & Blackwell, Bank of Toronto Building, are preparing plans for an apartment for R. H. McKnight, 296 Queens Avenue. Brich construction. Approximate cost, $10,000.

Plans of a residence are being prepared for A. O. Hunt, 23 Wortley Road, by Watt & Blackwell, Bank of Toronto building. Estimated cost, $4,000. Frame and white brick construction.

London Township, Ont.
Thomas Smibert, R.R. No. 1, Ilderton, Ont., has prepared plans of a residence estimated to cost $3,000, and will let contract shortly. Red pressed brick construction.

Plans of a residence have been prepared by David Leckie, R.R. No. 1, Hyde Park. Red pressed brick consruction. Estimated cost, $3,000.

Montreal, Que.
H. Wilensky, 1900 St. Urbain Street, is considering the erection of six flats at an approximate cost of $5,000, and alterations to a residence estimated to cost $5,000.

H. Brunelle, 122 Prefontaine Street, is having plans prepared for a residence, estimated to cost $5,000. Architects, P. L. W. Dupre & Company, 567 Delorimier Street.

The erection of a residence is contemplated by J. Lecavalier, 74 St. James Street. Approximate cost, $3,000.

John Dominique, 166 Marcil Street, is about to start work on two flats, estimated to cost $6,000. Brick construction.

J. P. Tremblay, 291 Prudhomme Street, is about to commence the erection of two flats, estimated to cost $5,000.

A. Gregoire, 418 Northcliffe Boulevard, is about to start work on the erection of two flats, estimated to cost $4,500.

Niagara Falls, Ont.
John Lamb, 320 Victoria Avenue, has commenced the erection of a residence on Burns Avenue, estimated to cost $1,000. Plumbing, heating and electrical work will be let.

Ernest Scott, Victoria Avenue, has started work on a residence, estimated to cost $4,000, and will let plumbing, heating and electrical work. Brick veneer construction.

A. Smith, Southend Post Office, has commenced the erection of a residence on Roberts Street, and will let plumbing, heating, and electrical work. Approximate cost, $4,000.

The erection of a residence on Cookman Avenue, has been commenced by F. Maland, Cookman Avenue, and A. Smith, Southend Post Office. Heating, plumbing, and electrical work will be let.

Ottawa, Ont.
H. Atkinson, 39 Rosebery Avenue, proposes to build a residence, at an approximate cost of $5,500. Brick veneer construction.

W. F. Mackenzie, 184 Concord Street, is considering the erection of a residence, to cost about $5,000. Brick veneer construction.

The Oakland Land Company have commenced the erection of a residence, and are receiving tenders on masonry, carpentry, roofing, plastering, painting, heating, plumbing, and electrical work. Manager, W. J. Spratt, 307 Sunnyside Avenue. Estimated cost, $5,000.

B. A. Grison, Fentiman Avenue, proposes to build a residence at an approximate cost of $6,000, and has had plans prepared. Tenders are now being received on plastering, painting, heating, plumbing, and electrical work. Stucco construction.

Toronto, Ont.
W. S. Grimshaw, 462 Avenue Road, proposes to build three duplex residences, at an approximate cost of $18,000, and has had plans prepared by P. H. Finney, 79 Adelaide Street E. Brick construction.

Charles Hough, 905 Broadview Avenue, has commenced the erection of a residence, estimated to cost $4,500. Smaller trades will be let. Brick construction.

Moore & Gemmell, 14 Kenwood Street, have commenced the erection of a pair of residences, estimated to cost $4,200, and will let smaller trades. Brick construction.

G. Nicholson, 6 High Park Gardens, has prepared plans of four residences, which he proposes to build on Boston Avenue. Smaller trades will be let. Brick construction. Estimated cost, $4,000.

A. & A. Grant, 837 Logan Avenue, have commenced the erection of a residence on Playter Boulevard, estimated to cost $3,500. Brick construction. Smaller trades will be let.

George Blackmore, 89 Bernard Avenue, contemplates the erection of a residence, estimated to cost $10,000.

S. Garfunkel, 316 Bathurst Street, has commenced alterations and repairs to five residences, estimated to cost $3,000.

J. T. Moore, 30 Brookmount Street, proposes to build a residence and has had plans prepared by P. H. Finney, 79 Adelaide Street E. Smaller trades will be let. Estimated cost, $3,200.

H. C. Long, 605 Traders Bank Building, is considering the erection of eight residences on Keewatin Avenue, at an approximate cost of $5,000 each. Smaller trades will be let. Brick construction.

The International Land Corporation, 43 King Street W., are building four pairs of residences on Craighurst Street. Brick construction. Approximate cost, $16,000.

E. C. Hurlburt, 44 Castlefield Avenue, has commenced the erection of three bungalows on Briar Hill Road, and will let smaller trades. Brick construction. Approximate cost, $3,000 each.

E. C. Hurlburt, 44 Castlefield Avenue, is building two residences, estimated to cost $5,000 each, and three bungalows at an approximate cost of $3,000 each. Brick construction. Smaller trades will be let.

Work is about to start on the erection

Tenders and For Sale Department

Department of the Naval Service

Tenders for Hatchery and Dwelling

Sealed tenders addressed to the undersigned and endorsed "Tender for Hatchery and Dwelling" will be received up to 12 o'clock noon on **Tuesday, June 20**, for the Construction of a

Fish Hatchery and Dwelling at Kingsville, Ont.

Forms of tender, specifications and all necessary information may be obtained by application to the undersigned. Plans and specifications will be exhibited at the office of the District Engineer, Public Works Department, Windsor, and the Postmaster, Kingsville, Ont.

Tenders must be accompanied by an accepted cheque payable to the Honourable the Minister of the Naval Service for One Thousand Dollars ($1,000.00). This will be held for forfeit if the party tendering fails to enter into the contract if called upon to do so, or in any way fails to properly fill same.

G. J. DESBARATS,
Deputy Minister of the Naval Service.

Department of the Naval Service,
Ottawa, May 27, 1916.

Unauthorized publication of this advertisement will not be paid for. 23-24

Canadian Government Railways

TENDERS

Sealed tenders, addressed to J. W. Pugsley, Secretary, Department of Railways & Canals, Ottawa, Ont., and marked on the outside, "Tender for Levis Station," will be received up to and including **Saturday, June 17th, 1916**, for the construction and erection of

Viaduct, Station and Train Shed

at Levis, P. Q.

Plans, specifications and blank form of contract may be seen on and after June 1st, at the office of the Chief Engineer, Department of Railways & Canals, Ottawa, Ont., at the office of the Chief Engineer, Moncton, New Brunswick, at the office of the Resident Engineer, Levis, P. Q., and at the office of Ross & McDonald, Architects, Montreal, P. Q.

Contractors who wish to obtain plans and specifications temporarily for their own use may obtain same from Ross & McDonald on depositing with them a certified bank cheque in favor of the Canadian Government Railways for the sum of $50.00, which will be refunded on the return of the plans and specifications to them.

All the conditions of the specifications and contract form must be complied with.

Tenders must be put in on the blank form of tender which may be obtained from any of the offices at which plans are on exhibition.

A security deposit will be required as called for in tender form.

The lowest or any tender not necessarily accepted.

F. P. GUTELIUS, General Manager,
Canadian Government Railways.

Dated at Moncton, N. B.,
May 29th, 1916. 23-23

Tenders for Motor Tractors and Fire Apparatus

Tenders addressed to the undersigned will be received by registered post only, up to noon on **Tuesday, June 20th, 1916**, for the supplying of the following:

3 Motor Combination Hose and Chemical Engines.

1 Motor Tractor for hook and ladder at Ossington Avenue Fire Hall.

1 Motor Truck for delivering supplies and hauling coal for fire engines.

1 Motor Combination Salvage and Chemical Truck.

1 Motor Hook and Ladder Truck.

Specifications of the above can be seen and forms of tender obtained upon application at the office of the Fire Department, Adelaide Street Fire Hall, Toronto. The usual conditions relative to tendering as prescribed by City By-law must be strictly complied with, or the tender will not be entertained. The lowest or any tender not necessarily accepted.

T. L. CHURCH, Mayor,
Chairman Board of Works.

23-23

Board of Education

Sealed tenders, whole or separate, addressed to the Secretary-Treasurer of the Board of Education, will be received until

Thursday, June 15th, 1916,
for

Exterior Painting, Sundry Schools.

Erection of Flag Poles, Sundry Schools.

Oil Burning Apparatus for Steam Boilers at Earl Grey School.

Self-Feeding, Coal Burning Apparatus for Boilers at Queen Alexandra School.

Plumbing and Drain Work, Sundry Schools.

Sale of Old Houses at 115 and 117 Ryerson Avenue

Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall, Toronto. Each tender must be accompanied with an accepted bank cheque for five per cent. of the amount of tender or its equivalent in cash, applying to said tender only. Sureties for all tenders exceeding four thousand dollars must be furnished by Surety Companies. Tenders must be in the hands of the Secretary-Treasurer, at his office in the City Hall, **not later than 4 o'clock** on the day named, after which no tender will be received. The lowest or any tender will not necessarily be accepted.

MILES VOKES,
Chairman of Property Committee

W. C. WILKINSON,
Secretary-Treasurer.

23-23

Board of Education

Sealed tenders, whole or separate, addressed to the Secretary-Treasurer of the Board of Education, will be received until

Friday, June 16th, 1916
for

Pupils' Special Commercial Desks and Chairs

Teachers' Desks and Chairs

Office Desks, Chairs, Filing Cabinets

Seating for Auditorium, Etc.

for

The New High School of Commerce

Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall, Toronto. Each tender must be accompanied with an accepted bank cheque for five per cent. of the amount of tender or its equivalent in cash, applying to said tender only. Sureties for all tenders exceeding four thousand dollars must be furnished by Surety Companies. Tenders must be in the hands of the Secretary-Treasurer at his office in the City Hall, **not later than 4.30** o'clock on the day named, after which no tender will be received. The lowest or any tender will not necessarily be accepted.

W. W. HODGSON,
Chairman of Advisory Commercial Committee.

W. C. WILKINSON,
Secretary-Treasurer.

23-23

Sealed tenders, addressed to the undersigned, and endorsed "Tender for Riding School, Royal Military College, Kingston, Ont.," will be received at this office until 4 p.m., on **Wednesday, June 14, 1916**, for the work mentioned.

Plans, specification and forms of contract can be seen and forms of tender obtained at the office of Messrs. Power and Son, Architects, Kingston, Ont. Thos. Hastings, Clerk of Works, Postal Station "F," Toronto, Ont., and at this Department.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,

R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, May 30, 1916.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—45139. 23-24

Residences

(Continued from page 49)

of a residence on Oriole Road for R. J. Maclennan, Kent Building. Architect, W. B. Galbraith, 22 St. Leonards Avenue. Brick construction. Estimated cost, $6,000.

G. W. Dale, 12 Butternut Street, is about to start work on a residence, estimated to cost $3,000. Smaller trades will be let. Brick construction.

The erection of a residence at an estimated cost of $7,500, is contemplated by W. P. Levack, 519 Roxton Road. Smaller trades will be let. Brick construction.

Work has been started on the erection of a pair of residences for N. J. Craig, 173 Grace Street. Architect, J. H. Stanford, 17 Westmoreland Avenue. Approximate cost, $5,000.

C. Gardiner, 91 Glenholme Avenue, has commenced the erection of a residence on Northcliffe Boulevard, and will let the smaller trades. Brick construction. Estimated cost, $4,500.

Work has been started on the erection of a residence for J. A. Burns, 66 St Anne's Road. Architect, W. G. Burns, 74 Indian Grove. Approximate cost, $7,000.

Tomkins & Baskerville, 490 Oakwood Avenue, are receiving tenders on plastering, wiring, tinsmithing and installation of hot air furnace in connection with the residence which they are building on Kenwood Street.

J. Stone, 49 Coleman Avenue, is receiving tenders on plastering required in connection with the residences which he is building. Approximate cost, $5,000.

Sarnia Township, Ont.

Adam Storing, Concession 2, has let the general contract for the erection of a residence to John Ellnor, 128 Victoria

Street, Sarnia. Brick veneer construction. Estimated cost, $3,500.

Sault Ste. Marie, Ont.
The contract for plastering required in the erection of a residence for R. T. Lane, 10 Queen Street, has been awarded to W. Wray, 332 Albert Street, and painting to E. T. Grand, Queen Street.

Shawbridge, Que.
The general, masonry, and carpentry contracts for the erection of dormitory cottages for the Boys' Farm & Training School, 115 Mountain Street, Montreal, have been awarded to A. F. Byers & Company, 340 University Street, the terra cotta work to the National Fireproofing Company of Canada, Ltd., 78 Crescent Street, Montreal; steel work to Structural Steel Company, Ltd., 10 Cathcart Street, Monereal; mill work to Lafleur Industriel Incorporee, Ste. Agathe des Monts; heating and plumbing to P. J. Sullivan Company, Ltd., 326 Lagauchetiere Street W. Approximate cost, $25,000.

Smith's Falls, Ont.
The general contract for the erection of a residence for A. Leacock has been let to Fred Scott. Brick construction. Approximate cost, $3,000.

St. Catharines, Ont.
The contract for masonry required in the erection of a residence for A. Robinson, 6 College Street, has been let to Rymer Brothers, Nelson Street. Tapestry brick and stucco construction. Estimated cost, $8,000.

Toronto, Ont.
S. B. Green, 111 Evelyn Crescent, is about to build a residence for A. E. King, 35 Oakmount Road. Brick construction. Estimated cost, $4,200.

In connection with the residence in course of erection for R. D. Kilgour, 45 Willcocks Street, the masonry contract has been let to J. Aldridge, 128 Westmount Avenue. Carpentry by day labor.

Tomkins & Baskerville, 490 Ooakwood Avenue, have been awarded the general contract for the erection of a residence at 498 Rushton Road, and are now receiving tenders on plastering, wiring, tinsmithing, and hot air furnace. Estimated cost, $3,000.

The following contracts have been awarded for the erection of a residence on Warren Road for F. Cameron, c/o. F. S. Baker, Architect, Traders Bank Building: masonry, Gordon Brothers, 1 Delisle Avenue; carpentry, Walker & Robertson, 438 Delaware Avenue; plastering, Taylor & Nesbitt, 18 Havelock Street; roofing, G. Duthie & Sons, Ltd., 80 Widmer Street; painting, Cornelius & Company, 50 Walker Avenue; plumbing, heating, and wiring, Bennett & Wright, 78 Queen Street E.; steel work, McGregor & McIntyre, 1139 Shaw Street. Approximate cost, $15,000.

Westmount, Que.
In connection with the residence in course of erection for T. A. Hubley, 48 Windsor Avenue, the roofing has been let to Campbell, Gilday Company, Ltd., 793 St. Paul Street W., Montreal, and the electrical work to McDonald & Willson Company, Ltd., 99 Drummond Street, Montreal.

The roofing required in connection with the residences now being built for Harding & Heward, has been let to Campbell, Gilday Company, Ltd., 793 St. Paul Street W., Montreal, and the electrical work to McDonald & Willson Company, Ltd., 99 Drummond Street, Montreal.

In connection with the residences now being built by Charles Fyfe, 176 Mance Street, Montreal, the roofing has been awarded to J. Dunphy, 55 Barrie Street; plastering to F. A. Sims, 358 Madison Avenue; painting to H. W. Birtwhistle, 19 Clifton Street, and electrical work to J. B. Staton, 5410 Sherbrooke Street.

In connection with the residence now being built for the Roman Cathodic Commissioners of St. Leo, 360 Clark Avenue, the contract for steel work has been let to the Dominion Bridge Company, Ltd., Lachine; roofing to Duchamme Blais & Company, 1995 St. James Street; plastering to Z. Bouchard, 12 Bouget Street; painting to H. Gauthier, 396 Amherst Street, and electrical work to L. Ortiz, 376 Fabre Street.

Power Plants, Electricity and Telephones

London, Ont.
The Utilities Board will receive tenders until June 14th on the supply of three 200 k.v.a. hydro transformers. General Manager, E. V. Buchanan.

Sackatchewan Province.
The following Rural Telephone Companies have been empowered to borrow money for the construction of their proposed systems: Battlevale R. T. Company, $3,800. Secretary, J. A. Morrison, Waseca; Graham-Chatsworth R. T. Company, $2,500, Victor Rooke, Picnic; Longlaketon R. T. Company, $3,200, Herbert Fisher, Silton.

Warwick Township, Ont.
The Township Council propose to secure estimates on the installation of a hydro system. Clerk, Nathaniel Herbert, Watford, Ont.

Fires

Montreal, Que.
Factory of the St. Lawrence Wagon Company, Ltd., 34 King Street. Loss, $5,00. Repairs will be made.

Vancouver, B.C.
Fish plant and grain elevator owned by the New England Fish Company and Alberta Pacific Grain Company, Ltd. Loss, about $600,000.

York Mills, Ont.
Cottages, stables, garage and poultry buildings owned by F. B. Robins, 86 Glen Road, Toronto. Total loss, $30,000.

Miscellaneous

Toronto, Ont.
The Board of Control will receive tenders until June 20th for the supply of motor fire apparatus. Specifications at office of Fire Department, Adelaide Street W.

Late News Items

Esquimalt, B.C.
The Municipal Council have awarded a contract for construction of sewers to Warren & Stancombe. Estimated cost, exclusive of pipe, $8,000.

Halifax, N.S.
The School Board have let the general contract for the erection of a school on Young Street to Falconer & MacDonald, St. Paul Building, the painting to Walsh Brothers, Metropole Building, heating and plumbing to Farquhar Brothers, Barrington Street, and electrical work to J. Starr & Sons, Granville St. Approximate cost, $75,000.

Hamilton, Ont.
F. F. Dalley & Company, Hughson Street N., propose to build a factory on Burlington Street, at an approximate cost of $100,000, and work will start very shortly.

London, Ont.
William Jeffrey, 419 Simcoe Street, has been awarded the general contract for the erection of a residence for W. I. Spettigue, 261 Hill Street, and has started work. Estimated cost, $10,000.

Medicine Hat, Alta.
The sub-contract for the erection of a flour mill and elevators for the Lake of the Woods Milling Company has been let to the Fegle Engineering & Construction Company, 209 North Archibald Street, Fort William. Brick and concrete construction. Approximate cost, $200,000.

Quebec, Que.
E. A. Tremblay, 69 St. Nazaire St., has commenced the erection of a residence, estimated to cost $18,000. Brick and concrete construction.

Saguenay River, Que.
The report previously issued under this head with regard to the Dupont Powder Company is incorrect. The Company are not planning any construction work.

Sarnia, Ont.
The Board of Education have awarded the general contract for the erection of a school on Lochiel Street to Schultz Brothers & Company, Brantford. Smaller trades will be sub-let. Terra cotta, steel and stone construction. Approximate cost, $55,000.

Toronto, Ont.
W. S. Grimshaw, 462 Avenue Road, has commenced the erection of three duplex residences, estimated to cost $18,000. Smaller trades will be let. Architect, P. H. Finney, 79 Adelaide St. E.

Commissioner of Works R. C. Harris has recommended the construction of asphalt paving on eight streets, estimated to cost $59,300, and concrete sidewalks, estimated to cost $17,000.

William Cowlin & Son of Canada, Limited, Mail Building, who have the general contract for the proposed office building for the Trusts & Guarantee Company, desire to receive sub-tenders on all trades except plumbing, heating, ventilating and wiring.

Westmount, Que.
The general contract for the erection of a residence for J. F. Slessor, 4825 Western Avenue, has been let to Anglins Limited, 65 Victoria Street, Montreal. Terra cotta and brick construction. Approximate cost, $9,300.

Anglins Limited have also been awarded the general contract for the erection of three residences for Warden, Cook & Davidson. Brick and terra cotta construction. Approximate cost, $19,500.

Canadian Stone a Product of Quality Specially Suitable for Our Public Buildings

IT very often happens that the chief difference between two articles on the market, fulfilling similar purposes, and one of which meets the popular fancy while the other does not, lies in the relative amount of advertising these two articles have received. Indeed, it not infrequently happens that a product of decided superiority fails to catch the public fancy because it is exploited by a company whose reputation is not yet established, or who for some reason or other are not able to bring the necessary publicity to bear on the situation to arouse the public interest. In spite of our boasted individualities we are a good deal given to following our neighbor's lead and people, in general, buy what is being bought.

It is not entirely evident that some such reason as this is not responsible for the somewhat limited use of stone as a Canadian building material in the past and, as the business develops, for the increase in our import trade. It catches the popular fancy to go as far afield as possible for their requirements. Of course it cannot be claimed that there are not good arguments being advanced, and doubtless with reason, favoring the use of stone other than Canadian. What actually does seem to be a fact, though, is that Canadians have conceded these arguments without attempting to combat them with others favoring our home stone. We have lain down, in a sense.

* * *

Now, there are always at least two talking points for a salesman—price and quality. In the stone business, however, only the first appears to have been recognized. It seems to have been tacitly conceded that stone is stone and that ends it—that the quality of all stone is the same. Yet one has only to make a tour of the stone buildings in any locality to satisfy oneself that the lasting qualities of different varieties of stone are very different. Some crumble quickly, others discolor, and so on. On the basis of "quality" Canadian stone has never been assailed. It apparently maintains its appearance and its physical characteristics indefinitely.

This being the case the matter of cost ought surely to take second place, especially when this difference is, at best, only a matter of a few per cent. "Value for money received," then, would appear to be a much better talking point—and an entirely proper one—than "cost" alone.

* * *

Also there is another important feature in the use of foreign stone for Canadian buildings—the question of empire loyalty. It so happens that a very large percentage of our public buildings—schools, churches, municipal halls, etc.—are built of stone and, quite frequently, not Canadian stone. Could we not point to these permanent landmarks of our prosperity with greater pride if they were also illustrations of our own natural resources? Would not the use of purely Canadian building materials tend to engender in our youth a confidence in their home land and a more intense spirit of loyalty as a result of that confidence? What matters a few dollars in extra cost if the extra value, and much more, is there? We do not rake the foreign fields for teachers or municipal officers in the hope that we may get something cheaper. We do not bring children from foreign countries to fill the schools because our own children are not suitable. Why then should our public buildings, of all places, be robbed of the prestige of an individuality that would stamp them as "quality" and "Canadian"?

* * *

The present issue of The Contract Record is given over almost entirely to an illustrated description of Canadian quarries and quarry methods. We cannot claim to have covered the subject fully, for the field is as wide as the Dominion. It is confidently hoped, however, that the issue will serve the useful purpose of bringing this phase of our natural resources more insistently before the attention of Canadian engineers, architects, contractors and various municipal bodies. These men have it largely in their power to popularize our home quarries. On their attitude and their ideas of utilizing home resources will hinge in no small measure the immediate future of the Canadian quarry.

How Canadian Quarries Are Meeting Foreign Competition

HOW owners of Canadian quarries and cut stone firms have been able, by means of a duty, to meet the competition of Indiana limestone, is related in the following interview by a representative of The Contract Record and Engineering Review with Mr. John Quinlan, of John Quinlan & Co. and the Quinlan Cut Stone, Limited, Westmount, P.Q. Mr. Quinlan, who is president of the Montreal Builders' Exchange, also makes reference to the cut stone industry as it affects Montreal. He speaks with an intimate knowledge of the subject, having been in business for many years.

"Before the advent of United States stone and machinery," Mr. Quinlan stated, "we used the top portion of the quarry for rubble foundation work, the grey limestone, found at a depth of about 20 feet under the upper layers, being utilized for building purposes in Montreal. The Imperial Bank and the Windsor Hotel are examples of Montreal stone thus employed. The method of quarrying was largely by powder and hand drills. At the time that stone cutters did all the work by hand, powder answered the purpose fairly well, in view of the fact that very little value was placed on the material and workmen's wages were comparatively low. Of course, this method of quarrying would be useless in preparing stone to be cut by gang saws and planers.

"The most important change in the industry was caused partly by the use of concrete for foundations, which took the place of the rubble foundations, and therefore killed the market for the top portions of the quarries. The large advance in cutters' wages was also an important factor in the change. While it was possibly economical to blow out the stone and use the hammer to square up the smaller pieces of stone to hand to the stone cutters to finish the product ready for erection in the building, when wages were at the rate of 20c. to 30c. an hour, the situation was entirely altered when stone cutters were asking 50c. an hour. Besides these elements in the situation, there was the development of the soft stone quarries of the United States, where the monolithic quarries were worked with the channelling machine instead of by powder, the stone being also cut by gang and diamond saws and planers.

"At first the United States stone was imported in the rough, to be manufactured by a few Canadian firms who installed cut stone machinery in order to furnish the market with at least a home manufactured product. This meant, of course, that there was practically no demand for Canadian stone. At the same time our Canadian manufacturers believed that if our quarries were opened upon lines similar to those in the United States, that eventually it might be possible to produce good Canadian stone at a lesser price than it was being manufactured for at that time, but the market was already captured by the American article in so far as the raw material was concerned, and was being fast captured for the finished product. As a matter of fact, the majority of our large buildings erected during 1911-13 were built of American stone cut and finished in the United States.

"The Canadian Government—at our request—investigated the question and found there was absolutely no protection for our quarrymen and manufacturers, for the reason that the small duty levied was more than offset by the reduction in freight on the finished article. In order to encourage the manufacturer and the production of stone, the Government in 1914 imposed a duty on foreign stone, fully manufactured, coming into Canada sufficient to protect the home industry. Shortly after the duty came into force the war broke out, greatly reducing the amount of building here, but Canadian quarrymen and manufacturers, owing to the tariff, are able to supply, and are now manufacturing, all the cut stone that is being used in the Dominion. We are thus in a position to keep our plants going to a limited extent. We are also taking advantage of the dull times to develop our quarries and to install the newest machinery.

"Personally, I hope before the war is over to market Canadian limestone in every way equal to any that has been imported, and at such prices that it will be advantageous to the Canadian consumer to use it. The old buildings in Montreal are examples of our local limestone. It has, for many purposes, excellent qualities, and I hope that its use will be more frequently specified by our architects."

Steel of Special Quality Required for Rock Drills—Subject to Unusual Strains

ROCK drilling in quarries is now prosecuted almost entirely by machine drills. They have a great advantage over the human power plant, because the lost motions and wasted energy in the latter are not only fatiguing, but discouraging. It is the question of results which makes the average laborer's work efficient or inefficient.

The development of hammer-drill machines during the past decade has brought with it high requirements for the drill steel. The steel generally used for rock drilling is a carbon steel and its hardness is dependent upon the percentage of carbon contained. Experience has proven that the proper percentage of carbon is governed chiefly by the hardness of the rock to be drilled and the power of the machine. A bit will not stand the impact if too hard a steel is used on hard ground.

In some drilling practice, as for instance, when hand-feed drills are used, bending stresses are likely to be put on the steel. Additional tensile and compressive stresses are thus induced during the period of the blow, producing an excessive strain in the steel. In such practice a heavy size of steel is to be recommended. Abrupt changes in section and sharp corners should be avoided in drills.

To obtain the finest grain, bits should be forged continuously from the highest temperature employed down to the finishing temperature, which probably is slightly above the point of recalescence. It is advantageous in hardening not to treat it to any higher temperature than necessary. The steel is liable, if heated too highly, to change into a coarse crystallization and develop hardening cracks that may cause ruptures. The shank should also be properly tempered after being hardened.

Shanks often rupture longitudinally, due to careless straightening after the steel has been upset, blemishes in the steel, and groove marks where numerals or other marks have been stamped. The structure of steel used in bits subject to vibrations is of the greatest importance. The car bit structure has been found to stand up best. It is obtained either by cooling the steel quickly through the so-called critical range, without actual quenching, or by rapid cooling and then reheating to about 600 degs. C.

The Merits of Canadian Stone—A Candid Opinion Covering the Fact Fairly

THE Superintendent of Buildings of the Board of Education of one of our largest Canadian cities, who was recently in search of information regarding the merits of Canadian stone, wrote to the management of one of our largest quarries for a candid opinion on the relative characteristics of the various stones that from time to time had come into competition for the school buildings in that city. The following reply was received from the president of the company, and appears to us to state the case for Canadian stone very clearly and fairly:

The following stones are, you are no doubt aware, some of the finest and most durable that can be found anywhere, and, although in some cases there has been a difficulty in obtaining a large shipment, still, that could be remedied if the quarrymen had encouragement given them by the public bodies specifying their use.

Credit Valley

This is a sandstone of uniform color, mostly gray, fairly soft when quarried, hardening with age. Can be cut at reasonable cost on plain work, but, on account of its hardening quality, is slightly higher in price on any ornamental or highly detailed work. The cost of this stone, f.o.b. cars your city, is 55 cents per cubic foot, in rough quarry blocks.

Wallace Sandstone

This is of the same texture as the above, of an olive color, and the cost is seventy cents per cubic foot in rough quarry blocks.

Miramichi

A sandstone of olive color, somewhat softer than either of the above to work and the cost is seventy cents per cubic foot in rough quarry blocks.

Sackville Freestone

A rich brown in color; soft in texture, and therefore easily worked for little, if any, more than the Indiana, U.S.A., stone. The cost is eighty cents per cubic foot f.o.b. your city, in rough quarry blocks.

Queenston Limestone

Blue-gray in color, with a small percentage of buff. Is not unlike Bedford Indiana in appearance, but is unlike that stone in that it is not porous and therefore will not discolor or stain. Is harder and therefore a little more costly to work in ornamental or fine detail work, but, in plain work, can be worked as freely as Indiana. The cost is fifty cents per cubic foot f.o.b. your city, in rough quarry blocks.

Tyndall Limestone

Comes from Manitoba, and on account of the excessive freight, has, so far, not been used very much in the East. I understand, however, that the railways are considering a lower freight rate, which will make it more reasonable. It is similar to Indiana in texture but has a mottled effect in blue and buff colors. A good sample of this stone can be seen in the new C. P. R. station at North Toronto, now nearing completion.

These stones are all of Canadian production, and when you compare the prices with the Bedford Indiana at sixty-four cents per cubic foot, and the Cleveland Sandstone, Gray Canyon, at sixty-five cents per cubic foot, and Buff, at one dollar and ten cents per cubic foot, all f.o.b. your city, the differences are so very small that, obviously, the extra cost of using Canadian stone is in the cutting, and that is of necessity by the wording of your specification, "to be done in the city." Therefore, by using Canadian stone, you not only encourage Canadian industries, but you provide more work for the citizens of your city (who are the ratepayers who provide the money for these works) at, I venture to say, very small extra cost. If your department would specify more Canadian stone, I am sure there is plenty of capital ready to be put into developing this industry, thus assuring an adequate supply.

For your further information I would say that the duty on rough blocks entering this country is about seven cents per cubic foot, and on stone planed, turned and sawn four sides, that is, practically cut ready to set, the duty was formerly forty-five cents per cwt. This is equivalent to about sixty-five cents per cubic foot, to which must now be added 7½ per cent. clear face.

These facts, I think, are sufficient to show you that, at a not too large extra cost, Canadian stone could be used for all purposes in your school buildings, and in the case of plain work, such as bases, etc., they could be used at the same cost, and give work not only to local workmen, but, in its entirety, to Canadian workmen.

The Canadian Stone Business

By C. Cecil Howlett*

THE question, What is the matter with the Stone Business? is one that must present itself with unmistakable emphasis to the owners and operators of quarries at this time. The answer, in the opinion of the writer, is lack of concerted effort on the part of those interested in the industry to check or correct abuses as they occur. At a time when the country is just emerging from a long period of depression, the stone business has not yet felt the livening influence. This dullness, however, seems to affect only our native stone. Foreign stone apparently finds a ready market in our cities.

The following appear to be the principal causes productive of this state of affairs, all of which are capable of being materially reduced in their effect, or entirely removed, by organized effort on the part of the various stone producing interests in the country:—

The lukewarmness of our architects generally, who seem to have drifted into the habit of overlooking our native building stones, but are thoroughly familiar with the merits of the various foreign products which are cutting so seriously into the market. The remedy for this would appear to be a general advertising plan, showing forth the particular merits of the various building stones of this country and directed chiefly to the attention of the architectural profession. It cannot be believed but that if this profession understood the injury being done to a great Canadian industry they would do all in their power to remedy the matter. If, in specifications, the name of the foreign country from which the building material is to be obtained, were given, instead of the particular name of the material, or if the name of the country were named in connection with the name of the material,

* Manager Longford Quarry Co., Longford Mills, Ont.

it would be quickly brought to the attention of the deciding parties that they were, probably inadvertently, discriminating against a Canadian product.

Then there is the freight question and the car supply. These are matters in which the various quarry companies are absolutely at the mercy of the transportation companies. The freight cost of a car of stone in almost all cases, is greater than the value of the material. The idea on the part of the carrying companies seems to be to take toll of all the traffic will stand. The matter of securing cars for shipments is also a very serious one and has a tendency to influence contractors to buy building material of foreign origin, stocks of which are ready to hand in most centres, or use concrete.

Organization of the various concerns interested in the stone business would certainly go a long way towards keeping the merits of stone as a building material of the first class before the constructing community. This latter is badly needed. An intelligent educational campaign keeping the proper place of the various building materials well before those interested would be a great benefit to the general community as well as to the interests involved. The harm where a mistake is made in the choice of a material reacts to the disadvantage of the material employed.

There is a great future before all those industries dealing with construction in this country. As the population increases and our natural resources are further developed there will be an ever greater need for housing our people and products, and with the natural increase in wealth our buildings will become more and more an index of the general prosperity.

Developments in the Quarrying Business

War conditions and the high prices paid for unskilled labor in munition factories, have put most of the quarries in a bad way for labor. The subject of new and improved equipment is being given the fullest consideration by quarrymen who recognize that the shortage of quarry labor is a condition that can be met in no other way. Mechanisms are being produced that are enormously economizing the production of building and crushed stone.

Auto Trucks—Road material, always the heaviest portion of the tonnage going out from the crusher, is in big demand at the present season. The transportation proposition is ever present, and just now, with the shortage of labor and the acute pressure of railroad cars, the auto-truck with trailers added seems to be the only economical solution. As a result, autotrucks have become practically an indispensable part of the road contractors' equipment. The transportation end of road making is always the most important, because it has all to do with the profit that is made by the road contractor.

Fluxing Stone—With steel mills of every class running at full capacity to meet the unprecedented demand for steel and iron, a maximum volume of fluxing stone for furnace operations is required. Quarries producing fluxing stone are likely to have, during 1916, the greatest demand ever known for this particular type of product.

Requisite Features of Stones

Structural stone is employed for so many diverse purposes that the characteristics which make a stone desirable necessarily vary with the nature of the structure to be erected. For building piers for railway bridges, strength and durability are far more important requisites than uniformity of color. While for interior decoration, less durability is necessary, although such stone is expected to exhibit greater beauty and a superior durability to fine chiselling.

The main requisites for a stone are: (1) strength —crushing strength, transverse strength, and elasticity; (2) color; (3) durability; (4) low cost of cutting.

The ordinary physical tests which are commonly applied to building stones to determine its adaptability are: specific gravity, weight per cu. ft.; per cent. of pore space; ratio of absorption; coefficient of saturation; crushing strength; transverse strength; shearing strength; corrosion loss; drilling factor; chiselling factor.

Market Conditions in Hydrated Lime

There are three plants in Ontario manufacturing hydrated lime, located at Guelph, Elora, and Orangeville, respectively. Other producers in Canada are located at Joliette and Hull, Que., and Winnipeg, Man. There has been in the past a large amount of hydrated lime imported into Canada annually from the United States for use as finishing plaster. Canadian plants are able to produce a considerable tonnage, but have not been prepared to take care of the unexpected increase in demand this spring, resulting from the increase in price of the United States products and the increase in duty caused by the recent action of the Canadian Customs in placing hydrated lime in the same class as wall plaster and Portland cement. Canadian firms expect, however, to be in a position shortly to take care of all the business offering, but are handicapped just at present by the high prices and scarcity of labor and slow delivery on orders for machinery and supplies, which are the same difficulties that obtain in all other classes of manufacturing in Canada to-day.

Right Time to Quarry

The best time for quarrying is during the summer, but freshly quarried material should not be allowed to lie in the sun and dry too quickly, as it is liable to become shaky. Stone quarried during the winter, or during very wet seasons, is liable, according to some authorities, to have much lower tenacity when dried, and to remain particularly susceptible to the effects of moisture. A stone is also liable to disintegration if built immediately into a wall without seasoning. Stones for carved work should be worked up as soon as they are quarried and while in the green state, as, when the water is once lost, no amount of wetting will restore them to the original workable condition.

Quarry Drainage

The question of drainage is extremely important in locating a quarry; given the same market, it is impossible for a wet quarry to compete with a dry one, as the additional expense of keeping the excavation free of water may compel the cessation of operations. Where possible, therefore, a quarry should be located where natural drainage is presented. If such a place cannot be found on the property, the operator must reckon with the cost of pumping, and he should assure himself that his competitors are not more favorably situated in this respect.

Geological Features of Canadian Rocks

A Brief Account of the Historical Formations Which Form the Basis of Our Splendid and Varied Quarries.

THE following brief account of the geology of the rocks of Canada, so far as known, is given with the object of indicating the extent and manner of formation of the rocks which are employed as building stone. The most ancient rocks that compose the crust of the earth consist of a series of gneisses, granites, and other crystalline rocks, intermingled with sedimentary materials which have likewise become crystalline through metamorphic agencies.

Pre-Cambrian

This crystalline complex forms the axis or backbone of all the continents, and on its flanks have been deposited the sedimentary rocks which have greatly increased the original extent of the continents. This ancient series is usually referred to as the "Pre-Cambrian." It is also known as the "Azoic," in reference to the fact that no life is known to have existed on the globe during the vast period of time during which these rocks were formed.

Palaeozoic Period

Following the Pre-Cambrian came a long period of many millions of years during which the oceanic waters successively invaded and retreated over certain areas. During this age, which is known as the "Palaeozoic" on account of the fact that a very ancient and extinct type of life existed, the flanks of the old Pre-Cambrian axis were gradually covered with a series of sedimentary rocks. It is apparent that many changes must have occurred during the Palaeozoic era, and that these changes have left evidence whereby the rocks may be divided into systems, and these systems further subdivided into formations. From the oldest to the youngest, the systems of the Palaeozoic are as follows: Cambrian, Ordovician, Silurian, Devonian, and Carboniferous.

During "Cambrian" time the ancient ocean advanced on the Pre-Cambrian axis and its waves beat into sand the fragments of the old rocks which they encountered. In consequence, a fringe of sandstone marked the strand line of the advancing sea, while in the deeper water was deposited the finer material, which consisted chiefly of suspended particles of clay. Cambrian rocks are marked off from the earlier series by the presence of fossils. In some cases numerous fossils are found, indicating beyond doubt the age of sediments; in most cases, however, the intense metamorphism has destroyed the remains of any organism that may have existed. In consequence of these changes, much doubt exists as to the proper age of the rocks of many large areas.

Sackville Sandstone Quarry, Sackville, N.S.

The series of deposits following the Cambrian are classed under the term, "Cambro-Silurian." The rocks of this age are chiefly sandstones, limestones, and shales, usually showing strong metamorphism with the conversion of the sandstones into quartzite, the shales into slate, and the limestone into crystalline limestone. The formation has been invaded by great masses of granite and other eruptives whereby its extent is materially reduced. A period of extensive land elevation and deformation, accompanied by the extrusion of great masses of igneous rocks, marked the close of the "Cambro-Silurian" time.

Following the Cambro-Silurian are the deposits of "Silurian" time, which show less extensive metamorphism although they are invaded by eruptives of a still later age. The rocks consist chiefly of calcareous shales and limestones.

Devonian rocks follow the Silurian; they consist chiefly of shales and limestones with sandstones and conglomerates. Towards the close of the Devonian, extensive earth movements again affected the region. The rocks show evidence of uplifting, with much folding and faulting, accompanied by the injection of enormous masses of granite and other igneous rocks.

Following the "Devonian" came the "Carboniferous" age, which represents a great series of sediments deposited in a sea that gradually encroached on a lowering land surface. The rocks of the Carboniferous proper are divided into three series—lower Carboniferous, middle Carboniferous, and upper or Permo Carboniferous. During the "Carboniferous" time, tilting and disturbance of the strata occurred, so that in some places the different members of the series are already marked off from one another by strong unconformities. The close of the "Carboniferous" age was marked by a wide-spread elevation of the land, which in some places has not been followed by depression.

Mesozoic Period

The only rocks of later date than the Permian belong to the lowest division of the "Mesozoic" age, and are thought to represent estuarine deposits. They consist of red sandstone and shales, which are overlaid by heavy masses of trap.

Ice Age

At a comparatively recent date in geological history occurred the remarkable event known as the "Ice Age," during which the whole of Canada was swept by enormous glaciers, which did much to modify the topography of the country. In their resistless march from the north these glaciers bore immense quantities of boulders of the crystalline, Pre-Cambrian rocks far southward. With the coming of warmer climate and the consequent retreat of the ice, these boulders were left in great numbers over the face of the country.

Dimension Quarrying by the Ancients

Incredible Accomplishments that Stagger the Minds of Modern Builders—Methods of Operation Almost Complete Mystery—A Few Interesting Figures

MERE magnitude alone makes appeal to mankind. Almost every one is interested in the great things of their kind, no matter what they may be. In every age there has been the effort to surpass previous achievements. The Egyptians as a nation are chiefly notable for their grandiose work, and the result is that the pyramids, the Sphinx, and various giant obelisks and monster temples stand as their principal monuments. The Egyptians worked in stone, as does every nation that wishes to leave imperishable records of their civilization. The natural tendency of this people was helped by the fact that close at hand were inexhaustible deposits of high-grade stones, limestones, sandstones, quartzites, granites, syenites, basalts, and porphyries. The manner in which the Egyptians quarried these stones in huge monolithic masses, transported them for immense distances, and erected them into stately piles of masonry, is one of the marvels of history. Some of their work was of almost inconceivable magnitude. The two Colossi of Memnon at Thebes, are carved of a pebbly and quartzoze sandstone conglomerate of a yellowish brown color and very difficult to work. The height of the statues alone is 52 ft., and of the pedestals 13 ft. They represent Amenophis III., who erected them in 1427-1392 B.C. The northern one was the famous vocal statue of Memnon, which was reputed to give out a song as the rays of the morning sun smote it.

One striking manner in which Egyptian art manifested itself was in the erection of obelisks, or carved monolithic shafts of stone. One of these is the famous Cleopatra's Needle in Central Park, New York. This is of granite, 57 ft. in height, and its transportation from Egypt and erection in New York were considered quite a triumph of modern engineering. And yet this is but a moderate example of this style of work. In front of the Lateran Palace, in Rome, there is a monster shaft of red granite, 105 ft. high and weighing 430 tons. This was originally erected by King Tutnes III. (B.C. 1597-60), at Thebes, and was removed to Rome by Constantius, 357 A.D. It was overthrown and broken into three pieces before it was erected on its present site by Sixtus V., in 1587. The next largest obelisk is at the ancient Heliopolis, near Cairo, which measures 97½ ft. in height and 8½ ft. square at the base. This is of rose granite from Assuan, and was erected by Queen Makere about 1500 B.C. An inscription records that it was made in seven months, surely a remarkably short time for so great an achievement in quarrying, stone-cutting, and engineering.

If linear dimensions alone are taken into account, the Lateran obelisk undoubtedly holds the record, but as to mass and general magnitude, nothing in the way of quarried stones will compare with those that were used in the temple of the sun at Baalbec, in Syria. The remains of this wonderful structure still stand in a fair state of preservation. It is made up entirely of enormous blocks of stone laid up in dry masonry with close-fitting joints. The base courses of this temple are of blocks ranging from 20 ft. to more than 60 ft. in length. They are all surpassed, however, by a block which was cut from the ledge, squared up and partly removed from the quarry about half a mile from the temple itself, but left there when the work was finally suspended. An idea of its size can be gained from the accompanying data, but the exact statistics make the work of the ancient artisans even more remarkable. This Block has the almost incredible dimensions of 75 ft. by 18 ft. by 15 ft., and weighs fully 1,500 tons.

In recording the largest blocks quarried, the reference is, of course, to those that have been not alone broken off from their beds, but have also been removed from the pit, dressed, and erected. With modern explosives, drills, and quarrying apparatus, it is no unusual thing for a mass of rock weighing many thousands of tons to be broken loose and overthrown, but these great blocks are cut into smaller pieces before being removed and worked. About the year 1875, the proprietor of the Prentice brownstone quarries, in Michigan, quarried a single shaft of stone slightly over 100 ft. in length. It was intended to use this as a display at the Centennial Exposition in Philadelphia. It was found, however, that it would be impossible not only to remove this from the pit, but also to transport it to Philadelphia. It was, therefore, broken up into smaller sizes for commercial use. No one would be bold enough to declare that modern ingenuity would find it impossible to equal the gigantic blocks that find a place in the Temple at Baalbec, but they are likely to stand for all time as the record in stone quarrying.

A Canadian Quarry for Every Purpose

The Origin and Mineral Composition of the Chief Canadian Building Stones, Manner of Occurrence, Variations and Classifications

THERE is scarcely any variety of stone which may not be used for building purposes. Cheapness and accessibility often outweigh all other considerations and, where time is limited, are the chief and controlling factors. In a restricted sense, building stones fall into four groups designated as follows: (1) Granite and its allies, the igneous rocks; (2) Sandstones and related rocks; (3) Limestones and related rocks; (4) Slates.

By exceptional beauty, rarity and adaptability, many members of the above groups may pass over the indistinct line which divides building from ornamental stone. On the other hand, the so-called ornamental stones pass by a similar insensible gradation into gem stones. Ornamental stones, therefore, constitute a group, which is not clearly defined either scientifically or economically.

Some of the more important essential minerals of igneous rocks are briefly described below.

Quartz

Quartz is a crystallized form of dioxide of silicon, and is one of the commonest substances known. Besides being a constituent of many igneous rocks, it forms the bulk of common beach sand, as well as the solid sandstone rock. It is the hardest of the common minerals and will cut all those referred to below. It is normally colorless, like clear glass, but may be milky white or tinged with various colors, as pink, grey, and blue. The superior hardness of quartz, as well as its resistance to decay, renders it a very permanent substance, and it persists in almost unaltered form after the other minerals have disintegrated. Quartz is an essential constituent of many igneous rocks, particularly of granite and prophyry. Its presence in proper amount renders such a stone hard and permanent, but an excess causes difficulty in chiselling and consequently an increase in the cost of working.

Morrison Quarry Company's Masson Quarry, near Montreal.

Feldspar

The feldspars are complicated compounds of silicic acid with lime, soda and potash, and may be grouped in two divisions based on the substance combined with the silicic acid. In one case this substance is potash and in the other soda or lime, or both soda and lime. Owing to the ease with which feldspar cleaves, it is often filled with incipient cracks which allow the penetration of water, whereby decomposition is more readily effected. It sometimes happens that the feldspar crystals of a rock are so large or constitute so great a portion of the whole mass, that the quarrying of the rock becomes an economic possibility purely on account of the feldspar it contains.

Mica

Chemically, mica is a complicated compound of silicic acid with several other substances, particularly potash, magnesia, and iron. Mica is a common constituent of rocks, particularly of granite, the color of which is more or less controlled by the amount and color of the mica present.

Pyrite

Pyrite or iron pyrites is a compound of iron and sulphur, which usually crystallizes in cubes of bright, yellow, metallic color; its popular name is "Fool's gold." Pyrite in exterior building stone decomposes easily, resulting in unsightly stains. Its presence in small quantity is not prohibitive for inside construction, but for exteriors any appreciable amount is to be regarded with the gravest distrust. It is a fairly common accessory constituent of rocks, not only of the igneous types, but of other kinds as well.

Igneous Rock

Igneous rock is formed from molten matter which has consolidated either into minerals or glass, or both. Many classifications of a more or less satisfactory nature have been devised; but as yet all sorts of gradations are known to exist between the various types. Some of the more common varieties employed as building stone are classified below:—

Granite—The term, "granite," has been used in various senses and has been made to include many different stones; it has even been considered synonymous with "igneous rock." The physical character of a rock depends on two things—its mineral constituents and its structure. In a typical granite the constituent minerals are quartz, orthoclase and mica; the first two are always present, while the mica is frequently replaced by augite or hornblende. In its structure, granite is composed entirely of minerals; there is no glass or uncrystallized material between the constituent grains. Further, the various minerals are of approximately the same size. Variations in the size of the grains produce granites varying from extremely coarse examples with crystals of an inch or more in length down to those in which the grains are of microscopic size.

As the different minerals possess different colors, it is apparent that the relative amounts of these minerals is an important factor in determining the color of the rock as a whole. Granites are usually classified as grey or red, but a whole series may be selected ranging from almost white to a deep, bright red. In addition to the essential minerals, granites are prone to contain accessory constituents, such as garnet, pyrite, magnetite, hematite, and many others.

Prophyries—The term "prophyry" was at first employed to designate all those igneous rocks in which certain of the crystals are conspicuously larger than the rest. Modern usage, however, has somewhat restricted the use of the term, but the adjective, "prophyritic," is still applied to all rocks in which some of the minerals are conspicuously larger than the rest. Many of the prophyries, particularly those with large, bright-colored prophyritic individuals embedded in a darker ground mass, are of unusual beauty when polished, and are much in demand for decorative purposes.

Greenstone—"Greenstone" has been applied to rocks of very different composition and structure and has no real significance. It will be continued to be used, however, because it aptly describes a series of rocks presenting a dark green or black color, the differentiation of which is often attended with considerable difficulty. In composition they are all characterized by the practical absence of both quartz and orthoclase. The minerals which compose the greenstones are more prone to decay than those of the granites. They do not generally appeal to architects for building.

Sedimentary Series

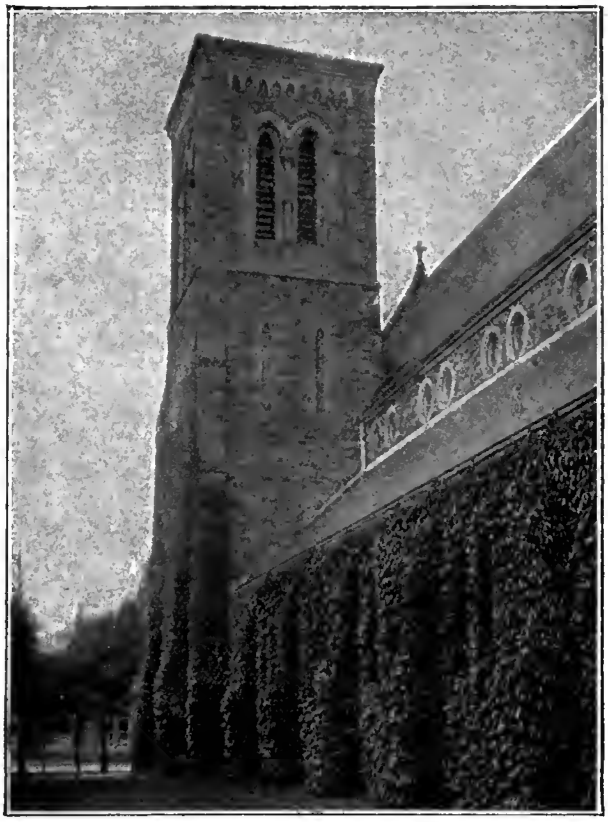
To the sedimentary series are ascribed all those deposits which have accumulated at the bottom of bodies of water. It is obvious that these materials must have been derived from the land surface and transported into the sea or lakes, either by solution in the water or by mechanical carriage in the rivers or streams. It is further obvious that any of these materials which make up the igneous rocks may be removed on the decay of those rocks and thus go to make up the sedimentary series. The more or less complete decomposition of the original minerals of the igneous rocks results, however, in the formation of new minerals which go to make up the sedimentary series. Further, after the sedimentary rock is formed, other new minerals may originate by chemical changes within the rock. Of the sedimentary or stratified rocks formed from the solidification of the masses of material borne into the sea the more important are described below:—

Sandstone—The comminuted mineral particles, derived from the original igneous rocks, and washed down by streams into the ocean, build up layers of material which eventually become rock. In distributing these particles, the well-known sorting power of water comes into play, whereby the sand-like grains are separated, on the one hand, from the coarser fragments, and on the other, from the finer particles of kaolin. The sandy portion consolidation becomes sandstone. The character of sandstone depends on the mineral character of the component grains, the size and shape of the grains, their arrangement within the rock, and the nature of the cementing material binding them together.

Particles of quartz form by far the most desirable constituents of sandstone; feldspar is also frequently present. Among the less frequent mineral grains found in sandstones may be mentioned, hornblende, chlorite, garnet, magnetite, and calcite. In the best sandstones the grains are arranged uniformly throughout the mass. Frequently, however, the coarser and finer particles are arranged in layers, thus giving a striped appearance to the stone, together with a pronounced tendency to break parallel to the various sheets. Of equal, if not greater, importance than the constituent grains themselves, is the nature of the cementing material by which the grains are bound together. This cementing material may be silica, carbonate of lime, oxide of iron, or clay. Sandstones are usually spoken of as siliceous, calcerous, ferruginous, or argillaceous, according to the nature of the cementing material. Siliceous sandstones have the greatest strength, but they are frequently so hard that they cannot be chiselled, except at prohibitive cost. Calcareous are soft and may be worked with comparative ease; but succumb readily to the action of weather. Argillaceous sandstones are usually dull and unattractive, and are liable to absorb water and disintegrate under the action of frost. In color, sandstones are extremely variable, ranging from almost white to dark brown; grey, buff, drab, bluish, and greenish types are common.

Limestone

Limestone is composed essentially of carbonate of lime which has been deposited on the floor of bodies of water and has subsequently hardened into rock.



Niagara Limestone, St. Patrick's Church, Hamilton, Ont.

The precipitation of the lime may have been effected directly from the water or by the agency of animal or vegetable life, that is, the limestone is a chemical precipitate, or it is composed of the shells and other hard parts of animals, as well as the hardened tissue of certain plants.

Compact limestone is only occasionally pure carbonate of lime, in which case it has a high value for the manufacture of chemical products. Any considerable amount of clay is not desirable in a limestone as it softens the rock and renders it more liable to disintegration. A very fine grained, uniform, magnesian limestone, with a small amount of clay, is known as lithographic limestone. Hydraulic limestone contains a considerable amount of clay and, when burnt, yields a cement capable of setting under water. A rock so diversified as limestone must necessarily present many different colors. White, grey and drab are the prevailing tints, yellow, blue, and green are of frequent occurrence.

Metamorphic Rocks—Rocks of either igneous or sedimentary origin are often subjected to such severe treatment in the long course of their geological history, that the original character is much altered. The folding and crushing of the earth's crust, the immense weight of overlying material, and the contact with hot molten rock from the interior may be mentioned among the numerous causes contributing to the change. Such altered rocks are referred to as "Metamorphic."

Marble—Although the term "marble" is frequently applied to handsome varieties of sedimentary limestone, particularly the fossiliferous examples, it seems advisable to restrict the name to the metamorphosed limestones—to those in which the crystalline structure has been induced by metamorphism. The term has been used in a general sense as any kind of limestone capable of receiving a polish. Marble, in the narrower sense, is a fine, even aggregate of calcite crystals which has been produced from ordinary limestone by the action of heat and pressure. When pure it is snow white and is known as statuary marble. The different colored marbles sometimes present the different hues, pink, red, grey, blue, etc., throughout the mass. The arrangement of the coloring matter is due to the aggregation of the impurities originally present in the limestone and their conversion into new minerals by the process of metamorphism. Marble is found only in regions which have been subjected to severe strain, in consequence of which the originally level beds of limestone have been bent and folded to such an extent that they are sometimes vertical instead of horizontal in position.

Slate

Highly metamorphosed beds of shale which have been subjected to a strong lateral pressure become much hardened and at the same time acquire a tendency to cleave in a direction at right angles to the line of pressure. It should be clearly understood that the familiar sheets of slate are not the result of bedding planes, but are consequent upon the development of "slaty cleavage," which takes place in a direction in no way related to the planes of stratification. Slate deposits are, therefore, always found "standing on edge." They are usually of limited width, but may extend for miles along the direction of cleavage. Green to grey varieties are by far the more common, but purple, red and mottled slates are quarried to a considerable amount.

Field Stones

The loose stones so generously scattered over a large part of Canada and so universally used in the construction of foundations, and even dwelling houses and churches in rural districts, cannot be ascribed to any particular type. A great many different kinds of stone may be obtained from among these loose pieces within a very limited district. All these materials have been derived from the northward of the localities in which they are now found and have been borne to their present position by the action of ice during the comparatively recent "Ice age" or "Glacial period."

Occurrence of Various Building Stones

Present Knowledge More Complete with Respect to Eastern Canada—Large Deposits Widely Distributed

THE ensuing description will deal with the occurrence of the more important building stones, according to their geological formation, in Ontario, Quebec, and the Maritime Provinces. The description will include a brief summary of different areas that have been actually exploited for the production of building stone.

ONTARIO

Sandstone

The sandstones quarried in Ontario are obtained principally from three formations—Potsdam-Beekmantown, the Medina, and the Oriskany. Small quantities have also been obtained from the Chazy, and they are likewise known to occur in the Trenton.

Potsdam-Beekmantown—The advancing ocean, which encroached on the old Archaean continent in early geological time, caused a shore line deposit of sandstone to be formed. As this oceanic advance continued through both "Potsdam" (Upper Cambrian), and "Beekmantown" time, and as the sandstone rarely carried any distinctive fossils whereby its age may be determined, it is usual to designate the stone by the term, "Potsdam-Beekmantown" sandstone. The actual outcrops of the rock are always found adjoining the Archaean. To the westward the fringe of sandstone has been largely covered by later deposits, and, to the eastward, its outcrop is very irregular. The following geographical areas of Potsdam-Beekmantown sandstone are well known: South Frontenac, Brockville, Rideau, Smith's Falls, Perth, Mississippi, Nepean, and Prescott.

The stone of the Potsdam-Beekmantown is mostly hard, white, and flinty, with brown spots and checks; the workable varieties are the exception to the above rule. On the whole, they are hard and not adaptable to fine work. Much of the stone makes excellent rubble and random coursing and for rock-face work it is very desirable.

Medina—The sandstone band of the Medina formation has an average thickness of 12 feet; it represents a shore deposit at the opening of "Silurian" time. The quarries exhibit irregular bedding which has proved a great hindrance to the profitable extraction of the stone. Most of the beds are fine grained and present, roughly, three types, brown, white or grey, and mottled. This stone is found chiefly in the Niagara, Milton, Credit Valley, and Orangeville areas.

Oriskany—After the deposition of the Salina beds there was a considerable period of erosion during which masses of sand were distributed by the wind over the low denuded country. The advancing sea rearranged these accumulations of sand to a greater or less extent, and produced a series of beds known as the "Oriskany" formation. This series is seen near Waterloo, on the Niagara River, but the only area of any importance occurs in the townships of Oneida, North Cayuga, Walpole, and Townsend, in Haldimand and Norfolk Counties.

Limestones

The Province of Ontario is rich in limestones of various kinds, some of them well adapted to building purposes, others more particularly to heavy construction. East of the Archaean axis, building stone is obtained from the Beekmantown, the Chazy, the Black River, and the Trenton formations. West of the axis the chief formations yielding good stone are the Black River, the Trenton, the Niagara, the Guelph, the Onondaga, and the Hamilton.

Beekmantown—This formation consists chiefly of different types of dolomitic and sandy limestones and is found in the following areas: the St. Lawrence area, around Brockville and Prescott; the Mountain area, around east Dundas; the Lanark area, around Smith's Falls, Carleton Place, and Almonte. This formation produces a heavy, dark colored limestone suitable only for heavy construction, a crystalline limestone with varying amounts of sand, extremely hard but durable, and a granular crystalline dolomite of brownish color, softer and more desirable as a building stone.

Chazy—After the "Beekmantown" era, another great advance of the sea marked the "Chazyan" time. The upper beds of this formation, the limestone portion, contains some fine stone adapted both to heavy construction and to architectural purposes. The distribution of quarries of this formation is indicated in the following division of areas: the Central Dundas, the Sheek Island, the Prescott, the Ottawa, the Lanark, the Eganville, and the Pembroke.

Four rather distinct types are produced from this formation: (1) a hard, heavy, dark-colored stone, hard to chisel, adapted to rock-face work and heavy construction; (2) a lighter colored grey stone; (3) a fine encrinal limestone of light blue-grey color—this is a high grade stone, easy to chisel, of excellent appearance, and suitable to either heavy construction or architectural work; (4) a fine grained, dark-colored, soft stone, with a muddy aspect on weathering, used for bridge work.

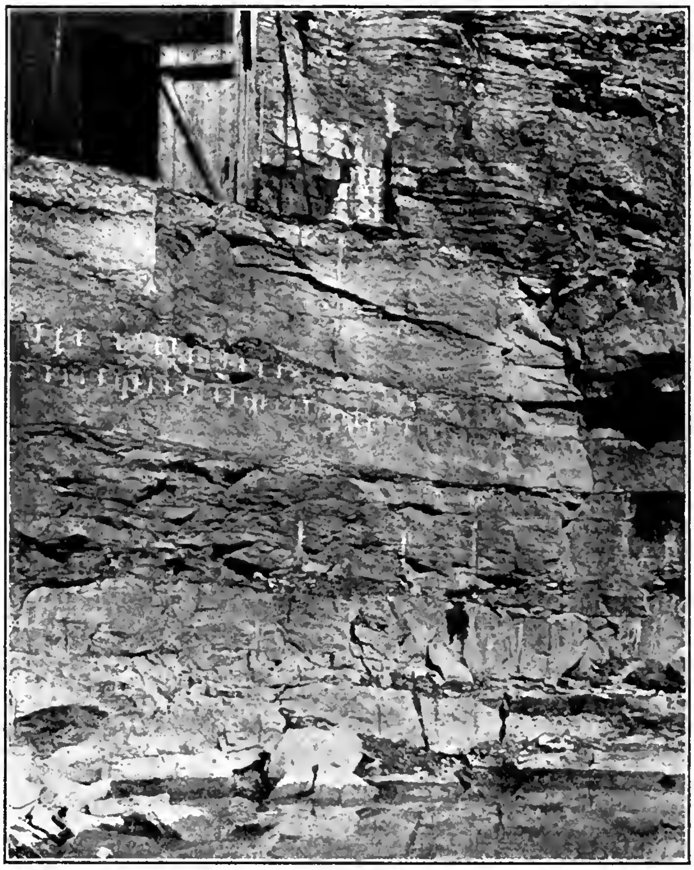
Black River—Overlying the Chazy limestones and shales are a series of beds which represent later stages in depositions of the same marine invasion. The Black River formation consists of dark and heavily bedded limestones, usually of quite limited thickness and geographical extent, and of lighter colored, compact stones of lithographic character. The quarries of this formation may be conveniently grouped under the following geographical areas: Stormont, Glengarry, Ottawa River, Carleton, Dirleton, McNab, Renfrew, and Western. This latter area constitutes a narrow band extending along the western flank of Archaean rocks from Kingston to Georgian Bay, comprising the following districts: Kingston, Napanee, Belleville, Crookston, Madoc, Marmora, Burnt River, Longford, and Georgian Bay. The stone is mostly a fine grained, compact variety, approaching the lithographic in character.

Trenton—Although the rocks of this formation are wide spread, there are not many quarries throughout its whole extent. The only important quarries now in operation are those near Ottawa. The following areas of Trenton rock may be recognized: the Ottawa River, Stormont, Glengarry, Carleton, Renfrew, and the Western, which consists of the following districts: Belleville, Prince Edward County, and Peterborough.

Niagara—The limestones of this formation constitute the upper part of the escarpment reaching from Queenston Heights to the Bruce peninsula. Along this line numerous quarries have been operated from which excellent stone for both heavy construction and for architectural purposes, have been obtained. The Niagara stone is generally of a dolomitic character, usually of a light color with a yellowish cast, and is more porous than the stone from the older formations. The quarrying industry is centred around the following points: Queenston, Thorold, Beamsville, Hamilton, a central area, and Owen Sound and Wiarton.

Guelph—Owing to the heavy covering of soil, the exact boundaries of the Guelph formation are difficult to determine. The formation consists of magnesian limestones which may be recognized by their light yellowish color and porous character. The following areas may be recognized: Galt—Guelph, Fergus—Elora, and Glenely. This stone is quarried with facility, but the beds are irregular, requiring considerable work to make the stone suitable for coursing.

Onondaga—The Onondaga is the lower formation of the Devonian system in the western Peninsula of Ontario. There are but two extensive quarries actually producing stone at the present time, both situated at St. Marys. The following areas may be established: Hagersville, Port Colborne, Buchville, St. Marys, Amherstburg, Pelee Island, and Kincardine. Although the extent of this formation is large, rock exposures are by no means common, as the country for the most part is deeply covered with soil. The most important quarries are around St. Marys, where a grey limestone of semi-crystalline character and good chiselling qualities is produced. On weathering it assumes a lighter color, but the whitening is never so pronounced as in the case of the Black River stone.



Montreal limestone—Martineau's Quarry, Mile End Group, Montreal.

Hamilton—Actual exposures of this formation are so interbedded with shales that profitable quarrying operations could only be effected with a brick and tile plant. Limestone may be obtained at various points along the Aux Sables River, in the vicinity of Thedford, and on the shore of Lake Huron.

Granites

Although gneiss and granite occur over wide areas in the Archaean region of Central Ontario, they have not been exploited to any great extent. The actual total production is insignificant and quite out of proportion to the possibilities of the country. The only present production of granite is from a region northwest of Gananoque, on the St. Lawrence. Gneiss has been obtained from North Bay, Gravenhurst and Parry Sound. With the granites are included the syenites which occur in abundance in Haliburton, Peterborough, and Hastings. With the exception of the St. Lawrence area, granite deposits have been worked little or not at all.

Crystalline Limestones and Marbles

In the southeast portion of Hastings, Lanark, Frontenac, Leeds, Haliburton, Renfrew, Peterborough and Victoria, are extensive belts of crystalline limestone. Roughly speaking, there is about 100 square miles of territory formed of rocks of this type. While most of the stone is too coarse and friable, or too impure for structural work, some of it, on the other hand, is so fine, and so beautifully marked as to deserve the name of marble.

QUEBEC

Limestones

The limestones quarried in the Province of Quebec for purposes of construction are obtained to a very large extent from the Chazy and Trenton formations. Beekmantown stone is employed locally, and the limestone of "Silurian" age in the peninsula of Gaspe is used in very limited amount. All the finer grades are derived from the Chazy and Trenton formations and are semi-crystalline, greyish stones in which the chief variation is the relative development of their dark-colored, argillaceous partings.

A second type is a more thinly bedded, less crystalline and much darker stone, suitable for rock-face work and common building. Beekmantown limestone, as developed in Quebec, is usually of poor color and does not represent possibilities beyond local application for foundations.

Chazy and Trenton—Owing to the similarity of the limestone, these two formations are considered together. The following geographic areas, certain of which are subdivided into districts, may be recognized: Montreal area, covering Caughnawaga district, Pointe Claire district, St. Laurent district, Bordeaux district, St. Martin district, St. Vincent de Paul district, St. Francois de Salles district, and the Montreal district which includes Villeray group, Mile End group, De Lorimier group, Iberville group, Nicolet group, Maisonneuve group, Cote St. Michel group, Lachine group; St. Johns—Grande Ligne area; St. Dominique area; Joliette area; St. Cuthbert area; St. Marc des Carrieres area; Grenville area; Hull area; Roberval area.

Beekmantown—The Beekmantown formation, formerly know as the calciferous, consists largely of brownish dolomitic limestones frequently with an admixture of sand. The stone is usually of a rough character and subject to rapid weathering. Good stone of this formation has been raised in Ontario, but the Quebec exposures are less satisfactory. This formation occurs south of Lake St. Louis in two wide areas, but despite its wide extent, the quarries in this formation in Quebec are insignificant.

Silurian System—Silurian limestones that have not yet been satisfactorily ascribed to formations are quarried at several widely scattered points in the province. The most important of these is the group of flagstone quarries in Wolfe County.

Sandstones

Sandstone of a quality suitable for structures of importance is of rare occurrence in the Province of Quebec, but more or less desirable stone has been raised from some six different formations. The nature of the stone is quite distinct in these different formations and is briefly mentioned below:—

Potsdam-Beekmantown—a hard, white sandstone, almost a quartzite in places, usually much disfigured with iron stains, adapted to rock-face work; Sillery—a hard, compact stone of greenish color, very solid and durable, but too hard and rough for fine work; Trenton—a coarse-grained, calcareous sandstone; Niagara—a coarse-grained, friable stone, subject to iron stains on weathering; Devonian—a fine-grained, homogeneous, reddish sandstone, by far the most desirable of the Quebec sandstones; Carboniferous—a coarse, friable type of olive-green, not comparable with the better varieties of Carboniferous sandstones of the Maritime Provinces.

Potsdam-Beekmantown—This formation is the oldest of the Palaeozoic series represented in the province. Its greatest development is in Vaudreuil, Soulanges, Two Mountains, Beauharnois, Chateauguay, and Huntington, whence it extends as a narrow band eastward along the Pre-Cambrian axis to the longitude of Three Rivers. A hard and durable sandstone exposed at numerous places, which has afforded an opportunity for numerous quarries for local building.

Sillery—The Sillery formation consists of a series of red and green shales with which are associated hard sandstones of varying colors. The formation has been so severely folded that the strata are now formed with vertical or highly inclined dips. It is developed east of the city of Quebec, on the Island of Orleans, and over a very extensive area which stretches from the south shore of the St. Lawrence below Quebec, to the international boundary. The sandstones have been seriously quarried only in the vicinity of Quebec and Levis. The stone is hard and not suited to fine carving, but it is very durable and retains its dark greenish color almost unaltered after years of exposure.

Trenton—The Trenton limestones on the north shore of the Lower St. Lawrence, are underlaid in places by a basal sandstone belonging to the same series as the Trenton limestones. Due to excellent shipping facilities extensive quarrying was carried on in the Malbaie area at Murray Bay. This sandstone from Murray Bay is of a high order of durability.

Devonian—The Devonian sandstones of Gaspe have frequently been referred to as a source of supply for building purposes. The inaccessible nature of the interior of the Gaspe Peninsula has prevented the exploitation of these stones. The stone is a very desirable material on account of the fineness of grain and the uniformity of color, which is very like that of the brown Credit Valley stone of Ontario.

Carboniferous—Sandstones of the Carboniferous formation which are so largely quarried in the Maritime Provinces, are sparingly developed at a few points along the north shore of the Baie de Chaleurs, in the Province of Quebec. The most important belt lies in the vicinity of Pointe a Bourdeau, opposite Campbellton, N.B.

Granites and Gneisses

True granites are composed of three mineral constituents—orthoclase feldspar, quartz, and mica, or some other ferro-magnesian mineral. When a rock of this nature presents a laminated structure with the constituents more or less distinctly arranged in layers, it is known as "gneiss." By a failure of the quartz constituent, granite passes into "syenite."

Granite and its allies, are quarried in two general regions which are very dissimilar geologically. The ancient Pre-Cambrian crystalline area of northern Quebec contains enormous ranges of granite and granitoid gneiss. In this area the following quarry areas may be established: Riviere a Pierre,, Roberval, Ottawa, Argenteuil, and St. Jerome.

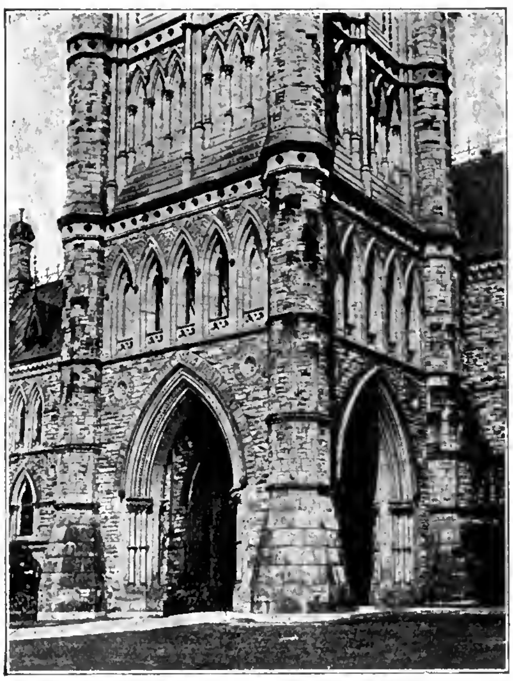
The second general region is in the southern part of the eastern townships where granite is quarried from igneous masses of later age than the surrounding sedimentaries. The important areas may be arranged as below: Stanstead, Magoons Point, Megantic, and Stanhope.

Black Granites

The term, "black granite," is used by quarrymen to designate the dark-colored, igneous rocks in general. The great majority are diorites, diabases, etc. The important sources of black granites in the Province of Quebec are the Monteregian Hills, a series of intrusive, igneous masses which broke through the Palaeozoic region in late Devonian or early Carboniferous time. The most important of these are: Montreal Mountain, Mount Johnson, Yamaska Mountain, and Sheffore, Brome, Boloeil, Rougemont, and Montarville mountains.

Marbles

The term, "marble," in the narrow sense is confined to crystalline varieties of limestone which have acquired their characteristic structure by the metamorphic action of natural agencies such as heat and pressure.



Nepean Sandstone—Main Entrance, Parliament Building, Ottawa.

Marble occurs under two general conditions in the Province of Quebec: first, in the form of bands in the great Pre-Cambrian region of the north and in the narrower Pre-Cambrian belts of the Eastern Townships; second, in the form of metamorphosed zones in the sedimentary limestones of the Palaeozoic and in the peninsula of Gaspe. The more important occurrences of these two types are: Pre-Cambrian marbles—in the Northern Quebec area (Portage du Fort, Pontiac County; Ste. Thecle, Champlain County), and in the Eastern Townships (South Stukely and Oxford Mountain); Palaeozoic marbles—St. Lin, Terrebonne County; Phillipsburg, Missisquoi County; Dudswell, Wolfe County; St. Joseph, Beauce County, and Port Daniel, Bonaventure County. The marble industry is gradually becoming an important factor in the development of the mineral resources of the province.

MARITIME PROVINCES

Sandstone

The various members of the Carboniferous system, which is so extensively developed in the Maritime Provinces, contain numerous beds of sandstone, of which no inconsiderable number are sufficiently homogeneous and of the requisite texture to yield excellent building material.

The rocks of this system, as developed in the Maritime Provinces, are usually classified as Upper, or Permo-Carboniferous, Middle Carboniferous, and Lower Carboniferous. While sandstone has been quarried from all the subdivisions, the Permo-Carboniferous and the Millstone Grit of the Middle Carboniferous, have yielded practically all the commercial output. These two formations will be considered together, using as a basis of classification the geographical areas, which are, beginning in the north of New Brunswick and continuing south and east to Capė Breton, more or less distinctly marked off into the following quarries: Chaleur Bay, N.B.; Miramichi, N.B.; Buctouche, N.B.; Shediac, N.B.; Fredericton, N.B.; Shepody Bay, N.B.; Cumberland Basin, N.B.; Wallace, N.S.; John River, N.S.; Pictou, N.S.; Monk Head, N.S.; Boularderie Island, Cape Breton; Sydney, N.S.; Whycocomagh, N.S.; Port Hood, N.S., and Prince Edward Island.

The sandstones from these various areas, while alike in some respects, show great variations in color, in texture, and in the character of the cementing material. In a broad way, they may be classified into two groups—olive-green and grey sandstones, and red and brown sandstones.

Areas producing only olive-green or grey stones are: Chaleur Bay, Miramichi, Wallace, Shediac, Pictou, Boularderie, and Sydney. Areas producing only red or brown: River John, Monk Head, Whycocomagh, Prince Edward Island. Areas producing both olive-green and red or brown stone: Buctouche, Fredericton, Shepody Bay, Cumberland Basin, and Port Hood.

In texture the olive-green and grey sandstones vary from fine to coarse, the finest grained examples occurring in Chaleur Bay, the Pictou and the Port Hood areas. The general average texture of the typical olive-green is rather coarse. Nearly all the stones can be carved and drilled with reasonable facility. The red and brown sandstones vary from a dirty brown to a very brilliant red. In texture the brown stones are decidedly coarse; the medium toned red from Sackville and Amherst are of medium grain, while the argillaceous red stones of a brighter hue from the River John and Inverness County, are of fine grain.

Granites

Extensive masses of granite, more or less suitable for construction, occur in several areas in both Nova Scotia and New Brunswick. In texture these granites vary from extremely coarse to very fine grained, and in color from bright red to a light grey. Notwithstanding the wide extent of the exposures and undoubted value of many of the granites, there are only five locations in which stone is being continuously quarried: St. George, N.B.—producing red, pink, and light grey, coarse grained, monumental stone; McAdam Junction, N.B.—a coarse grey stone for building only; Spoon Island, N.B.—a pinkish and greyish, medium grained, monumental and building stone; Metam, N.S.—a fine grained, grey, monumental and

Sackville Sandstone—Fireplace.

building stone; Halifax, N.S.—coarse grained to prophyritic, greyish, building stone.

The New Brunswick granites may be observed in the following areas: Bathurst, McAdam, St. George, Spoon Island, and St. Stephen. The Nova Scotia areas consist of: Nictaux, New Germany, Shelburne, Halifax, Greysborough, and Cape Breton. Several large masses of granite appear along the south-western boundary of New Brunswick, extend north and east and appear as isolated patches on the shore of Chaleur Bay.

Black Granites

Many of the dark-colored igneous rocks, such as diabase, diorite, gabbro, etc., are used for monumental purposes. The great toughness of this class of stone and the consequent difficulty of working, has restricted its use; but at present there seems to be a constantly increasing demand. The occurrences of these stones are numerous, but for the most part unimportant. Actual production is confined to a limited area near Bocabec, in Charlotte County, N.B. Rather excessive fracturing, together with the occasional presence of lighter colored stringers, and other blemishes, causes a large amount of waste.

Limestones

The Maritime Provinces are not rich in beds of limestone suitable for the purposes of construction and at the present time there is practically no commercial production for constructional purposes. Certain of the limestone beds have been worked in the past for lime making, the demand for flux in the iron furnaces of Sydney and New Glasgow having led to the opening of them.

Crystalline Limestones and Marble

The term "marble" is used here to indicate all calcareous stones of sufficient beauty to be employed for purposes of decorations. Ordinary limestones pass into marbles by the assumption of a crystalline structure or by the possession of agreeable and variegated colors, together with fineness of grain. In the Maritime Provinces, both types are represented—the former by the crystalline limestones of the "Pre-Cambrian" age, and the latter more particularly by metamorphosed beds of Carboniferous limestone. No marble of either type is now being quarried, but the crystalline stone is extensively used for lime burning and for flux. The crystalline stones are for the most part, coarse in grain and possessed of a strong banding with variations in color; they are largely quarried for lime burning at St. John, N.B., and for flux at Marble Mountain and George River, N.S.

Slate

Extensive areas of slate occur in both Nova Scotia and New Brunswick, in those regions where the clay sediments of Cambrian, Cambro-Silurian, and Devonian have been subjected to severe metamorphism.

Although slate is commonly regarded as a rough substance, it is nevertheless a very tender one, and is very susceptible to destruction under the action of water. There has, however, in spite of the extensive area, been no production for some years.

Montreal Rejects Engineers' Suggestions

By the casting vote of the Mayor, the Montreal Board of Control have rejected a motion calling for the appointment of Mr. J. G. Sullivan, engineer of the C.P.R., and Mr. A. St. Laurent, deputy minister and engineer in chief of the Public Works Department of the Dominion, acting in conjunction with Mr. P. Mercier, the chief engineer of the city, to study the aqueduct project, to give details of the estimated cost to carry out the scheme in its entirety, and of separate estimates for different branches, and to advise if the project might with advantage be modified or changed. The scheme has been the subject of much adverse criticism, and recently many prominent engineers petitioned the Controllers to appoint independent engineers to report on the proposed hydro-electric development portion, for obtaining 10,000 h.p. for pumping and lighting purposes. It was contended that the scheme had never been fully reported on and that there were doubts as to its economic value. The vote of the Controllers is a virtual rejection of this petition.

The Dominion Bridge Company will be asked to prepare plans for new headgates required for the enlarged Montreal aqueduct. The estimated cost is just over $100,000.

Machinery and Tools Used in the Stone Trade

Modern Steam and Electric Power Machines Now Utilized almost Universally—Rapid Developments in Recent Years

THE implements used in the stone industry consist essentially of hammers, chisels and drills, and when power is available, a number of special appliances which greatly reduce the cost of production.

Drills

Ordinary drills are made from steel bars of any desired length. The bit is made by drawing out the steel to a single sharp cutting edge a little wider than the steel, which is usually ¾ in. to ⅞ in. in diameter, although much heavier steel is occasionally used. Such drills are usually held and turned by one man, while another, or even two, strike with sledges. When power is available, machine drills are used. The machine rock drill has done more to render possible the excavation of rock on a large scale than any other appliance. The drill consists essentially of a cylinder in which the piston is driven down with the full force of the power available, whether steam or compressed air. Recovery is effected by the same agent. Drills are made varying in weight from 100 to 1,000 lbs., and are capable of sinking to depths up to 30 feet. The drills may be single bitted, but the cutting face is usually made either + or × shaped, and, as in hand drilling, smaller bits are used as the hole deepens.

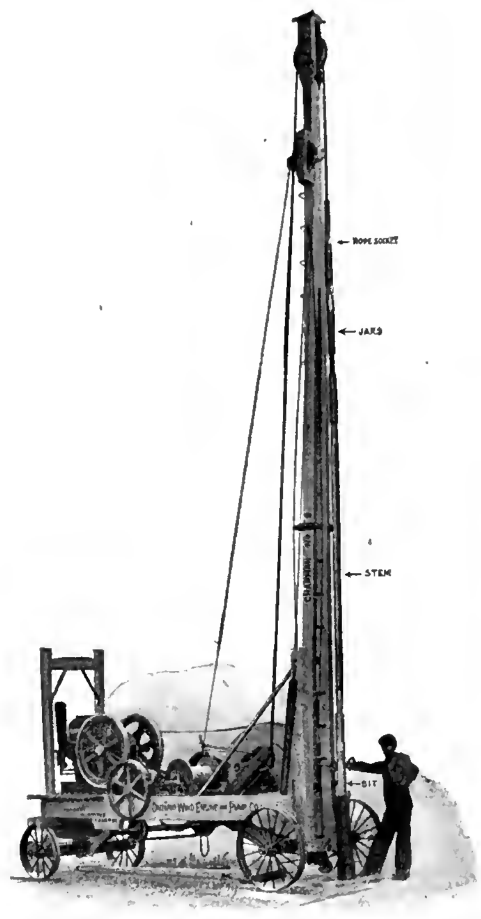
Rock drills are usually too heavy to handle without some support; and so they are mounted on some special contrivances to suit the work in hand. The most commonly used mount is the tripod with weighted legs. In order to drill a number of parallel holes along a straight line, the instrument is mounted on a "quarry bar," which consists essentially of a heavy bar of steel supported at each end by two adjustable legs. The drill is moved along this bar, which can be placed either in a horizontal or inclined position, by a rack and pinion. A lighter type of drill thus mounted is usually employed for horizontal holes made with the intention of "raising" a block. This operation is known as "gadding" and the instrument as a "gadder." In very hard rock, such as granite, where a channelling machine cannot be employed to advantage, channels are cut by the use of rock drills and quarry bars, the holes being drilled as closely as possible to present a minimum core area. Quarry bars are also used for gadding, usually with a light type of drill. Rock drills are commonly actuated either by steam or compressed air and in most cases are constructed to work equally well with either. More recent practice is to apply electricity to their operations.

Channelling Machines

A "channel" is a lineal cut of any desired length and of a depth up to about 15 feet. The width of the cut varies with the depth. Channels may be made with the rock drill and quarry bar. Instead of the rock drills, diamond boring machines travelling on an adjustable track are sometimes employed. The quarry bar and rock drill are still largely employed in granite quarrying, but for the softer stones—limestone, sandstone, and marble—the most modern direct-acting channelling machine is universally used.

The channelling machine consists essentially of a truck travelling on rails and provided with a chopping engine capable of delivering powerful blows as the truck is moved slowly along the rails. By repeated trips back and forward the cut is sunk to the desired depth. The cutting apparatus consists of a gang of drills, usually five, attached by special mechanism to the end of the piston rod. The drills are made of rectangular steel and are bolted together in a line with the channel. The drills are single bitted, but the cutting edges are arranged in a special manner.

In quarries where the product is to be used for crushing only, a more expeditious machine known as the "Well Drill" is generally employed. This consists of an equipment essentially the same in construction and operation as a pile driver, except that the heavy hammer is replaced by a long and heavy iron bar several feet in length and up to 5 in. in diameter. The lower end of this bar is fitted with a steel chisel. Successive blows are accomplished just as with the pile driver by raising the bar to a considerable height and letting it drop. With this machine a much larger opening is obtained, which admits of a larger charge of explosive.



The Well Drill is a later Development.

A new crushing plant has been installed by Walker Bros., Quarrymen and Contractors, of Thorold, Ont. Their quarries produce a very suitable stone for fluxing and for use in the manufacture of pulp.

Tools for Dressing Stone

AS the stone industry advances, the use of machinery and its finer development is very distinctly apparent. We note briefly the main equipment of a modern dimension stone dressing plant below:—

Hammers

The hammers used for dressing stone vary in design and shape for special purposes. Hammers for surfacing stone are made with a series of pyramidal points on the faces. These points may be 4, 9, 16, 25, or 36 to the square inch. The stone is brought to a smooth plane finish by the successive use of finer and finer hammers. The difficulty of keeping these tools sharp has led to the use of an improved form in which the cutting face is made up of a series of sharp edges, being the end of a series of steel plates. These plates are known as "cuts," which are bolted together and rest against a hardened steel "gib." These hammers are called "bush" hammers.

Chisels

No detailed descriptions of chisels will be attempted here. In all large plants the use of hand chisels has been greatly lessened owing to the introduction of pneumatic tools. The following are the commoner types of hand chisels: plain chisel or drove, with a sharp, straight cutting edge; pitching chisel, with a sharp, rectangular cutting face, used for trimming stone to a line; pointed, a tool with a pyramidal point, used in producing point work; splitting; toothed, like an ordinary chisel, with cutting edge toothed.

The chief forms used in the pneumatic tool are: plain chisel; cleaning up chisel; carver's drill; tooth chisel, with one or more rows of chisel teeth; double blade chisel, and a bush chisel. The bush chisel is made on the same principle as the bush hammer.

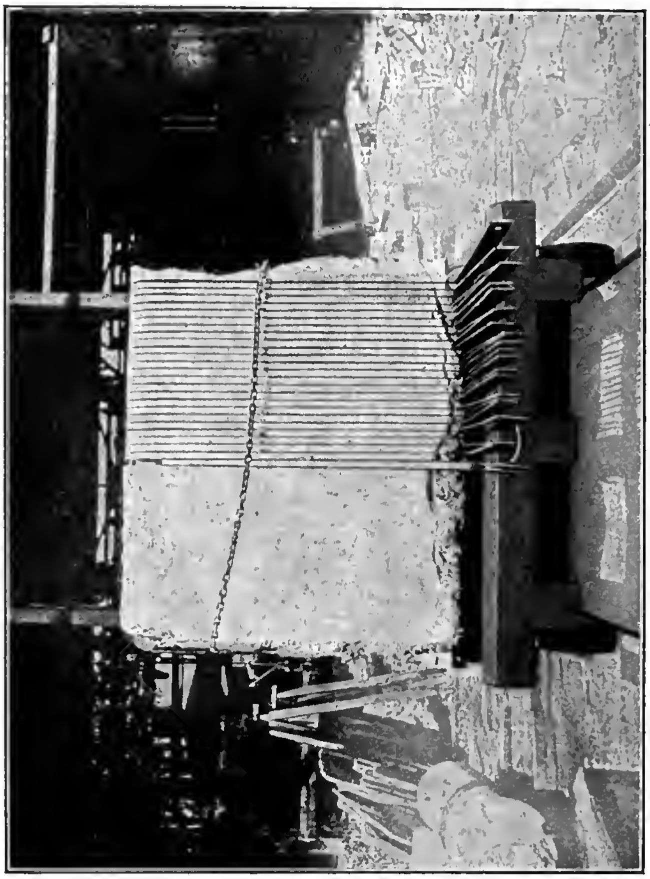
Gang Saw

The gang saw consists of a wood or steel frame with a horizontal steel sash suspended from the frame and free to swing. A reciprocating motion is given the sash by one or two pitman rods, which are driven by a crank. The frame is placed over a hopper-like opening which collects the water, sand, and stone dust as it flows from the saws.

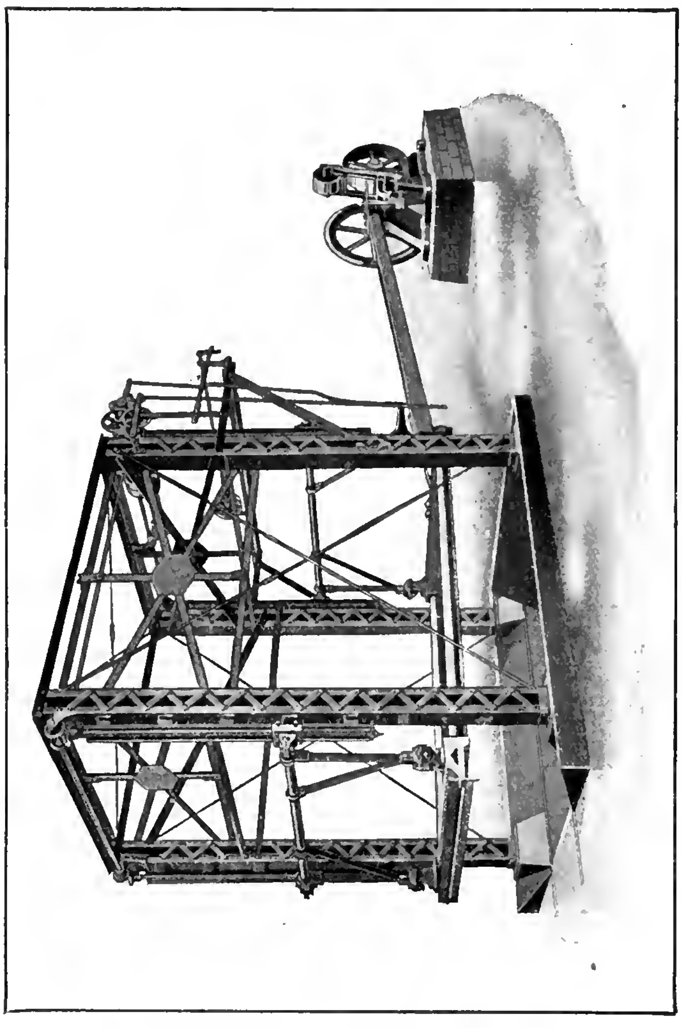
The actual saws, which are bands of soft steel, 3 in wide and ⅜ in. thick, are stretched between the head pieces of the sash and held in position by keys. They can be adjusted to cut to any desired spacing. The stone to be cut is placed over the hopper, beneath the sash, the saws adjusted, set in operation and a constant supply of water and sand fed over the stone by special distributers. The cutting is effected by the sharp sand which gets into the cuts and is ground between the saw blades and the stone. The overflow of sand and water falls into the hopper below the stone. This type of saw is used on limestones and marble On hard sandstone and granites the saw blades are heavier and are notched on the cutting edge; chilled shot or crushed steel is used instead of sand. Once started, the operation of a gang saw is automatic.

Rubbing bed

In smoothing the sawn blocks or slabs of the softer stones, the rubbing bed is used. This machine consists essentially of a round horizontal steel plate, which is given a rotary motion. The plates range



Block of Marble partly sawn into slabs on gang truck, with the saws left in place.



Patch Merriman Steel Frame Gang Saw.

from 4 feet to 14 feet in diameter, and run at about 45 r.p.m. The block of stone is placed face down on the rubbing bed, sand and water are supplied, and the stone left until sufficiently reduced. The finish produced by the rubbing bed is sufficient for outside work in marble and is known as the "sand finish."

Gritting and Polishing Machines

For further smoothing, the stone is taken from the rubbing beds to the gritting machines and thence to the polishers. These machines consist of horizontally rotating discs, to which different types of heads may be attached. These heads are blocks of abrasives arranged in a radial manner of different sizes with interspaces between them. The abrasives most generally used on the gritting machine are bricks of carborundum, of finer and finer grades as the polishing proceeds. Heads of black or Scotch hone are used for the final operation. The gritters run about 200 r.p.m. The polishers have heads of felt, usually about 20 in. in diameter, and operate at about 400 r.p.m. As in hand polishing, putty powder is used to produce the gloss.

Diamond Saw

The diamond saw is a rotating steel disc, with a number of carbons on its periphery. It is used for making single cuts for fitting together various pieces.

Planing Machine

Planing machines are devices whereby a block of stone may be moved to and fro on a horizontal bed, and at the same time be subjected to the cutting edges of chisels. These machines are very heavy and are usually driven by worm or screw gears.

Miscellaneous

Special drill machines, lathes for turning columns and other round work, counter-sinking machines, etc., are included in the dressing equipment, but their use is confined, in general, to the larger dressing plants.

Dressing Marble

Marble blocks from the quarries are shipped to the trade in the rough state or they are cut into finished articles by the producer. It is the practice of dressing companies to conduct this portion of their business in different mills, according to the use that is to be made of the finished product. Interior, exterior and monumental departments are recognized, but the operations differ in detail only.

The marble is first cut to the desired size by means of gang saws; if it is required to finish the sawn blocks or slabs with plane surfaces, they are moved next to the rubbing beds, where the surfaces are rendered quite flat. The final polishing is effected by treating the surface with abrasives of gradually increasing degrees of fineness. In hand polishing, five substances are successively employed, as follows: (1) coarse sandstone from Ohio; (2) blue grit from Nova Scotia; (3) red grit from Nova Scotia; (4) pumice; (5) hone.

Hones are of different kinds, the commonest being the Scotch hone or black hone; these are both fine grained shales. The final gloss is given by putty powder (oxide of zinc). Oxalic acid is also used if the marble is free from flint, and the time required to raise the gloss with putty powder is thereby much reduced. Oxalic acid cannot be employed with marble in which there are any hard streaks, as the corrosion

Turning a 45-ton block of Marble, Proctor, Vt.

or burning of the marble causes the harder material to stand out in relief. While hand polishing must still be employed for all marble objects of complicated design, it is superseded by the gritting and polishing machines for plane work.

Wm. Britnell, Sommerville, Victoria County

The stone quarries of Wm. Britnell, 1127½ Yonge Street, Toronto, occupy about 9 acres at Sommerville, Victoria County, Ontario. An extensive opening discloses successive beds of solid blue limestone, grey and red limestone, and shales, to a depth of about 15 feet.

About 34 in. of the upper layers consist of a light brownish grey stone, fine grained and almost lithographic in character. On the whole, it is a fairly uniform, compact and durable stone. Lower down occurs a 6-in. layer which is partly fine grained and lithographic, but it is so filled with calcite crystals that it presents a more irregular surface on weathering. It has, however, a rather more desirable color than the upper stone.

Near the lower part of the bed is a layer of hard, red limestone which, when polished, presents an extremely attractive appearance. These red stones are very hard and have been used for rougher purposes on account of the difficulty of chiselling, but present splendid possibilities as a valuable decorative material. Most of the product of this quarry is converted into crushed stone, but building stone is shipped from time to time. The quarry is equipped with derricks, steam drills, etc., besides a thoroughly up to date crushing plant.

Uniformity in building codes is a very desirable feature that has had a pronounced exploitation by the leading technical societies recently. The application of building codes, although practised for ages, is just beginning to be worked into intelligent shape.

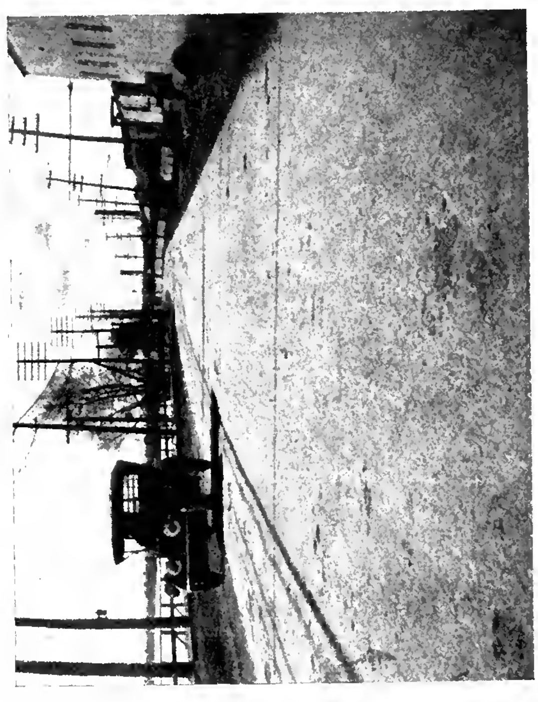
Miramichi Sandstone. Adam Hill's Quarry, near Newcastle, N. B.



Lake Shore Road where Ontario Trap Rock was used.

The Benching Method of Quarrying Rock

IN the bench method of quarrying the face is worked in one or a series of regular steps or benches, the height of the benches being governed by the thickness of the ledges and the location of the natural seams. Benches may vary from a few feet up to 20 feet or more in height but the most common run from 12 to 16 feet high.

In this method of working, percussion drills driven by steam or air and commonly called tripod drills, are usually employed. Tripod drills, up to about seven years ago, were in general use in quarries, but are now being rapidly displaced by the blast-hole cable drills where these are adapted. Tripod drilling and benching is best adapted where the face is not high enough to permit or where natural conditions exist which prevent the economical working of a well drill.

Occasionally even in quarries of high face where other conditions are favorable to use a well drill, the chemical content of the stone may vary so much, making it necessary to sort the material, that tripod drilling and short benching are compulsory. This may happen where stone is used for cement manufacture where it must be sorted to get the proper mix or in stone used for fluxing purposes.

In Tripod Drilling

In tripod drilling it is necessary to change steels or bits for every two feet of hole drilled. To facilitate drilling and prevent sticking it is customary to drop the gauge at least one-eighth of an inch for every change of steel. So that in drilling a 16-ft. hole, for instance, seven changes are made, and the finishing bit is seven-eighths of an inch less in diameter than the starting bit. We have then a tapered hole, smaller at the bottom than at the top. As a rule the bottoms are the hardest to pull, and from an explosive standpoint these holes are, we might say, upside down, and it is often impossible to concentrate enough explosive in the bottom to pull the bench cleanly. For this reason one often has to resort to springing or chambering, if the rock will stand it. If the ground will not stand springing often two or three divergent holes are drilled from one set up of the drill to permit more explosive being used. This, of course, greatly increases the drilling cost per ton of stone. Oftentimes a customer complains that an explosive is weak and does not pull bottom, when perhaps the trouble is that the holes are spaced too far apart or the finishing bit is too small. It is cheaper, as a rule, to spread the gauge of the drills than to jump from a forty per cent. to a sixty per cent. explosive to gain the same end. Take for example, a case where 16-ft. holes are drilled, starting bit 2 ins. in diameter. This means a 1⅛ in. finishing bit. Chances are 1¼ x 8 in. dynamite is used, and if so they do not get the powder to bottom of holes. Assuming they do, however, it is possible to get only about one pound of dynamite in the bottom two feet of hole. If the starting bit were increased to, say, 2¾ in., the finishing bit would be 1⅞ in. diameter, and about three pounds of dynamite could be loaded in the bottom two feet. It is evident, then, that this is a question deserving of consideration when selecting an explosive for a piece of work.

In spacing holes a great deal depends on the character of the material, direction of the strata and the purpose for which stone is used. If the stone lies flat a normal spacing for a 16-ft. hole is 8 ft. x 8 ft. in most material with unsprung holes. A 16-ft. hole should be loaded half its depth, at least, with explosive. If stone is pitching and is worked with the pitch the spacing may be increased. The heavier the pitch, the farther back the holes can be set. In a case like this it is usually only necessary to start the stone sliding to clear the bench. In experience it has been found best to use a quick and light explosive like extra or straight dynamite rather than a gelatin dynamite, because it is necessary to hit the stone as hard and as quickly as possible to insure maximum breakage before the sliding has commenced. Concentration is not desired, but distribution and a dense explosive would be found more expensive than a granular dynamite.

Working Against the Pitch

If the stone is worked against the pitch it is evident that the explosive has to lift the stone up and push it over the edge to clear the bench. In this case it may be necessary to spring the holes if possible, or space more closely or resort to divergent drilling. Also probably best results would be obtained by using a dense explosive like gelatin if holes were not sprung. The use to which a stone is put has an important bearing on the explosive question. If stone is used for lime burning it is not desired to break it up too much as spawls are usually wasted in quarries of this kind. Therefore, a slower explosive should be used, such as Red Cross ammonia. If stone is used for cement manufacture or crushed for commercial purposes a quicker explosive should be used or holes spaced so as to obtain maximum breakage in the initial shot. Except in very tough and hard material it will seldom be found necessary to use an explosive of greater strength than forty per cent. In some of the traps and granites a sixty per cent. explosive is necessary. In the bench method of working and tripod drilling a great item of cost is bench cleaning. In winter this is more expensive than in summer. Effort should be made to arrange the spacing of holes and select the proper explosive so that the bench can be cleared on the initial blast. It may be necessary to experiment for a while with different spacings and various explosives in order to arrive at the most economical method of obtaining this result. In most quarries where tripod drilling is practised, the stone is loaded by hand. If so, it is necessary to have as much of the stone one man size down in the initial blast as possible. In any case this is always desired, even if a steam shovel is used, as it means then maximum efficiency for the shovel.

Development of Lighter Drills

During the last few years there have been developed smaller, lighter drills of the "jack hammer" and "bull moose" types. These drills are self rotating, easily operated and hollow steel is used for bits. They work best with air but can be operated with steam power. They are very fast drills and 200 feet to 250 feet of hole per day can be made in straight continuous work. The jack hammer weighing less than fifty pounds is used mainly for block holing and secondary drilling but occasionally in bench work. The "bull moose" weighs about 90 pounds and is better adapted for heavier work. Only one man is required to operate either drill.

Grindstone Quarries of the Maritime Provinces

A number of quarries in New Brunswick and Nova Scotia are given over very largely to the manufacture of grindstones. The chief of these quarries is as follows: at Stonehaven, Gloucester County, N.B., owned by the Read Stone Company; the Micmac Grindstone Co., Limited, near Woodburn, N.S.; the Dorchester Stone Works, near Dorchester, N.B., and the Miramichi Quarry Co., Quarryville, N.B.—the latter quarry

The Grindstone Yard of the Read Stone Co., Stonehaven, N.B.

also produces a considerable quantity of building stone.

Of the above mentioned grindstone quarries, much the largest is that of the Read Stone Company. This quarry produces grindstones of every required size, varying from 8 in. in diameter and 1 in. to 2 in. thick, to 7 ft. in diameter x 14 in. thick. This latter size weighs approximately 3¼ tons. Probably the majority of the grindstones required in Canada are produced from the Stonehaven plant, and large numbers are exported to the eastern United States, and in smaller quantities to other countries.

This quarry has been controlled by the Read family for over one hundred years, the original owners being Joseph Read and John Seaman, who acquired control about 1815. The Read brothers now operating these plants at Stonehaven and Wood Point, are the great grandsons of the original owners. The Read Stone Company are at present testing out a new property at Quarryville.

The Dorchester Stone Works, the next most active grindstone quarry in Canada, began operations in 1908 and has been operating on a small scale since that date. They have a plant consisting of a 35 h.p. boiler, engine, 4 ton steam hoist, turning lathe, steam drill, derrick, etc. Axe and pulp grinding stones are both turned out. The property consists of over 1,000 acres. The stone has always been used to a considerable extent for foundations, but it is the intention of the company to cater to the pulp stone trade almost exclusively. This plant is well situated on the Petitcodiac River within easy reach of the shipping wharf. F. C. Palmer, of Dorchester, is president of the company.

Quarries of Pictou County, Nova Scotia

By R. E. Chambers

THE northern part of Pictou County is occupied by Carboniferous and Permian strata, dipping for the most part northwardly under the waters of the Gulf of St. Lawrence and Northumberland Strait. In the upper part of these formations are many beds of sandstones which in the past have produced large quantities of building stone and grindstones. The building stones were formerly, and the grindstones are now, exported to the United States, in addition to home consumption. Many of the buildings of Halifax have been constructed of this material. The district may be divided into three sections, viz.: Merigomish, Pictou Harbor, and River John.

Merigomish

It is at Merigomish that the greatest quantity of grindstones have been produced. On Quarry Island, in Merigomish harbor, is the quarry which has been most extensively worked. The grindstones produced have been of excellent quality and large size. The dip of the strata necessitating more pumping, this quarry has been worked on a small scale only during the last few years, but it is said by the owner that a moderate expenditure for pumping and other machinery would again put it on a large producing basis.

At the west end of Merigomish Harbor grindstones have been quarried on the mainland for several years. These are hauled to the Intercolonial Railway and shipped to the United States.

Pictou Harbor

At various points on Pictou Harbor freestones of good quality were quarried for many years. The earliest workings were at Sawmill Brook, about four miles from the town of Pictou. Here a shipping pier was constructed about a mile from the quarries. The stone is moderately hard, the color being gray of various shades. No work has been done at these quarries for many years.

About two miles from the town of Pictou and one mile from Pictou Harbor, is a quarry which has produced a large quantity of freestone. This was worked by the Pictou Quarries Company, but is not now operating. The stone is easily cut, being light gray in color and occurring in beds of considerable thickness.

The shipments were made by a siding connected with the Intercolonial Railway at Pictou, and by a wharf on Pictou Harbor. Shipments were formerly made to the United States, and more recently to the various towns in Nova Scotia. The Bank of Nova Scotia at New Glasgow, is constructed of this stone.

Some years ago the Granton quarry was opened at Granton, near the Middle River. The stone was used for railway construction on the Short Line and Pictou branches, then being constructed. They were also

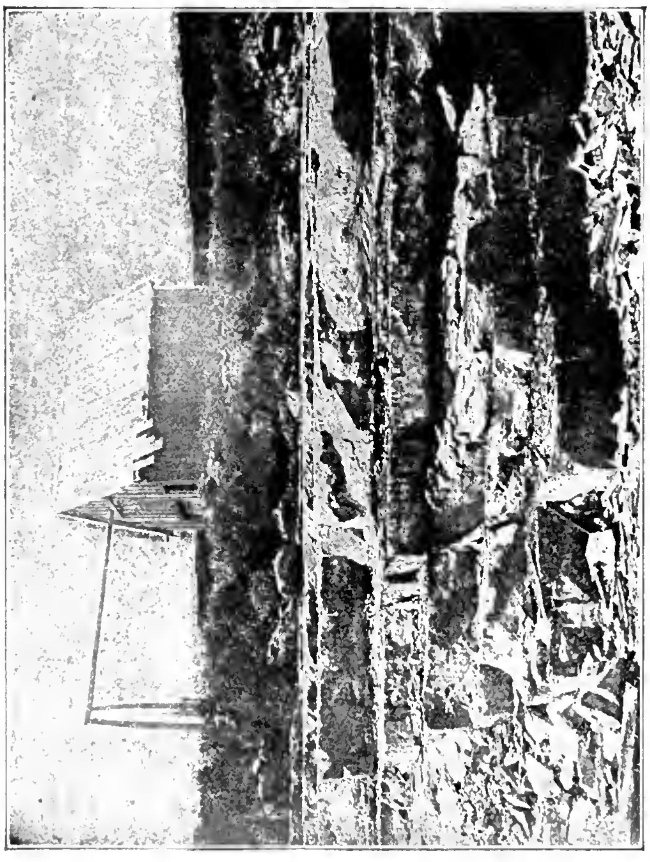
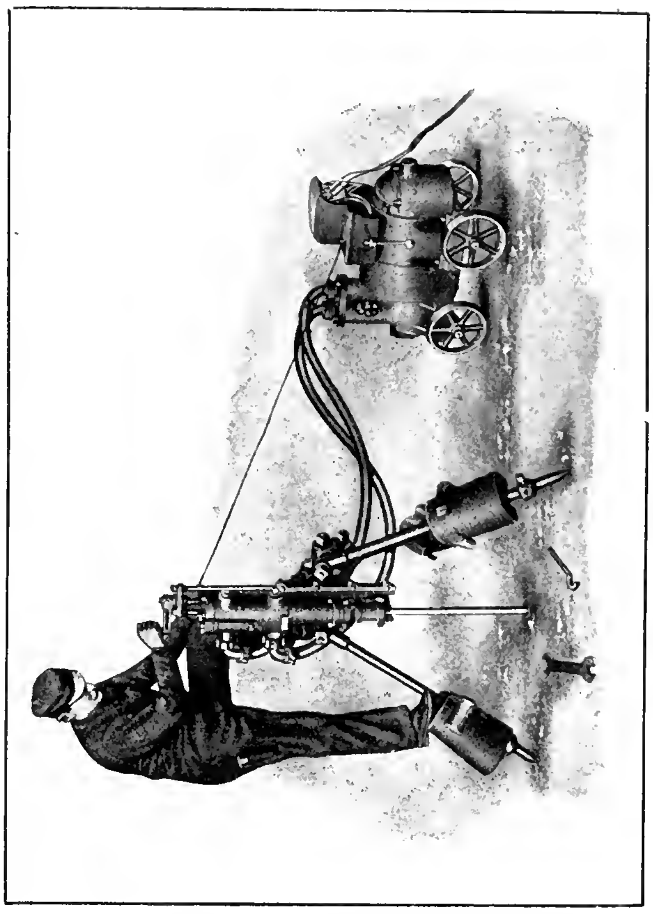
Queenston Limestone. Electric railway bridge over the intake, Canadian Power Co., Niagara Falls, Ont.



Level Upper Beds, Longford Quarries, Longford Mills, Ont.



Electric Air Rock Drill.

shipped to Halifax for building work, and grindstones were shipped to the New England States. The stone is light gray in color, easily cut, and free from iron stain. The grindstones produced were of excellent quality.

River John District

In the western part of the County the Permian strata contain some beds of fine grained red sandstone which have been rather extensively quarried. Near the village of River John shipments have been made from the Roger's Farm and from near the crossing of the river by the Intercolonial Railway, and on the Strait shore they have been worked on the Henderson farms. The stone is reddish brown in color, fine grained and easily cut. Considerable quantities have been shipped to Toronto for building purposes. They resemble in color the Credit Valley red sandstones, but are much softer in texture.

The stone in the New Glasgow post office and other buildings there are from this district.

Limestones

Underlying the true carboniferous strata of this county, which produces from many thick seams its large output of coal, there are extensive exposures of the Lower Carboniferous Marine Limestone formation containing beds of limestone of good quality.

The blast furnace of the Nova Scotia Steel & Coal Co. was formerly operated at Ferrona, and during this period extensive quarries of limestone were operated as Springville and at Black Rock, on the East River, for this furnace. The quality is fairly good, analysing about 93 per cent. in carbonates of lime and magnesia. In addition to these, quarries were opened on a small scale at various points for local purposes.

Trap Rock

An extensive quarry is operated at Black Rock, on the East River, by the Pictou County Contractors' Supply Co. Elaborate tests have shown this stone to be of exceptional hardness and durability, making it very desirable for road metal and for concrete purposes. The quarry is equipped with rock breaker, screens, bins, etc., and is extensively worked. Shipments are made over the Intercolonial Railway. The stone has been extensively used for street pavements in the town of New Glasgow, and for concrete structures at the many works located there.

Roger Miller & Co., who have the contract for constructing the Carleton Point end of the car ferry connecting the main land with Prince Edward Island, have a three years' lease of the quarry of E. A. Smith, Shediac, N.B. The quarry contains a freestone of a light olive shade, which is fine in texture, easily worked when green, and capable of taking the finest tool work. It becomes very hard when weathered, but splits beautifully, according to the owner of the plant. Stone from this quarry has been furnished for several buildings in the city of St. John and Fredericton, also for the Telegraph Building in the city of Quebec. The Miller lease expires with the present season.

The Thames Quarry Company, Limited, St. Marys, Ont., have just reopened their quarries for this season. Their principal product is crushed stone for roadmaking and concrete work, although they get out considerable building stone such as rubble and coursing stone, as well as some dressed stone. This company also manufacture pressed brick made from ground limestone and cement; these are cured in steam kilns.

Why We Use U. S. Stone

By a Cut Stone Contractor

The quarrying and stone cutting industry throughout the Dominion has made rapid progress in the last twenty years; this is especially true of the stone cutting section, but there still remains much to be done so far as the quarrying end is concerned. There are several reasons why Canada uses such quantities of imported stone. First, and principally, cost; second, architectural features desired by architect or client regarding color schemes; third, imported stones now in use are more adapted to machine work, thereby cheapening production; fourth, practically unlimited resources regarding supply and shipment of same.

Regarding the cost of rough quarry blocks, several items have to be considered, included the soundness of stone, the shape in which it comes from the quarry, and the time and quantity for delivery. The imported rough quarry blocks usually come squared up in excellent shape, ready for cutting up for the finished product, and the waste is reduced to a minimum thereby, whereas the usual Canadian quarries are handicapped in not having and using up to date quarrying apparatus. I am drawing attention to these points as the reasons for so much imported stone being used. The cut stone contractors have also to pay more for Canadian stone at the quarry than they do for United States stone at the quarry.

To improve conditions to meet the foreign competition—I refer now more especially to the Province of Quebec—additional capital is required to exploit the quarries. Larger sums will have to be spent in purchasing better machinery. In the United States the quarries are equipped with the most modern machines, enabling them to produce rough building blocks at a minimum cost, and to reduce their overhead charges by reason of the immense quantities shipped out. There is also this fact to be taken into account—more up to date equipment will mean that Canadian quarry owners will be able to produce stone in a far better condition for the cut stone contractors to handle, thus saving the large amount of waste at the finishing yards, which are usually located some distance from the quarries. I desire to lay emphasis on this point, as the waste is a very important factor in the price which the consumer has to pay.

In obtaining a better class of stone the cut stone contractor will save an appreciable amount in freight charges on rough quarry blocks. At the present time, owing to the condition in which the blocks leave the quarries, a considerable sum is unnecessarily spent in the freight of material which is absolutely worthless as building stone. The blocks have to be squared up, and the resulting waste on which freight has been paid cannot be disposed of to even cover the cost of that freight.

United States quarries will turn out stone exactly to our specifications, whereas we are not at all certain as to the sizes which will be supplied by many Canadian quarry owners.

As regards color, it is impossible to obtain in Canada many of the colors we require, and we are therefore bound to import from elsewhere.

The D. Robertson & Co., Ltd., Milton, Ont., quarry all kinds of Credit Valley grey sandstone, such as rubble, dimension blocks, coursing, sills, lintels, verandah caps, etc. They do all kinds of dressing at the quarry. This company also have lime kilns and burn what is known as Milton grey lime.

The Sackville Freestone Quarries, N.B.

The Most Important Producer in the Maritime Provinces—Operations Carried on with Most Modern Machinery and Business Methods

THE quarry of the Sackville Freestone Company, Ltd., which is located close to the town of Sackville, N.B., must be regarded as the most important producer of building stone in the Maritime Provinces. This property at Sackville was opened up a number of years ago by Mr. Charles Pickard on his farm, and later taken over by the Sackville Freestone Company, Limited, of which Mr. Pickard is manager.

The quarry is situated a short distance from the main line of the Intercolonial Railway, and covers about 50 acres of the company's property. The quarry proper is about 200 ft. square and 60 ft. deep. The upper 20 ft. is soil, beneath which is 40 ft. of red sandstone in beds up to 5 ft. thick. The various layers are horizontal and are remarkably continuous, with scarcely any of the lenticular bedding so common in the sandstone quarries of the Maritime Provinces. The isolated formation of the rock deposit is unique in the respect that it is entirely local and

Blocks of Sackville Freestone—See other pages for further illustrations of this Quarry.

altogether different from the other deposits in the country, being very even in color and quality and of a much finer grain than the surrounding stones, which are coarse, uneven and soft, for the most part.

The rock probably belongs to the Permo-Carboniferous age and presents a subdued red appearance in color. Under corrosion there is little, if any, change in color and but a slight loss in weight. The quartz grains are for the most part sharply angular and of a variable size. Feldspar and mica flakes are scattered through the rock.

The following are the principal physical characteristics of the stone: specific gravity, 2.711; weight per cubic foot, 145.743 lbs.; pore space, 13.882 per cent.; transverse strength, 1,016 lbs.; crushing strength, 11,889 lbs.

The red Sackville stone is used largely throughout the eastern part of the Dominion, and, notwithstanding the freight charges, is able to compete successfully with other stones for buildings of the best type in Ontario.

Among the many structures in which the Sackville stone has been used, the following may be mentioned: Royal Bank, Sackville; Bank of Montreal, Moncton, N.B.; Observatory, Ottawa; new wing of Parliament Buildings, Toronto, etc.

While the Sackville Freestone Company have an asset in this stone, which has undoubtedly been proven one of the best of the kind in the country, it is not on this alone that the success of the company depends. The up-to-date methods of handling the stone in the quarry, and the business-like way in which the industry has been conducted, have also been important factors. The company have installed an up-to-date plant and are planning for further extension of the facilities already provided. The equipment may be summarized as follows:—

Four 20 ton derricks, operated by one large engine and boiler, and one small engine and boiler; two steam drills; two Patch gang saws, operated by electricity, which is also used for one of the derricks; a steam shovel for handling overburden, and a 15 ton Brown hoist locomotive crane. The mill is placed close to the quarry and is so arranged that a minimum of handling is necessary. A spur branch about 1½ miles long from the Tormentine branch of the Intercolonial Railway affords good shipping facilities. About 25 men are employed by the company.

The total output of the quarry is from 8,000 to 10,000 per annum, all of which is used for building stone. As indicative of the favor with which this stone is being received in Ontario, it is worthy of note than it is enjoying an increasing sale in Hamilton, London, St. Thomas, Chatham, and many other towns in Western Ontario.

The firm has a reputation among contractors of being business-like in every sense of the word. No work is undertaken that cannot be completed, and contractors are not delayed by the tardy execution of orders.

Armstrong-Whitworth Extensions

John Quinlan and Company, Westmount, P.Q., have obtained a contract for doubling the plant, at Longueuil, of Armstrong Whitworth of Canada, Limited, of which Mr. M. J. Butler, C.M.G., is managing director. The floor space will be increased from 50,000 to 100,000 square feet, and a new structure and office building will also be erected. The new plant of steel and concrete, includes units for the manufacture of steel tires for locomotives and passenger rolling stock, the rolling of steel wheels, and the manufacture of forged axles. A rolling mill will be installed, and provision made for making special rounds and shapes for electric smelted steel. The contract for the steel work of the extension has been let to the Dominion Bridge Company. The total cost will be about $750,000.

An Up-to-date Stone Crushing Plant

The buildings of Crushed Stone Limited are new and the equipment powerful and modern — A rapidly developed business

ONE of the most modern crushed stone plants, and one of the largest, though possibly not the largest in Canada, is that of Crushed Stone, Limited, of Kirkfield, Ont. At the present time this company is opening a new quarry close to the Trent Valley Canal and in the immediate vicinity of their new crushing plant, built in 1914, as illustrated in one of our accompanying photographs. This quarry is being opened up to an 18 ft. surface. One of the illustrations also shows a new steam shovel just installed by this company, a hundred ton Bucyrus, equipped with a five-yard capacity dipper. This shovel will dig 2,500 tons of stone per day and is thus easily the equivalent of 100 men. It is one of the largest, if not the largest, at present operating in the Dominion. An auxiliary shovel of 1,500 tons' capacity, is also in use by the company.

Plant of Crushed Stone Co., Ltd., Kirkfield, Ont.

Particular interest centres round the operation of the crushing plant. Fig. 1 illustrates the various phases of the necessary operations. That part of the building marked "A," contains the crusher. The stone coming from the quarry is shunted on the track, shown in the right hand side of the picture, by a donkey engine, and drawn up the incline by a steam operated cable. The stone is here dumped into the crusher and the car returns by gravity to the level surface. A loaded and empty car are seen in the picture, one ready to ascend, the other just returned from the crusher shed. Two crushers are installed, a No. 7½ and a No. 5, so that the capacity of the plant is approximately 1,000 tons per ten-hour day.

From this point the crushed stone is elevated into "B," thence passes to "C" for screening, and, by gravity, to graded bins in "D," from which it is loaded, also by gravity, into railway cars, which pass beneath "D, and one of which may be seen in the picture.

15 Ton Locomotive Crane.

The gradations in the screening house have been carefully adjusted and at least seven grades of stone are always available. These are what is known as stone dust, grit, ⅜ in., ¾ in., 1¼ in., 2 in., and approximately 4 in. Grit is becoming increasingly useful in making country roads, where it is valuable for filling up the interstices between the larger pieces of stone. It is also used to a considerable extent in the manufacture of cement block.

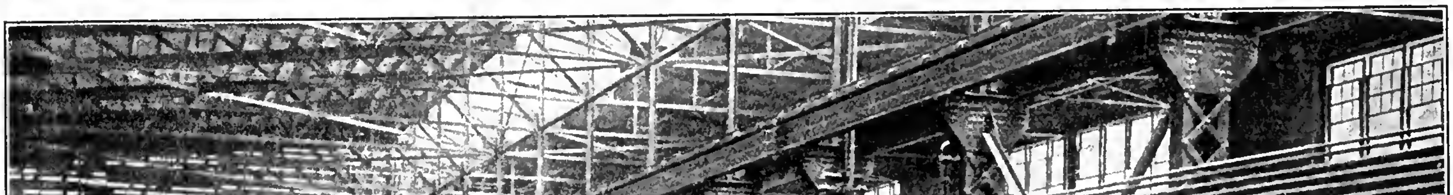
Any surplus supply of grit is carried back in this plant to the building marked "E," where it is ground into fine flour dust and finally deposited in 100-lb. bags. This dust is now used very largely in the coating surface of asphalt pavements.

A useful part of the equipment of this company is a 15-ton, 8-wheeler, locomotive crane, link-belt type, with 50 ft. boom. It frequently happens that one or other size of crushed stone is in excess and the company finds it necessary to take these out of the storage building, D, and place in piles beside the railway siding, where 10,000 tons can be piled. For unloading and loading purposes this crane is used.

5 yd. Bucyrus Steam Shovel.

Another interesting feature which indicates the modern equipment of this company, is the use of a 5-in. well drill, which is used for drilling the 18 ft. face of the quarry. This type of drill, we understand,

Miramichi sandstone. Quarry of the Miramichi Quarry Co., Quarryville, N. B.



Stanstead granite. Interior of the Stanstead Granite Co's mill, Beebe Plain, Que.

is replacing other drills at the present time on account of its much greater capacity both for quantity and depth.

The Kirkfield quarries of Crushed Stone, Limited, are, at present showing, almost unlimited in extent. The initial working will be about 600 feet in length with, as already intimated, an 18 ft. face. No stone is quarried for any purpose other than crushed stone. Mr. W. H. Essery is in charge of the operations at the quarry, while Mr. G. W. Essery, his son, attends to all the general business and sales at the Toronto office, 47 Yonge St. Arcade. To the energy and fine executive ability of these men the success of Crushed Stone, Limited, is entirely due. This success is indicated by the fact that the business has grown in a short time from 20,000 tons per year to over 100,000 tons per year.

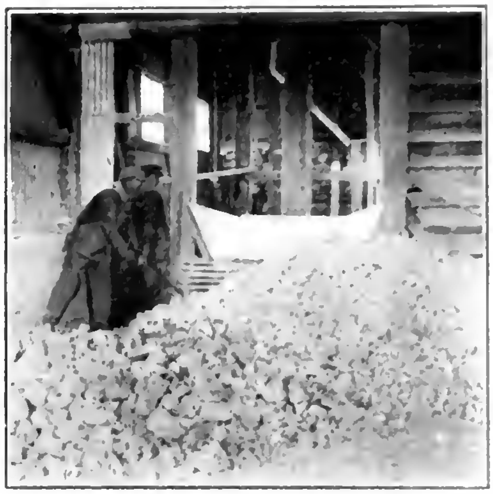
Alabaster Hydrated Lime

Alabaster Hydrated Lime is lime of great purity and strength, which has been slaked or hydrated at the kilns by adding to the fresh burned lime just the right amount of water. It is carefully and scientifically handled, packed in 40 lb. bags, in fine, dry powder form, water slaked and ready for use.

The limestone, which is a Dolomite lime, is blasted out of the solid ledge in the quarry and broken up into the proper size for burning. It is then taken to the kilns and burnt. This process is a continuous one—rock put in at the top and burnt lump lime taken out below. The burning is done to drive off the carbon dioxide and any moisture in the rock. A limestone weighing 100 lbs., put in at the top, weighs approximately 56 lbs. when it is taken out at the bottom.

View of Lime Kilns and Hydrating Plant. Two more kilns under construction.

The freshly burned lime, after being drawn out of the kiln, is allowed to cool and then shovelled into the hopper of a large rotary crusher, which crushes the lime down to ¼ in., or smaller size. After passing through the crusher the pulverized lime is elevated to a storage bin, fed from there into a weighing hopper, and from the hopper into the hydrator, a large revolving pan with stationary plows which turn the lime over as the pan revolves. The proper amount of water is added and as slaking takes place, heat is generated and a chemical action occurs, which, when just the right proportion of water is used, produces commercial hydrated lime. The hydrated lime, having taken all the water it will absorb, will consequently absorb no more moisture from the air, as the free lime has all been slaked, whereas air slaked lime has slowly absorbed moisture and also carbon dioxide from the air and has thereby lost part of its cementitious qualities. After passing the hydrator, the lime is ground



Supply of freshly burned lime.—Alabastine Co., Paris, Ont.

to a very fine powder and automatically bagged in 40-lb. paper sacks.

Besides its major importance as a finish plaster, hydrated lime has several other minor uses—for waterproofing concrete, for agricultural purposes, for paper making, glass making, alkalies, fertilizers, lubricants.

The head office of The Alabastine Co. is in Paris, Ont. The rock deposits and hydrating plant are located at Elora. The same company operate a gypsum mine and mill at Caledonia, Ont.

St. Laurent Quarry Ltd.

The St. Laurent Quarry Ltd., Cap St. Martin, Que., operate a modern crushing plant at that point. The nature of production is crushed stone of hard limestone in all sizes from 3 in. to ¼ in. screened, also limestone dust. This latter, by Government analysis, is found to contain 87½ per cent. of pure lime, and is thus a valuable aliment used largely for fertilizing.

The company's crushed stone has been in great demand by the surrounding municipalities for the construction of macadam and concrete roads, and especially for the Montreal and Quebec Highway. The crushing plant consists of different sizes of crushers, with a total daily capacity of 800 tons. It is situated at Cap St. Martin, Que., Laval County, close to St. Martin Junction, which is a junction point between Ottawa and Quebec, on the C. P. R., a short distance from the city of Montreal. The head office is at the plant.

The office staff of the company consists of Mr. Francois Dufresne, St. Laurent, Que., well known as general contractor, having to his credit the erection of many large buildings, as, for example, the Windsor Station Annex, C.P.R., Montreal; the Good Shepherd Building, Laval des Rapides, Que.; the manager, Mr. Charles Le Pailleur, St. Laurent, Que., who has been engaged in the business for the last ten years; the secretary, Mr. J. A. Poulin, Cap St. Martin, Que.

Credit Valley an Architects' Favorite

Lends Itself to Artistic Design—Shown at its Best in Ontario's Schools, Colleges, Churches and Handsomest Dwellings

A CONSIDERABLE part of the grey sandstone used in Toronto in recent years in the construction of public buildings, has been obtained from what is known as the Credit Valley area in and around Glen Williams, which is only a few miles from Georgetown, and about 30 miles from the city of Toronto.

One of the principal owners and most extensive operators in this section is the firm of F. Rogers & Co., 1193 Queen Street West, Toronto. The company own outright two of the biggest quarry properties there, and another very extensive one is worked in conjunction with Mr. Hugh Logan, of Glen Williams. Here can be found some of the finest grey Medina sandstone which makes one of the best building stones at present produced from the sedimentary rocks of Ontario. The coloring of the stone is practically perfect. Beneath the capping of debris in the quarry lie about five feet of thin, shaley limestone, from which only a little rubble is procured. Then follows 14 feet of sandstone, of which the upper 7 feet is excellent grey freestone of varying thicknesses, the lower seven feet being one solid bed of beautiful blue-grey color. In some places a single bed occupies the whole of the 7 feet.

A practically unlimited supply of the largest blocks is to be found all over the quarries. Railway switches are laid right into the quarries and all modern equipment for the handling of the largest orders in the shortest possible time. Heretofore the company have not sawn the stone themselves, but modern stone-sawing equipment in the nature of several gang saws, is now being placed in the Logan quarries, which will enable them to deliver orders sawn to specifications. From time to time further equipment along the line of planers and lathes will be installed, so that every class of finished stone work can be supplied in Canada from a Canadian quarry.

Some of the largest and most representative public buildings and residences in Toronto have, within the last few years, been built with the stone supplied by F. Rogers and Company from these quarries. Among these we might mention, Toronto Technical School, Knox College, Bishop Strachan School, Victoria Library, Burwash Hall, Yonge Street Methodist Church, Rosedale Congregational Church, the Pellatt residence, the Hart House, Queen's Park; Hon. A. E. Kemp's residence, Mr. Gurney's residence, Spadina Road; Metropolitan Methodist parsonage.

In addition to these quarries, the Oliver, Rogers Crushed Stone Company, Limited, of Owen Sound, is, in conjunction with Mr. Oliver, of that town, owned and operated by the same company. This is a most modern crushed stone quarry with a daily capacity of 500 tons and a full equipment comprising 2 crushers, elevator, steam shovels, and shipping facilities from three sidings into the yards.

Preparedness

Is your machinery in good order? And have you sufficient labor in sight for the coming season? Preparedness in the plant is a big factor in increasing your business and producing profits. The company that is willing to handle all classes of work the quarry is capable of, is, other things being equal, the one that will make good profits. With building increasing, better opportunities for cut stone men are constantly presenting themselves. Watch the opportunities and see that substitutes are not allowed to slip in ahead of you—no matter whether the contracts are great or small. Watch for every class of work. Emphasize the lasting qualities of stone, its solidarity and beauty. These qualities, with a preparedness for bigger volume of business, will be the prime factors leading to success in the Canadian stone trade.

In the case of certain stones, particularly sandstones, the process of seasoning adds greatly to the hardness. In such cases it is the practice to carve the stone before the quarry water has evaporated, and then to hold the product out of the wall until the seasoning is complete.

Knox College, Toronto—One of Canada's most beautiful buildings Credit Valley Stone.

Longford Quarry Co., Longford Mills

One of the best known Ontario quarries is that of the Longford Quarry Co., Ltd., situated at Longford Mills, a station on the Northern Division of the Grand Trunk Railway, 93 miles north of Toronto. The quarries comprise the easterly portions of Lots Gore "A," 21, 22, 23, 24, 26, and 27, Front Range, Township of Rama, Ontario County. The stone is a hard, fine-grained limestone, lying in beds varying from 4 in. to 16 in. in thickness. In color it is a very light grey, which tends to whiten with age. It is almost impervious to water and as a consequence does not soil or become discolored after being built in. The following are copies of tests as made by the Department of Public Works of Canada:—

Sample No. 1—Area exposed to crushing, 2.9 in. x 3.0 in. = 8.7 sq. in.; height of sample, 3 in.; ultimate crushing load, 181,000 pounds; crushing strength, per sq. inch, 20,805 pounds.

Sample No. 2—Area exposed to crushing, 3.4 in. x 3.4 in. = 11.56 sq. inches; height of sample, 3 in.; ultimate crushing load, above 200,000 pounds. (Note.—The strength of No. 2 was beyond the capacity of the machine, 200,000 lbs.)

Immense quantities of this stone were used by the Canada Iron Corporation, Limited, prior to their close-down in August, 1913, and we understand they found it most satisfactory for this purpose after a number of tests. As a broken stone for roads it is first-class material, as the roads adjacent to the quarries, where it has been used for a number of years, bear witness. Under traffic, it breaks up into fine particles which cement together, forming a good surface. Mixed with a proper proportion of broken granite, it makes an almost ideal road material. As a foundation stone it has gone into many of the large buildings of the country, among others the Temple Building, the Union Station, the Eaton Building, and several others in Toronto. The Toronto, Hamilton & Buffalo Railway tunnel at Hamilton, and the railway subways at King and Queen Streets West, Toronto, are built of it. It is, however, as a dressed stone for the better class of buildings of all kinds that its readiest market is found. In public buildings of all kinds it has been used to a great extent, notably in the post offices at Tilbury, Seaforth, Hanover, Aurora, Midland, Orillia, Port Perry, Lindsay, Bracebridge, and North Bay, in the drill halls at Peterboro, Oshawa, Lindsay, Barrie, and Orillia; in Roman Catholic churches at North Bay, Midland, Chelmsford, Orillia, and Peterboro (which are entirely of stone), and as trimming in a great number of other churches throughout the country. Among residences into which it has been built are those of Sir William Mackenzie, Avenue Road, Toronto; Frederick Mercer, Moore Park, Toronto, and J. B. Tudhope, Orillia.

The quarry is at present using a steam driven air compressor to run the rock drills and stone cutters' tools, and horses for thirteen derricks. The company hope, however, to get electric power in the near future.

Church of Angel's Guardian, Orillia—Constructed of Limestone from Longford Quarries

York Sand & Gravel Co.'s Operations

An Industry of Big Proportions that has Grown Rapidly—Company's Products in Increasing Demand

CANADA is a country rich in undeveloped possibilities, no only as regards her great northern and western stretches, but even in older portions. Right at the very borders of one of our greatest cities for years there have existed undreamed-of possibilities awaiting the discerning eye and the enterprising spirit of the pioneer to discover and develop. Such a possibility existed for years in the form of rich deposits of sand and gravel of the highest quality for construction work at the very door of a great market for such products, the city of Toronto, until the keen, discerning eye of a few of Toronto's shrewdest business men recognized the possibilities that lay there undeveloped. The result of this discovery was the formation of the York Sand & Gravel Co., Ltd., for the purpose of placing on the market this material, which became so popular that this company has grown to be not only the largest producers and dealers in sand and gravel in Toronto, but also one of the largest concerns of its kind in the Dominion.

The situation is ideal, comprising some fifty acres of land, rich in sand and gravel, in the township of Scarboro, in close proximity to Toronto, a portion of the property actually lying within the city limits. Being within the Toronto terminals of the Grand Trunk Railway, quick delivery at lowest possible cost can be given to any railway siding on the G. T. R. or connecting systems, in Toronto or its vicinity; also, if required, by motor truck or wagon delivery. The plant, which is of an elaborate and extensive character, has a present productive capacity of two thousand cubic yards per day, and an additional screening and washing plant is being installed, which will be the first of its kind in operation in Canada for commercial purposes; this will still further increase the productive capacity of the plant. To supply material of a special grade required in connection with the million dollar Filtration Plant constructed by the city of Toronto, special equipment has been installed on the company's property, which is something entirely new and an eye-opener to users of sand.

No order is too small to receive the most careful and courteous consideration, and no order is too large to meet with the prompt and efficient service which is characteristic of this company. It is only necessary to mention a few of the contracts of the company to prove the character of their products and their ability to give prompt delivery in large quantities. For example, "York sand" and "York gravel" were the materials used in the construction of such examples of concrete construction as the great Bloor Street Viaduct, the new Union Station, the two latest Toronto skyscrapers, namely, the Royal Bank and Dominion Bank buildings, and it is being used now in the big Robert Simpson Factory, the Eaton Factory, and the new Imperial Oil Co. building, all at present under construction. Large quantities of material have also been supplied to the Toronto-Hamilton Highway Commission, and during the present year this company is the holder of the city of Toronto's contract for supplying the corporation's requirements of sand and gravel for all purposes.

To any person interested in the development of our

General view, showing one phase of York Sand & Gravel Company's operations.

country's industry, a visit to the plant of the York Sand and Gravel Co., Ltd., will prove of interest; especially to those of our readers who are interested in the great development that has and is taking place in concrete construction, a visit will prove of educational value, and to many, doubtless, a source of profit, as well, when they come to figure on contracts. Interested visitors are always welcome, and the president of the company, Mr. T. J. Smyth, is always glad to show them over the plant and explain the same to them.

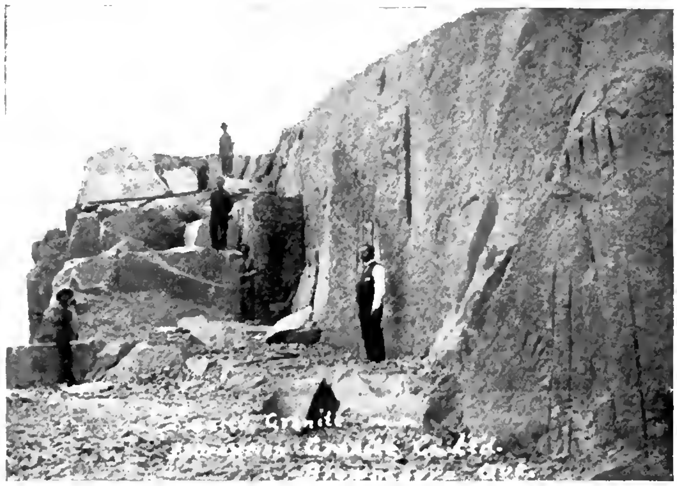
Street & O'Brien, Gananoque, Ont.

The firm of Street & O'Brien commenced work in their quarries in Gananoque in 1906. The stone is a very good quality of granite, colors red and dark blue, and an excellent stone for building and monumental work. This firm have also supplied the cities of Toronto, Montreal, and Hamilton with granite paving blocks. The stone lies in sheets from two feet and up to ten feet deep, and is a good solid stone, without seams or cracks.

Laurentian Granite Quarries

The quarries of the Laurentian Granite Company, Limited, 224 St. James Street, Montreal, are situated in the Township of Chatham, in the County of Argenteuil, P.Q., and are connected by a spur about 5 miles in length, with the Canadian Pacific Railway at Staynerville, P.Q. They cover an area of about 150 acres. The product is a medium to coarse grained granite of a pinkish to light chocolate color, crushing strength, 37,590 lbs. per sq. inch.

The equipment consists of hoisting engines, air compressors, pneumatic and steam drills, large crushing plant with a capacity of 500 tons per day, locomotive crane, completely equipped stone cutting shed,

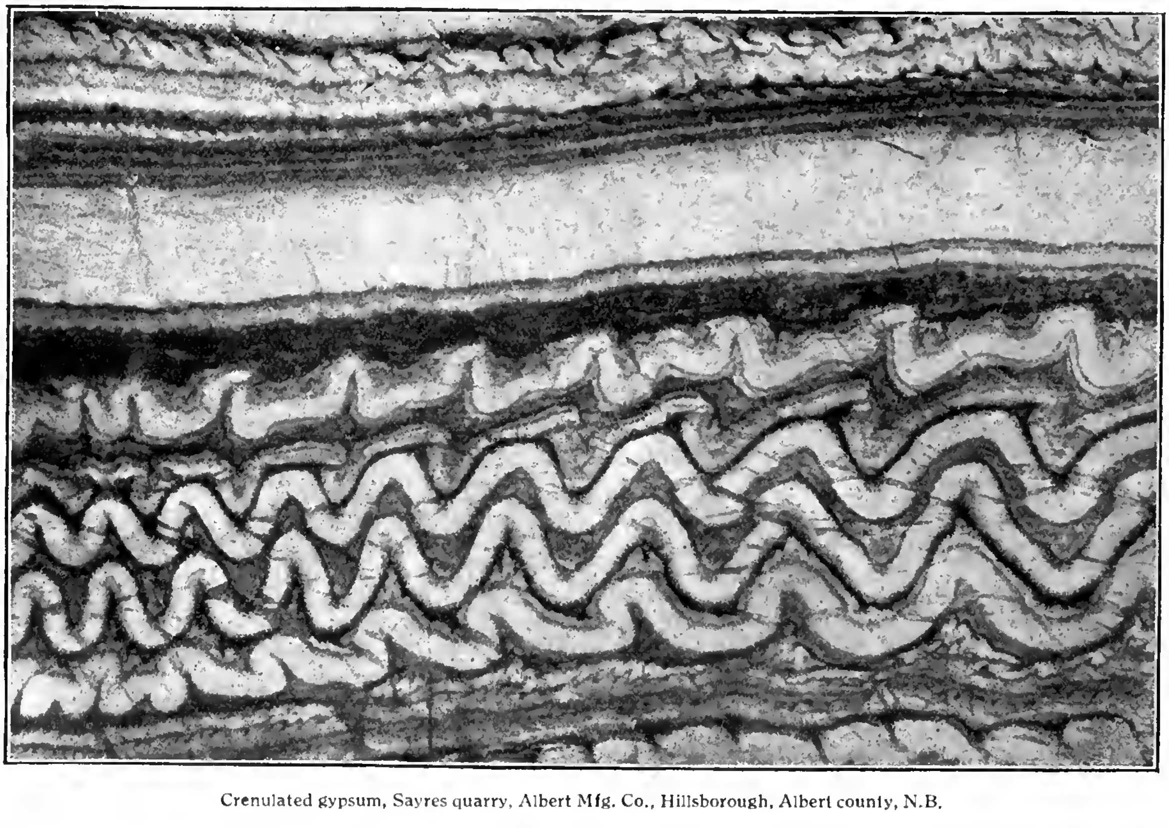


Solid granite quarry of Laurentian Company.

150 ft. x 60 ft. This company can execute any work in the granite line: building stone, curbing, paving blocks, crushed granite, etc., etc.

Laurentian granite has been used in the following structures: Montreal Jail at Bordeaux, Court House at Sherbrooke, Bank of Hochelaga at Three Rivers, Post Office at Hochelaga, University of Alberta at Edmonton, and many other important buildings. Work was resumed this year early in April, after a suspension during the winter months.

At the request of the Westmount Council, the Province of Quebec Association of Architects nominated the following four members to sit on the Westmount Commission which will pass on plans of new buildings:—Messrs. John S. Archibald, Robert Findlay, D. H. MacFarlane, and D. Norman McVicar. All four are citizens of Westmount.



Crenulated gypsum, Sayres quarry, Albert Mfg. Co., Hillsborough, Albert county, N.B.

Quarries in Central and Western Canada

Deposits at Tyndall, near Winnipeg, one of our Largest—Sechelt Quarries on the Coast Yielding a Fine Granite

THE granite quarries operated by the Sechelt Granite Quarries, Limited, are located about 65 miles up the coast from Vancouver, on Hardy Island. This quarry was opened up for the purpose of supplying the large granite blocks required in the construction of the Victoria Harbor breakwater, which is now being built by the Sir John Jackson (Canada) Limited, under a contract with the Dominion Government. The specifications for this work called for rectangular granite blocks weighing from eight to twenty tons each, and the quantity required to complete the contract will be from sixty to seventy thousand cubic yards.

The work of installing the plant was commenced in November, 1913, and the first stone was delivered in March, 1914. As the entire quantity was required to be delivered in less than three years, it was necessary to increase the original plant from time to time as the work progressed, so that the output has been brought up to 100,000 to 120,000 cubic feet per month.

The plant consists of six large derricks and steam hoists, each capable of lifting thirty tons, with masts ninety and one hundred feet high, and booms with a radius of about one hundred feet. Pneumatic drills are used throughout, the air being delivered by four compressors, one of which is belt driven, the power being furnished by a 50 h.p. internal combustion engine; the other three are steam driven from a central steam plant.

The quarry was opened up towards the top of a bluff about 150 feet high, and the blocks lowered to the water's edge by means of a gravity railway about 900 feet long. As the loaded car descends the empty car goes up, both being connected by a cable which passes over a snubbing device at the top, which controls the speed of the cars. Arriving at the water's edge, the blocks are lifted onto scows and thence towed to the harbor works at Victoria.

The magnitude of the work has required the installation of the largest and most up-to-date plant of its kind on the Pacific Coast, with a capacity exceeding any other quarry in the West. Frequently blocks of granite containing upwards of 50,000 cu. ft. are blown clear of the bluff by the use of powder, so that easy quarrying can be done.

Over 100 men are employed. Two tugs and five scows are constantly engaged in the work of transporting the output to Victoria.

The quarry is situated in a good harbor on Blind Bay, with deep water and the best of shipping facilities.

The Quarry Company are in the market for the supply of granite to any location for buildings, and the granite is a very good quality. Blocks of granite any size can be secured.

It is remarkable with what accuracy the stone cleaves. Plugs and "feathers" are used for reducing large blocks to the required sizes, and stones any length and 15 feet wide can be split perfectly true in this manner.

Tyndall Quarry Co.

One of the largest quarries in Canada is owned by the Tyndall Quarry Co., Ltd. The quarry is situated at Tyndall, Man., thirty miles east of Winnipeg, and consists of a very fine limestone which is economical

Sechelt Granite Quarries, Hardy Island, B.C.—Splendid Quarrying and Shipping Location.

to manufacture and rich in appearance. The quarry at the present time is equipped to supply cut stone, rubble and lime.

The plant consists of Sullivan and Ingersoll Rand channelers of the latest and heaviest make, to withstand the heavy work which they are subjected to; also a derrick of twenty tons capacity. Owing to the quarry being situated one and one-half miles from the C.P.R. main line, a 22-ton locomotive is utilized to switch the cars in and out of the quarry. The company are interested in four of the best stone cutting mills in Winnipeg, equipped with the most modern machinery that money can purchase.

The stone is being used in all the principal cities and towns throughout the Middle West as far as Calgary and Edmonton and east through Ontario. In Winnipeg, it is used in the new law courts, the Parliament Buildings, the agricultural buildings, and numerous warehouses and residences.

The Wallace Quarries

Sandstone for building purposes is found in many sections of the Maritime Provinces, the most important quarries being in Northumberland and Westmoreland counties, New Brunswick, and in Cumberland county, Nova Scotia. The famous Wallace Quarries are situated in the latter county and have been operated over one hundred years, being one of the largest and best equipped in Canada. Stone has been supplied from these quarries for many of the largest buildings in the Maritime Provinces, including the Parliament Buildings in Halifax, commenced in 1811 and completed in 1815.

During the last half of the last century stone from these provinces was extensively used in Boston, New York, Philadelphia, Baltimore, and other United States cities, but owing to an excessive duty being imposed by the United States Government, these quarries were compelled to abandon those markets and seek a market in Canadian cities, where they meet strong competition from United States stone which is admitted into Canada under a considerably lower tariff than the United States imposes on Canadian stone.

Among the notable buildings erected with Wallace stone in Canada are the Victoria Museum and Custom House, Ottawa, also the Custom House in Montreal.

Last season 42,500 tons of rough stone were supplied the Roger Miller Company, Carleton Point, Prince Edward Island, for car ferry terminals. Owing to war conditions the demand for stone is limited, but when peace is declared the Wallace Sandstone Quarries Co. state they are looking for a brisk trade in building stone.

The Wallace Sandstone Quarries operate also a large plant at Lyall, Manitoba. This plant is one of the largest in the Dominion, and coming to be one of the best known. The stone used in the new station recently built by the C.P.R. and the C.N.R., in North Toronto, on Yonge Street, was supplied by the Wallace Sandstone Quarries Company from their Lyall deposits. This stone is sometimes known as Tyndall stone on account of the close proximity of the two towns, Lyall and Tyndall, which are only about a mile apart. The three illustrations on this page will give some conception of the operations of this quarry.

Wallace Sandstone Quarries Co., Ltd., operations, Lyall, Man.

Two additions, 20 ft. by 100 ft. and 40 ft. by 80 ft., are being made to the plant of the Dominion Sheet Metal Company, manufacturers of "Premier" galvanized sheets, Hamilton, Ont. This company is sparing no efforts to give Canadian buyers of galvanized sheets a steady supply at this time, when import shipments are negligible. This has only been accomplished by high pressure work on the part of a thoroughly experienced staff and by having largely provided in advance against present extraordinary conditions.

Wallace Sandstone Quarries Co. operations, Lyall, Man.

Interior of Lyall Mill, Wallace Sandstone Quarries Co.

Masson Quarry, Montreal

The Masson quarry, located on a ridge of rock to the north of the C.P.R. Angus shops, Montreal, is operated by O. Martineau & Fils, trading as the Morrison Quarry Company, the selling agents of which are T. A. Morrison & Co., 204 St. James Street, Montreal. The great feature of the plant for producing crushed stone is the employment of electrical driven derricks, further described in another portion of this article.

The rock is of igneous formation, and is locally known as "Banc Rouge" Trap Rock. A recent analysis made by the Milton Hersey Co., Ltd., gives the following mineral analysis:—

T. A. Morrison & Company's crushing plant. Cut of quarry shown on page 569

Nephelite (Silicate of alumina, soda, and potash)	52.0%
Orthoclase (Silicate of alumina, and potash) ...	17.8%
Acmite (Silicate of iron and soda)	12.8%
Kaolin (Hydrous silicate of alumina)	17.4%
Specific Gravity	2.50%
Weight per cubic foot	156 pounds

This rock is particularly good for road work; it is very hard and tough, and has high wearing qualities.

The plant is very complete and produces crushed stone of the various sizes required for road building and concrete work. It is operated as two complete units. In the cut of the general view of the plant, on the right side is shown one unit consisting of four Champion No. 5 crushers, which reduce the stone to 2½ in. This stone is elevated from the quarry and passed through long screens which select the various sizes into separate chambers in the large hopper. The rejections come back and are reduced to ¾ in. by two 24-in. Simond disc crushers.

The plant is arranged to avoid hand labor. Two five-ton Pollard electric horizontal beam derricks hoist the stone direct from the quarry and dump it on the platform, which feeds through a hopper into the No. 5 crushers.

The second unit comprises a No. 5 Austin Gyratory Crusher, fed by two Anderson electric beam derricks. The stone passes through the Austin crusher, is elevated, and all the stone 2 in. and under is screened and deposited in the various chambers. The rejections are then passed through a 48-in. Simond disc crusher, screened as above, and the rejections again pass through a 24 in. disc crusher, reducing the stone to ¾ in. and under.

The most interesting features of the plant are the beam derricks, two supplied by the Geo. Anderson Company of Canada, Limited, Montreal, and two by the Pollard Manufacturing Company, Niagara Falls, Ont. They are the first of the kind installed in Canada, and greatly facilitate the work of transporting the stone from the quarry to the plant, each having a radius of 45 feet. The derricks have three distinct motions—hoisting, travelling along the beam, and swinging. Each derrick is operated by individual electric motors.

In drilling the rock, well drills are employed; these make a hole 3½ to 4 in. in diameter and 40 feet deep, that is, nearly to the bottom of the top formation of the rock. The holes are sprung, and then heavily charged, breaking up the rock to convenient sizes for sledging.

The rock is only suitable for crushing purposes, being of such a nature that it does not lend itself to hand cutting for building.

Famous "Queenston Blue"

One of the largest quarry operations in Canada is to be found in the Niagara district, where the Queenston Quarry Co., Ltd., produce the well-known "Queenston Blue" Limestone.

The stone is dolomitic in nature, containing granular crystals and small fossil organisms. The color is a beautiful bluish grey, which changes very little through the lapse of time and withstands atmospheric conditions to a remarkable degree, keeping a sharp clean face for a considerable period.

The extent of operations may be gauged from the fact that over twelve acres of this stone have been quarried to depths running from twelve to thirty feet.

General view of Queenston Company's quarry at St. David's, June 1, 1916.

The present plant consists of seven derricks of from ten to twenty ton capacity, compressed air plant, and large stone sawing mill, giving a quarrying capacity of about 200,000 cubic feet of stone per season; also a stone crushing plant of eight cars per day capacity.

This stone is used for all classes of construction and building operations, from residential foundations to the modern skyscraper, canal construction, bridges, tunnels, railway stations, churches, public buildings, colleges, schools, banks, hotel, manufacturing and business buildings, residences, and monumental work. Among the more notable examples of this stone are the present Welland Canal locks; bridge piers on the spans across Niagara River; Brock's Monument at Queenston Heights; power plants of the Niagara Falls Power Co., and the Canadian Niagara Power Co., at Niagara Falls; new Mountain Hospital, Hamilton; new Civic Library, Montreal;St. Henri Church, Montreal; gateway to Rideau Hall, Ottawa; St. Patrick's Church, Toronto; several schools and public buildings throughout Ontario. Also a large quantity of this stone is shipped annually to the United States.

Plug and feather drilling, St. Davids, June 1, 1916.

Additional Information

In a short article which appeared on page 532 of the May 31 issue of The Contract Record, describing the new sub-station of the Mount Royal Tunnel Company, we inadvertently omitted the name of the architect, Mr. C. Gordon Mitchell.

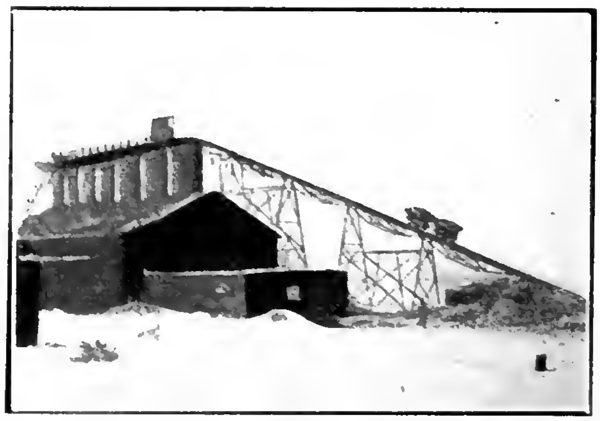
In our article describing the extension of the Montreal Harbour Commissioners' elevator, on page 560 of the June 7 issue of the Contract Record, we stated that the steel was supplied by the Dominion Bridge Company. We have since been advised that the reinforcing steel bars, of which there was a considerable tonnage used in the construction of the elevator, were supplied by the Burlington Steel Company, Limited, of Hamilton, Ont.

The Faultless Hose Reel

The Montgomery Faultless Hose Reel Company, 47 Gore Vale Avenue, Toronto, have made a number of installations this spring of their hose reels in some of the largest public buildings in the country. One of the strong and exclusive features of the Faultless Hose Reel is that it is instantaneously automatic and fool proof. It can either be attached to the wall or built in, in a cabinet form. The reel is so built that the water can be turned on without unwinding the hose as the staves supporting the hose collapse, allowing for the expansion of the hose. This device has been endorsed by the Ontario Government and is being placed in all their principal buildings, including the Toronto Parliament Building. It has also been specified for the million-dollar wing known as the Ross Memorial Wing of the Royal Victoria Hospital at Montreal.

Standard White Lime Hydrating Plant

The hydrating plant of the Standard White Lime Co., Limited, at Guelph, is shown in the accompanying illustration. The same company have works also at Beachville and St. Marys. In these plants are manufactured high calcium, magnesium, and hydrated lime. The Guelph lime runs high in magnesium, which makes it very desirable for strong hydrate. The Beachville and St. Marys plants produce high calcium lime, which is in great demand for chemical preparations and also in steel plants, ammonia and sugar beet factories, tanneries and carbide factories.



"Standard" Hydrating Plant, Guelph, Ont.

At a recent meeting, the reeves of North Essex, Ont., decided to put a good roads system in operation, according to a plan outlined by Mr. George Hogarth, engineer of the Department of Public Works, Toronto.

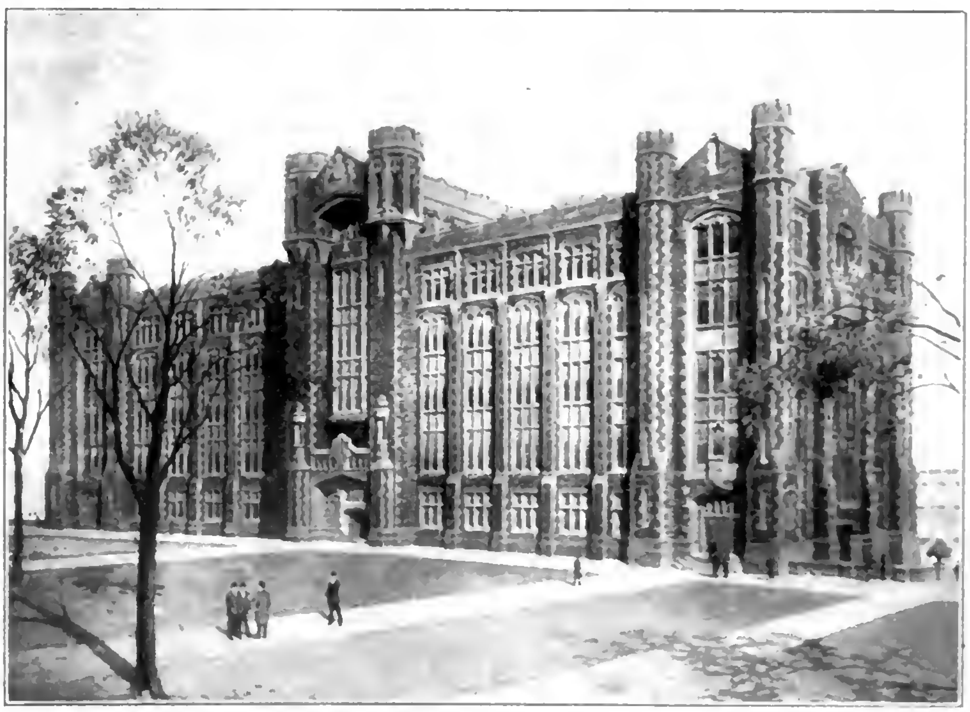
Schaw Quarry Guelph, Ont.

One of the successful limestone crushed stone or rubble stone quarries supplying the city of Toronto and vicinity is that owned and operated by John Maloney. This quarry, known as the Schaw Quarry, is situated west of Schaw, near Guelph, Ont., in the Gore of Puslinch, and about 45 miles from Toronto, on the Canadian Pacific Railway. In this vicinity are wide exposures of rock and many acres of quarry land on which is a very light stripping. The quarry is about 1,000 feet by 300 feet and shows a more regular bedding than is common in the Guelph formation. The upper 14 feet presents stone varying in thickness from two to ten inches. Distinct bedding planes are shown at frequent intervals. Below this level the quarry is opened at a few points to a depth of 11 feet, exposing beds of a rather finer character in layers up to 10 inches thick. An up-to-date equipment at the quarry, including a No. 5 and a No. 3 Gates rotary crusher, gives a capacity of 300 tons per day. Mr. Maloney's head office is at Queen and Dufferin Streets, Toronto. He also maintains a large brick yard at the Humber

D. J. Gordon Granite Company

The D. J. Gordon Granite Co., Gananoque, Ont., have been operating this year, since February 1. Their chief line of business has been manufacturing granite paving blocks, mostly for the city of Toronto. The granite is of two classes—one fine in grain, the other coarse grain. The fine grain is only suitable for paving blocks, curbing, and rough building work. Paving blocks from this stone can be made as clean and trimmed so as to pave as close as artificial brick or wooden block pavement. The coarse grain is red in color, similar to Scotch granite used for monumental purposes. This granite would appear to be strictly adapted for building purposes, this company claim, as there is no granite equal to it now used for such purpose in Canada.

This quarry is the nearest granite quarry to the city of Toronto. They have a large deposit of red granite, more than could be quarried in several generations, and are equipped and make delivery in any form except in crushed form

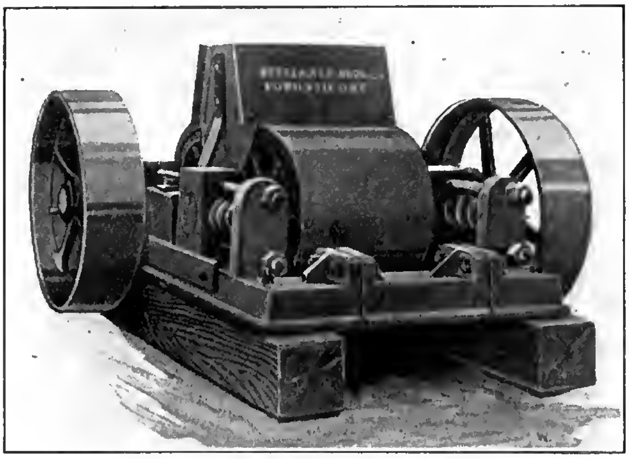


Ottawa Examining Warehouse - Stone supplied by Wallace Sandstone Quarries Company

Improved Crushing Rolls

Messrs. Wettlaufer Bros., 178 Spadina Avenue, Toronto, have placed on the market a line of new and improved crushing or pulverizing rolls, with capacity ranging from 36 to 4,000 tons for ten hours. These rolls are adjustable for crushing rock or stone to any size down to dust, and have shown themselves to be very efficient in stone quarries, especially where increased capacity was necessary, and also where car loads of certain sized rock were wanted for immediate shipment. It often happens that a quarry or stone company has a capacity of certain sized rock per day and are continually in trouble through not being able to supply the sizes called for. With these new rolls you adjust instantly to any size and orders may be executed immediately.

The manufacturers claim that these rolls have re-



Pulverizing Rolls

placed a good many crushers and are giving great satisfaction on account of the wonderful range of their work. They will reduce stone to powder or any fineness desired. Stone dust is now used in many cases instead of sand in making concrete. This is said to improve the quality of the concrete as stone possesses special binding qualities.

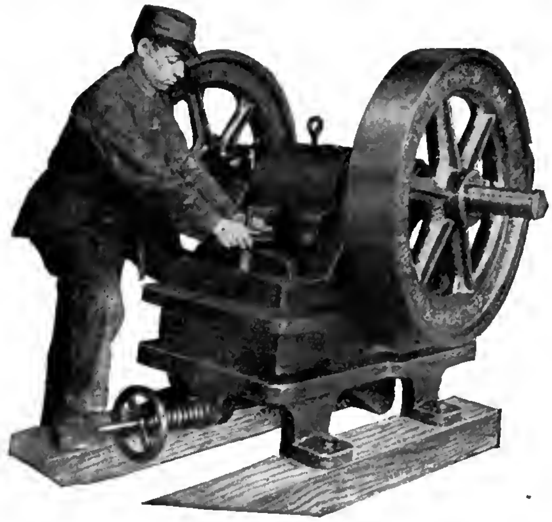
Contractors can use pulverizing rolls for tile, brick and block and it is claimed that at least 30 per cent. is saved in the quantity of cement required.

These rolls are said to be especially effective in gravel plants for crushing boulders and large gravel. In the case of ordinary crushers the gravel will slip through between the jaws without being crushed.

An Efficient Crusher

The illustration shows a No. 3 Wettlaufer improved crusher, manufactured by Messrs. Wettlaufer Bros., 178 Spadina Avenue, Toronto, which has a capacity of 20 to 70 tons in ten hours. The weight is about 6,000 pounds, and the jaw opening 8 in. x 14 in. This crusher is equipped with ring oilers and slip head pitman for wear in the eccentric bearing. All crushers are equipped with bronze babbitt bearing. All plates are made of manganese steel.

Unless otherwise specified the crusher is equipped with corrugated jaw plates. These plates will take hold of larger rock than with the smooth jaws. Smooth plates, however, are recommended where it is necessary to crush rock to a sand fineness. The stationary jaw plate is held in place by key wedges, which form the double purpose of holding in the jaw and also protecting the bed from any possible wear. Where unusually hard material is being crushed the key plates are also made of manganese steel. This crusher has only three bearings, which require less power to operate than the ordinary crusher, with nine and twelve bearings, and the cost of renewing of these bearings in comparison with nine or more bearings is at least 60 per cent. less.



No. 3 Crusher

One of the most valuable features of this crusher is its instant adjustment. The distance between the jaws is regulated by turning a hand-wheel so that a product can be made in any desired size. The single eccentric produces a peculiar crushing and grinding motion in the movable jaw. This is a reciprocating horizontal and vertical motion, which crushes and grinds in the same revolution. It greatly assists in cutting down the amount of power required.

This machine is particularly popular with block and tile manufacturers who require a machine which will crush rock or gravel rejections fine enough for use in their product.

Adam Hill's quarry of Miramichi sandstone, at Cassilis, near Newcastle, N.B., is illustrated elsewhere in this issue. Last summer they had the contract of the new hospital in Newcastle, which took one thousand tons, besides a few hundred tons to other parties. It is a beautiful stone and there seems to be plenty of it. The quarry is on the bank of the Miramichi river—a good water front and a good location.

The Raymond Concrete Pile Co., Limited, of Montreal, have been awarded the contract for the foundations of the St. Maurice Paper Co.'s new plant at Cap de la Madelaine. There will be between 400 and 500 piles. The George A. Fuller Company, Limited, are general contractors.

George W. Tillson, M. Am. Soc. C. E., Henry G. Shirley, M. Am. Sos. C. E., and Arthur H. Blanchard, M. Am. Soc. C. E., a Commission of Engineers, appointed by the Wilmington Chamber of Commerce, have recently submitted a Report on the Administration, Construction and Maintenance of Highways which are under the jurisdiction of the Levy Court of New Castle County, Delaware.

Personal

Major Thos. C. Irving, of the Canadian Engineers, was among those who received King's birthday honors, being decorated with the D.S.O.

Captain G. H. Blackader, reported wounded in the recent fighting, is a member of the firm of Barott, Blackader and Webster, architects, Montreal.

Mr. W. G. Chace, chief engineer of the Greater Winnipeg water district, has been elected chairman of the Winnipeg branch of the Canadian Society of Civil Engineers.

City Engineer Craig, of Calgary, Alta., just recently made a long trip through Eastern Canada and the States and has now returned to Calgary with renewed health and vigor.

Among the birthday honors was the award of the C.M.G. to Lieut.-Col. Ramsay, the C.P.R. engineer, for organizing the railway construction corps, which has done such excellent work in France.

Thos. M. Fyshe, A.M. Can. Soc. C. E., has been appointed Canadian manager for Gunn, Richards & Company, production engineers, Montreal. Mr. Fyshe was a prominent Calgary contractor.

H. Victor Brayley, C.E., has accepted a position as executive assistant to Mortimer B. Davis, a Montreal manufacturer and capitalist. He was formerly manager for Gunn, Richards & Co., Montreal.

Sapper Nathaniel A. Burwash, 6th Brigade, Canadian Engineers, is reported wounded. He is a graduate of the Department of Mining and Engineering in the University of Toronto, and was born at Cobourg, Ont.

Mr. J. C. Johnstone, town engineer, Port Alberni, B.C., now in France with the Canadian Engineering Corps, has won his commission on the field. In the latest report he expected to return to England for a short time on leave.

On the assurance of Mr. P. Mercier, the chief engineer of Montreal, that he could do the asphalt paving work at $2.12 per yard by day labor, against $2.33 by contract, the Board of Control have rescinded a resolution calling for tenders.

Obituary

Mr. Josiah Mason, a well-known Brampton contractor, died recently at his home in that town. Mr. Mason was one of the oldest builders in the neighborhood and many of the fine residences and public buildings in Peel County, Ont., were erected by him.

Mr. John W. Messacar passed away recently at his home in Hamilton, Ont., at the age of 59 years. Mr. Messacar lived the greater part of his life in Millgrove, and for the last ten years had been a resident of Hamilton, where he was engaged in business as a building contractor.

The death is announced of Mr. Edwin Buscombe, of the firm of E. J. Buscombe, at his home in Hamilton, Ont. Mr. Buscombe was in his sixtieth year. He was born in England, but had resided in Hamilton for about 44 years. He had a large circle of friends and took an active interest in many societies, including the Builders' Exchange, of which he was a member.

Mr. C. R. Scholes, of New Carlisle, Que., well known through his connection with various railroad enterprises, died recently at Bermuda, where he had gone on a visit for his health. Amongst the undertakings with which the late Mr. Scholes was connected, were the building of the Caraquet Railway, the Central Railway of New Brunswick, and the Atlantic and Lake Superior Railway. At various periods he was manager of the Salisbury & Harvey Railway, the Atlantic and Lake Superior Railway, the Quebec, Oriental and Atlantic, and the Quebec and Western Railways.

Mainly Constructional

East and West—From Coast to Coast

The Barnes Construction Co., Limited, has been incorporated with a capital of $5,000; head office, Montreal, P.Q.

The Canada Stove & Foundry Co., Limited, has been incorporated with a capital of $1,500,000; head office, Montreal, P. Q.

Wm. Marsh & Sons have established an iron and brass foundry in Port Hope, Ont., and are now open for all kinds of foundry work and general jobbing.

The building permits issued in the city of Toronto for the month of May represent a total value of $988,985. These figures are well over those for any month since 1914

Some of the brick companies in Toronto are appealing against the new assessment. They do not think it justifiable on account of conditions in the brick business at the present time.

The work on the Quebec bridge is proceeding with great vigor. The total amount of steel in the bridge when completed will be about 65,000 tons, and it is probable that the outlay will not fall far short of $20,000,000.

Members of the Ontario Good Roads Association recently took a motor trip over the southern portion of Hastings County and through the County of Prince Edward, to Picton, where they were entertained to a banquet.

The report of the consulting engineers to the Greater Winnipeg Water District, recently submitted, urges the use of concrete pipe instead of steel pipe, as at first proposed, for the portion of the aqueduct between Deacon and the Red river.

Geo. W. Reed & Co., Limited, Montreal, announce that their roofing supply department, carried on for some years, has been extended, covering a full line of supplies for the roofing and allied trades, as well as many lines required by the general contractor.

A new lighthouse is to be erected by the Dominion Government at Triple Island, Brown Passage, on the Pacific Coast. It will be of reinforced concrete construction and will be about 65 feet high. A fog alarm and dwelling house building will also be constructed.

The city of Sault Ste. Marie, Ont., are considering a new water system. Coldwater Creek appears to be favored as the most suitable source for the water supply, but has not been decided upon as yet. A plebiscite is shortly to be submitted to the people on the question.

Work on the Lake St. Francis storage dam in the province of Quebec, an undertaking involving an expenditure of about $100,000, will be completed by October of this year, according to a statement made by Hon. S. N. Parent, chairman of the Provincial Streams Commission.

Building permits were issued at Welland, Ont., during the months of May this year representing a total expenditure of $69,072, as compared with $25,841 in May, 1915. The total amount of the building permits for the first five months of the year is $99,196, an increase over the corresponding period last year of $18,323.

Attention has been drawn in the British House of Commons to a creosote disease of brickmakers. The creosote used in lubricating the brick molds often gets on the hands and arms, and in at least one case the injury has resulted in the loss of a limb. Prompt washing is said to be all that is necessary to avoid harm.

John Quinlan, the Montreal contractor, has lost an action against Westmount City in connection with their by-law prohibiting the use of tractor engines within the city limits. Quinlan had a license from the Provincial authorities to operate such vehicles and was attempting to have the Westmount by-law annulled.

Up to May 31st, 1916, there were 61 permits issued in the city of Galt, Ont., representing a total of $59,351, as compared with 65 permits representing $51,330 for the same period last year. During the month of May this year there were 34 permits issued, total $40,991, while in May, 1915, there were 28 permits issued, total $13,095.

The Federal Government of the Province of Quebec are calling for tenders for the reconstruction of the railway depot at Levis which was destroyed by fire last year. The plans for the new building, which will be one of the most up-to-date depots in the province, have been drawn up by the firm of Ross & McDonald, architects, of Montreal.

At the sample fair in Lyons, France, Canada was represented by a fine number of exhibits illustrating the wide range of our products. The firms showing included the C.P.R., Dominion Bridge Company, Page-Hersey Iron Tube and Lead Company, Toronto; Eastern Car Company, New Glasgow, N.S.; National Steel Car Company, Hamilton; and the Dominion Rubber System, Montreal.

A scheme is under way for the building of a highway from Brandon, Man., to Carberry, through Sewell Camp. Plans and estimates are to be furnished the various municipalities by Highway Commissioner McGillivray, so that each will know its share of the cost. This road, when completed will eventually form part of the main highway from Winnipeg to the western boundary of the province.

Hon. Finlay Macdiarmid, Minister of Public Works, Ontario, has issued instructions that a survey be made of the proposed Ottawa-Prescott highway, to prepare estimates and plans for construction. It is expected that the survey work, which is to be started without delay, will occupy at least two months. If the construction is not commenced this fall, it is thought probable that preparations will be made during the winter for an early start in the spring.

A shipbuilding syndicate, represented by M. P. Cotton, contractor, of Vancouver, is negotiating with the G.T.P. Ry. in regard to the leasing of the G.T.P. plant at Prince Rupert, B.C., for the purpose of building freighters to be operated by the company. It is proposed to build the ships of steel, and application has been made under the Government's legislation to aid shipbuilding, for assistance in the building of four of these ships, which will be of about 5,000 tons each.

The contracting firm of Smith and MacDonald are bringing an action in the Supreme Court against the town of Watrous, Sask., to recover $10,000 damages. The case is based on the allegation that Smith & MacDonald refused to go on with the contract on the ground that they could not finance it themselves and that the town of Watrous would not give them back any money on the hold back of $4,000 which it had been necessary to put up before getting the contract.

Halifax harbor work in the construction of the new Ocean Terminals, is progressing favorably. The railway is almost completed to grade throughout, and the sectional hollow concrete quay blocks have been laid for about 1,300 feet of wall, and the foundations are ready for about 1,000 feet more. The placing of mass concrete foundations at depths from 45 ft. to 60 ft. below low water, is being proceeded with, and about 300 ft. of wall foundations have already been successfully prepared in this way.

Mr. Andrew A. Kinghorn, C.E., Toronto, has been appointed by the Provincial Government to supervise the work of the Toronto-Hamilton Highway Commission. There has been considerable dissatisfaction in some municipalities regarding the increased expenditure on the highway, which was originally estimated at $600,000, but is now to cost $900,000. The matter was taken up by certain members of the Legislature, and the agitation finally led to the appointment of Mr. Kinghorn, in order that the work might be executed in a more efficient and satisfactory manner.

There has recently been installed and put into operation at the Clayburn Brick Company's works, Clayburn, B.C., a smokeless heat generator manufactured by Thomas & Mainwarning, of Nanaimo, B.C. The generator, which is claimed to be a wonderful fuel saver, was installed under the personal supervision of the inventor, Mr. Walter Thomas, and so successful were the first tests of the appliance that he received three repeat orders. Coal is used in the generator, and Mr. Thomas claims that it shows its superiority over oil not only in cost but also in wide range of adaptability.

The Dominion Steel Corporation reports for the year ended March 31 last, the largest profits in its history, net manufacturing earnings rising to $7,004,316, an increase of $3,433,258, or 97 per cent., over the previous year. After providing for depreciation, interest charges, discount on bonds, etc., the balance available for dividends was $3,995,225, as against $855,256 a year ago, an increase of 370 per cent. When the Corporation preference dividend had been deducted and allowance made for the full year's dividend on the preferred stocks of the subsidiaries, the balance remaining as net surplus for the year was $3,015,225.

The Provincial Roads Commission of Quebec recently held their first session, at which they outlined a programme for the reconstruction of the old North Shore Turnpike Trust roads. It was decided that a Government engineer should immediately make a report to the Commission on the condition of the upper and lower roads connecting the city with the Quebec-Montreal highway at St. Augustin, and it is expected that this work will be pushed forward as soon as possible. Reports also on the road to Kent House, Charlesbourg, and through Lorette, will be given, after which tenders will be called, and it is expected that the work will be given out in separate sections in order to finish it if possible this season.

Mr. Alexander Sharpe, mining engineer, recently addressed a representative meeting of the citizens of North Vancouver, held under the auspices of the inter-municipal industries committee, regarding the iron resources of Canada and the apparent lack of interest shown in them. Mr. Sharpe stated that there were almost inexhaustible deposits of iron ore in Canada, and in British Columbia the known deposits had been estimated at 46,000,000,000 tons. He urged that the time was opportune for the establishment of an iron and steel smelter on the coast. The first units of this plant could be put in operation for approximately $1,500,000, and with a little Government encouragement, there was every opportunity for great development along these lines.

Work on the new Levis dry dock in the Province of Quebec is proceeding rapidly. About 300 feet on the river side, together with the entrance, have been completed and the excavation work goes on over the whole site. The power house is nearly finished and concrete is being poured for the foundation of the pump house. A 500 foot tunnel, connecting the inner dock with the pumps, has also been completed; through this tunnel three 42-in. axial flow pumps will be able to empty the whole dock in less than three hours. To keep out the river water, the latest type of rolling caisson will be used. The dock, which will be one of the largest of its kind in the world, will be able to hold any boat up to 1,150 feet long with a 120 ft. beam. To handle smaller boats, a large steel floating caisson is being built, which can be moved into place and then submerged, thus dividing the dock into two parts of any desired length. The total expenditure on the dock will approximate $3,000,000.

The Government is Moving

There is at last some slight evidence that our Dominion Government will interest itself in the most effective method of obtaining that half-million soldiers which it authorized some time ago. Since the date of the original announcement by Premier Borden he has been strangely silent, and the average citizen is entirely mystified as to why the present methods of recruiting have been allowed to remain in operation so long. Presumably there is no hurry for more recruits, but even so, that is no reason why such an economically wasteful plan should be tolerated at a time when it is equally as important to conserve our physical energies as our other resources. We probably have no more inefficient piece of machinery in the whole empire to-day than these exhibitions of recruiting efforts on street corners and in our public meetings. Man after man and officer after officer exhausts himself in vain contortions, resulting in one or two offers, generally inelegibles. At best those men respond who have the keenest sense of duty and honor—all too often the very men who can least be spared at home. We shall be glad to learn that Mr. Borden's government has taken this matter of recruiting in hand. Neither the responsibilities of this war nor its inevitable sorrows are fairly, or justly, distributed.

Entirely Satisfactory?

Mr. J. H. Sherrard, of Montreal, the president of the Canadian Manufacturers' Association, which met in convention in Hamilton during the past week, is reported to have expressed entire satisfaction with the manner in which General Hughes has handled the placing of ammunition orders. His exact words are quoted as follows:—

"Canada's debt to the Minister of Militia in connection with the making of munitions will only be fully known when the history of our part in the war is written, but it is a great satisfaction and relief to Canadians generally, that the unfortunate investigation which has interrupted his very urgent duties has cast no shadow upon his integrity."

With the last part of this remark we hope we can agree, though it is surely somewhat humiliating to feel that our standard of public life has reached that stage where the fact that a man is honest is considered sufficient cause for a public platform demonstration. The other statement in this quotation about our debt to the minister in connection with the supply of munitions it is not so easy to endorse. In view of the facts that have been unearthed during the recent investigation in Ottawa, we should not be surprised to learn that this sentence in Mr. Sherrard's address was not greeted with loud and prolonged applause by the other Canadian manufacturers present.

Water Supply for the Sault

The question of a new water supply for the city of Sault Ste. Marie, Ont., has been carefully considered during the past 18 months. Under the agreement made between the city and the private company which assumed the water and light franchises in October, 1914, the city was given permission to continue operation of the pumping plant in the company's building up to December 31, 1915. Provision has since been made for the electrical sub-station required.

On account of the pollution of the St. Mary's River, resulting chiefly from navigation, the Provincial Board of Health will not approve of the further continuance of the water supply from the present intakes. Several other sources have, therefore, been investigated, and in June, last year, a full report thereon was made for the city by Messrs. Alvord & Burdick, consulting engineers, of Chicago. As there was some doubt expressed in regard to the capacity of one of the schemes that was favorably considered, further records have been taken during the past fall and winter, which have shown it to be satisfactory. At a recent regular meeting of the city council a resolution was passed recommending that this supply be developed and that a plebiscite be submitted to the ratepayers in June, for their approval.

This scheme consists of a supply from a small creek, which is fed by copious springs at its head. The proposed pumping station site would be located at a point on the creek at practically the same elevation as the main portion of the city and distant about 4¾ miles from the centre of the waterworks distribution system. The route of the pipe line would be along a road almost in a direct line to the city. About midway between the proposed pumping site and the city, the line passes over a summit, elevation of which is about 200 feet above the main street of the city, where it is proposed to build a reservoir of about three million gallons capacity. The force main to same from pumping station and gravity line therefrom to the city system will probably be 24-in. cast iron pipe.

Vancouver Branch C.S.C.E.

Elsewhere in this issue we publish in condensed form a paper on "Pneumatic Caisson Developments in America," which was read before Vancouver Branch Canadian Society Civil Engineers at a regular meeting of that body held on the evening of April 13th last by Mr. Ernest George Matheson, Professor of Civil Engineering, University of British Columbia. Mr. Matheson while engaged in the practice of his profession in New York some years ago was chiefly engaged with caisson work in connection with the erection of several large bridges and business blocks, and therefore had to deal with most, if not all, of the problems connected with that difficult branch of engineering science. As a result his paper proved of unusual interest to the large number of C. S. C. E. members and university students who made it a point to be present on the occasion.

The above address brought to a close the program of meetings and papers for the winter of 1915-16. The meetings have invariably been well attended and the speakers well worth hearing. The success of the winter series was due very largely to the zeal displayed by the president of the branch—Mr. R. F. Hayward, general manager of the Western Canada Power Company, Limited, Vancouver, who was indefatigable in his efforts to make each meeting more successful than the last.

Faulty Engineering

Much of the faulty construction and imperfect workmanship occurring in many engineering projects can be traced to the incompetence or inability of the engineer in charge. It is regrettable, to say the least, that in much of the work requiring careful and exact supervision, men of inferior capabilities or uncertain experience are chosen as superintendents. It is essentially of prime importance that those in charge of a piece of work should have such engineering training and skill as will be comparable with the technical requirements of the work and such as will ensure the work being up to the standard laid down in the specifications. Road building serves as a particular example to illustrate a case where incompetence and inability result too often in construction of an entirely unsatisfactory nature, where materials are skimped or workmanship is imperfect and where specifications and plans are not followed. Much blame for such a state of affairs is often, of course, due to lack of proper supervision from working foremen, but with a proper engineer in charge, the conditions causing such imperfections will to a large extent disappear.

The selection of an inexperienced or incapable engineer is often due to the omission of definite details in the specifications regarding his experience and ability. There is a tendency in reports on projects requiring technical skill to leave unstated the exact qualifications of those who are to assume the responsibility of the work or who are to be placed in charge of its construction. Often it is merely mentioned that an "engineer" or a "competent engineer" is to supervise, without so much as specifying the nature of his competency and, as is usually the case, the judgment as to this quality is left in the hands of a non-technical board or commission. The result is, as has often been shown, that a person is chosen who is entirely unfit to superintend the job, due, either to a lack of practical experience in the particular branch of work concerned, or to a lack of the requisite technical skill or training.

This matter might be remedied, at least in part, by the inclusion in the report on the work, of a definition of the requirements needed by the engineer, which would indicate the technical standing he must have obtained and the number of years he must have spent in practical supervision or construction. There is a beginning of reform in this regard, for some of the reports on public or private projects have now inserted in them such a clause as leaves no room for incapable management. The general adoption of this would result in the responsibility being placed in men of proper status and would further tend to ensure that the workmanship and materials are up to a much higher standard.

Classification of Road Materials

The subject of the classification of asphaltic and bituminous materials has for some years been the subject of active discussion in the Society for Testing Materials, the American Society of Civil Engineers and other bodies. A similar discussion has been going on in England. A report on this subject by the Engineering Standards Committee has just been issued. The report divides into three groups the materials now used in binding together the stones and other mineral aggregate used to form road crusts and road surfaces: These are:—

(1) The tars and pitches obtained by the destructive distillation of coal or similar substances.

(2) The bitumens and asphalts which are found in nature, or are obtained artificially from asphaltic oils.

(3) Chemical binders, including the Portland and natural cements which owe their cementing value as road binders to chemical action, and which are not dealt with in the present report.

Hitherto, as the "London Surveyor" points out in commenting upon this report, the term "bituminous material" has been loosely applied to tar products, as well as to bitumens and asphalts, but the committee have from the first considered that it was desirable from the road engineer's point of view, to maintain a sharp line of demarcation between the two groups. The views put forward in correspondence from America and by American engineers of standing and experience have been carefully considered, but the committee still adhere strongly to the view that the description "bituminous" should be applied only to the second group.

In England, the first group of road binders, the coal-tars and pitches, have been in use for many years, and as the Road Board in 1911 issued specifications for the tars, tar oils and pitches which they recommend for road purposes, these materials have already, to some extent, been defined by those specifications. The Road Board, early in 1914, issued a second edition of these specifications. Only two classes of tar and one class of pitch are dealt with, and as these specifications—which form part of the report—are of such recent date, the committee recommend that they be adopted provisionally as the British Standard specifications for tars and pitches used for road work.

The committee find that the choice of names for the second group of road binders is a matter of some difficulty. This difficulty is increased by the fact that, whilst it is desirable to obtain the concurrence of the American engineers to the nomenclature and definitions which the committee now propose, the adoption of the American nomenclature for the various materials composing this group would be liable to lead to confusion and misunderstanding in England.

The committee have been very anxious to secure uniformity with American practice, and have carefully and fully considered the definitions adopted by the American Society for Testing Materials, and by the American corresponding members, but it is felt that the definitions now decided on are preferable from the road engineer's point of view, as they are based on those characteristics of the materials which can be most readily verified when employed for road making. In accordance with this view the committee consider that it is desirable to make a sharp distinction between coal tar and paraffin oil derivatives on the one side and native bituminous substances and asphaltic oil residues on the other, and they are therefore unable to accept the American definition of bitumen—which would include the coal-tars.

The committee's report, the full title of which is "British Standard Nomenclature of Tars, Pitches, Bitumens and Asphalts, when used for Road Purposes, and British Standard Specifications for Tar and Pitch for Road Purposes," is obtainable at the price of 5s. 4d. (post free) either from the offices of the committee, 28 Victoria St. S. W., or from the publishers, Messrs. Crosby, Lockwood & Son, Stationer's Hall-court, E.C.

Activity in Ford City

The town of Ford City has let the contract for the pavement on Belle Island Avenue and for a concrete box drain in the alley west of this avenue, estimated to cost upwards of $6,000. In the very near future the contract for sidewalks, estimated to cost upwards of $3,000, will also be let. Additional construction work during the present season will include a new public school to cost in the neighborhood of $50,000, the plans for which are at present in the hands of the architects. Other building work is quite active, more especially in the way of dwelling houses for working men.

Preliminary arrangements have been about completed for the extension of the concrete pavement, about 15 feet in width, from the 3rd Concession Road, Sandwich East, via Seventh Concession Road, and partly along the side of the Pere Marquette Railway, to Oldcastle, on the Talbot Road, in the Township of Sandwich South, a distance of about 4½ miles; construction work is expected to commence shortly.

Storage of Cement

The one necessary factor in preserving cement is to prevent the access of moisture. It does not require direct contact with water to injure cement, but such is the affinity of the material for water that even atmospheric moisture and wall dampness cause it to become hard and lumpy. The effective preventive of spoiled cement is, therefore, to exclude every trace of moisture. All air circulation around or between the sacks should be prevented so that a damp atmosphere will not come in contact with the cement. A false floor of boards laid on blocks or bricks keeps the material away from the ground. It is necessary also to keep it separated from damp walls. Sacks should be packed as closely together as possible so as to present a minimum outside surface to the air. Other things being equal, paper bags are more efficient in preserving cement than cloth sacks, due to the paper absorbing moisture less easily. When well protected in this way with a waterproof covering fixed tightly, cement may be preserved indefinitely. Sacks should not be turned around or changed from pile to pile. If caked, it is better not to break the cake in order that fresh material may not be exposed to the action of the air.

Asbestos Situation in U. S. A.

The embargo placed on the export of asbestos from Canada to other than British or allied countries is already having its effect on the asbestos situation in the United States. Canada is the world's greatest producer of this mineral, most of which was formerly exported to the United States, free of duty. The order-in-council preventing exportation naturally produced an effect on American manufacturers of asbestos products and, although the embargo was modified to allow them to have crude asbestos under guarantees that neither the crude or manufactured material would be re-exported to countries other than those provided for in the original order, there has been some increase and probably will be a further increase in the exploitation of the available supplies in the United States. Increases in production in Arizona and Georgia with promises of similar activities in other parts, although in many cases of low quality, have to a certain extent relieved the loss due to the Canadian embargo.

Lightning Protection of Water Towers

Water towers, on account of their high and isolated positions, are good targets for lightning. The effective protection of such structures was discussed in a report presented at the meeting of the National Fire Protection Association held last month in Chicago. For wood tanks placed on steel towers, an air terminal should be placed on the point of the roof bonded to the top of the tower by a metal conductor, while a ground wire extending well into the damp earth should be bonded to the bottom of the tower. For steel tanks and towers, the air terminal may be omitted. A metal roof may serve as the air terminal with a conductor connecting it to the tower. High structures require at least two ground rods. The bonding should be made by using a plug soldered to the conductor and screwed into a hole in the steel framework so as to make perfect electrical contact.

Plans and specifications are being prepared for a new office building for the Welland Vale Company (38 x 70 ft.), three storeys high, concrete foundation, brick first and second floors, mill construction, modern plumbing, marble and tile work, hot water heating, electric wiring. Tenders close Monday, June 26th. A. E. Nicholson, St. Catharines, is architect.

Province of Ontario Highways

Interesting Descriptions of the Methods Adopted in Constructing, Maintaining and Financing—The City's Share of the County Roads

DEVELOPMENT work on the highways of the Province of Ontario is very fully described in the annual report of the Department of Highways of the Province, prepared by Mr. W. A. McLean, Deputy Minister, and just issued by the Department. The report states that in the province there are 55,000 miles of roadways, of which approximately 20,000 miles are well graded earth roads, 3,000 miles are surfaced with broken stone, and 19,000 miles are surfaced with gravel. The mileage of surfaced roads is considered encouraging, in that, while many are sometimes in a neglected state and often of inferior construction, these will nevertheless respond more readily and cheaply to the systematic attention which it is the desire and aim of the Highways Department of the Province to encourage. The report notes that the building of important market roads under county systems will be of more extended benefit by reason of even moderate improvement of the local feeders.

The report deals at length with the expenditures made by the various counties of the province during the past year and the methods of obtaining the money for this work. The cost of county roads is also discussed at considerable length, and it is pointed out how much depends on local conditions. For example, in a number of districts where they have no local material for road making, where the subsoil has to be carefully prepared, freight rates paid and so on, the cost may run anywhere from $4,000 to $8,000 per mile. In other districts, however, where there is an abundant supply of stone close at hand, and where the task of the roadmaker is often only that of regrading or laying a new surface over an old stone or macadam road, the expenditure need not exceed $2,500, or at most $3,500 per mile. Where good gravel is easily available, a substantial roadway can be produced for from $1,000 to $2,000 per mile.

A standard form of construction consists of an earth grade, twenty-four feet between shoulders, outside of which are the open drains. In the centre of the grade is placed, for a "single track" road, gravel or stone to a width of ten feet, and a depth varying from six to twelve inches, according to the traffic, subsoil and existing foundation. Good grading and drainage are of first importance. The road should be rolled with a ten-ton steam roller to complete for traffic. If the road is on an important line of through traffic, or adjacent to a city, the earth grade should be twenty-

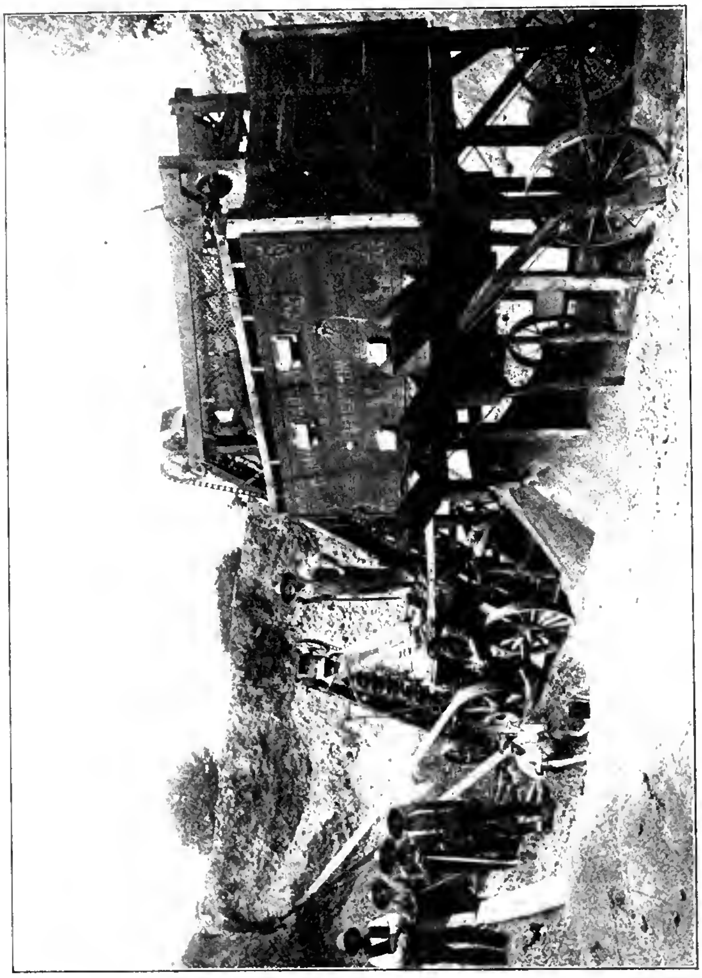
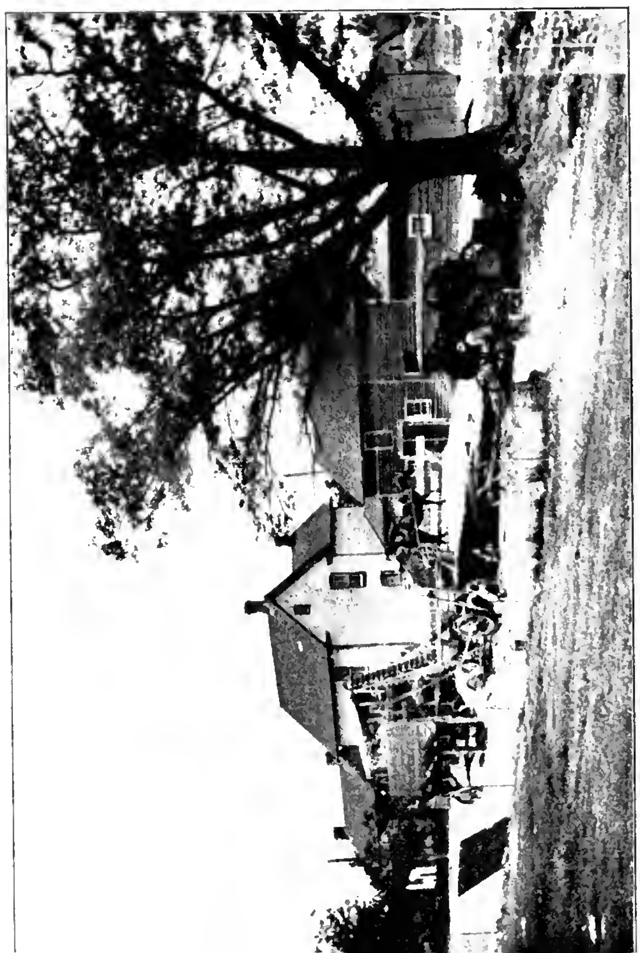
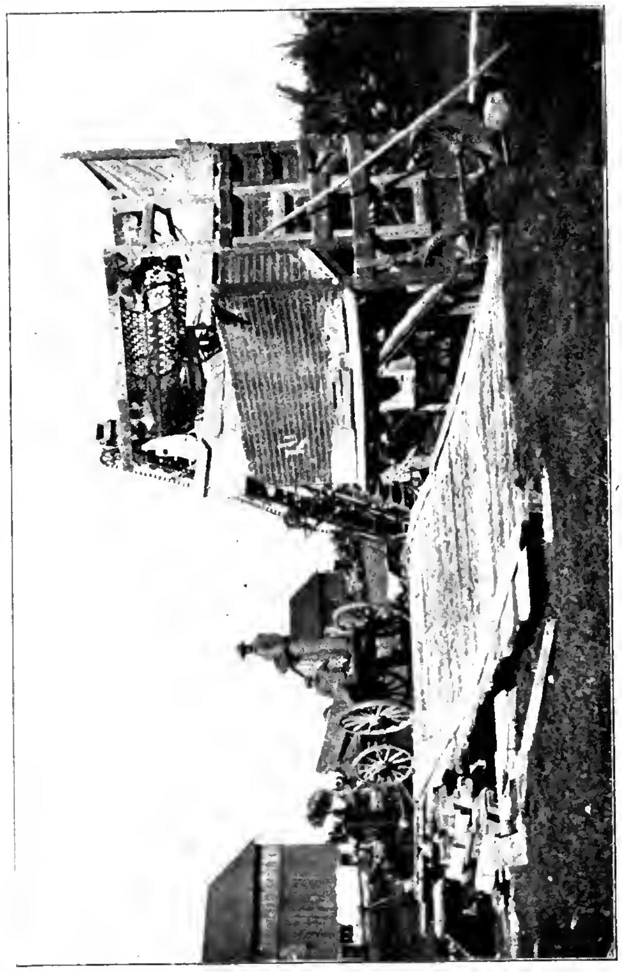
Arrangement of Crushing Equipment—Stone in quarry buckets is raised by a crane to a platform above hopper leading to Crusher.



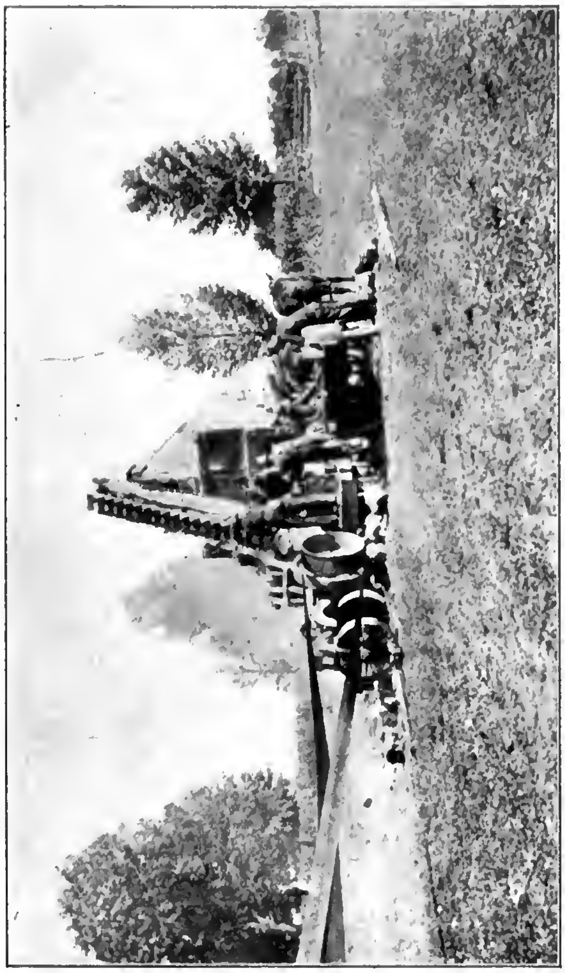
Arrangement of Crushing Equipment. Power from a Traction Engine on top of the bank of gravel; gravel being fed to the Crusher by bucket elevator; material passing through a revolving screen to storage bin.



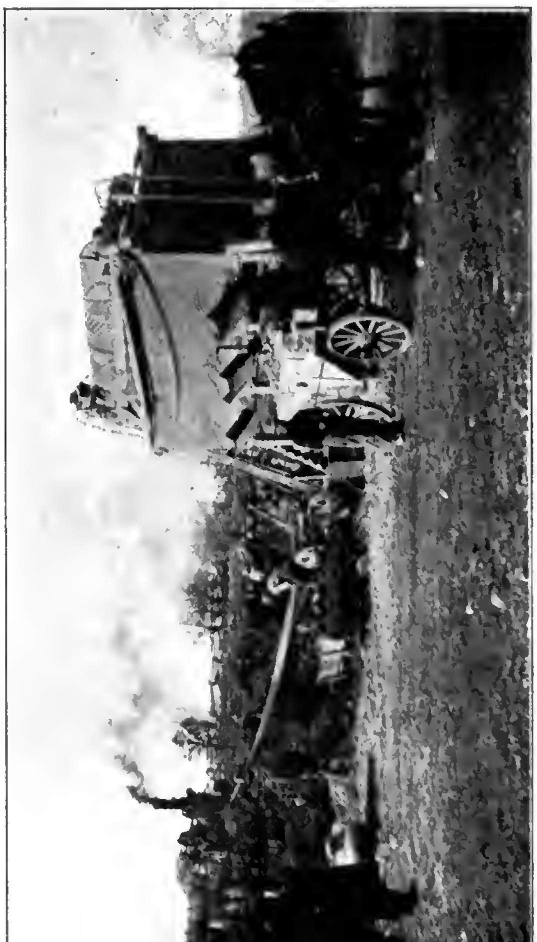
Arrangement of Crushing Equipment—Stone is carried in one-horse carts and is dumped into a hopper from an elevated platform. Three horses and carts are necessary to keep Crusher full.



Arrangement of Crushing Equipment—An elevated platform above Crusher; one team to three wagons; one wagon being emptied; one full; and one being filled.



Arrangement of Crushing Equipment—Inferior method of feeding field stone, being hauled one by one to Crusher, while team is idle.



Arrangement of Crushing Equipment. Stone carried from the quarry face in small cars operated over portable steel tracks.

seven feet wide instead of twenty-four, and provision made for a "double-track" of gravel or stone, eighteen feet wide. This, however, is rarely necessary. A single track of metal nine or ten feet wide may first be laid, and later widened to eighteen feet as traffic increases.

Financing County Road Systems

One of the chief difficulties in the way of better roads throughout the country is the question of financing. The average county council hesitates to add to the tax rate by so many mills on the dollar and often for sentimental reasons they are equally opposed to the issue of debentures for this purpose. On this question of financing county road systems, Mr. McLean's report makes some interesting and valuable suggestions, as follows:—

Alarming but inaccurate statements are met with from time to time as to the cost and debt accruing from county road systems. In financing the work, some counties levy an annual rate on the equalized assessment to meet the yearly expenditure. Others obtain the necessary funds by the issue of debentures. The sentiment of some localities is strongly opposed to the creation of municipal debt; but, by a reasonable compromise, a sound scheme of finance can usually be reached, such as will be practicable, fair, and will not unduly retard progress.

The construction of a system of county roads roads should not be considered solely with regard to the total cost in a term of years, but rather from the standpoint of the annual cost. Road improvement is a process of development which will necessarily extend over a long term of years, and is a perpetual charge rather than a definite capital outlay.

A county rate of 1½ mills on the equalized county assessment should provide a satisfactory annual fund for expenditure on county roads, and should not be beyond the ability or willingness of any county in the province.

For example, to levy a rate of 1½ mills would create an annual expenditure, for each $10,000,000 of assessment, as follows:—

County rate—1½ mills would produce	$15,000
Raised by issue of debentures to meet cost of bridges and permanent construction	6,000
Provincial subsidy, 40 per cent. of total expenditure	14,000
Total for year	$35,000

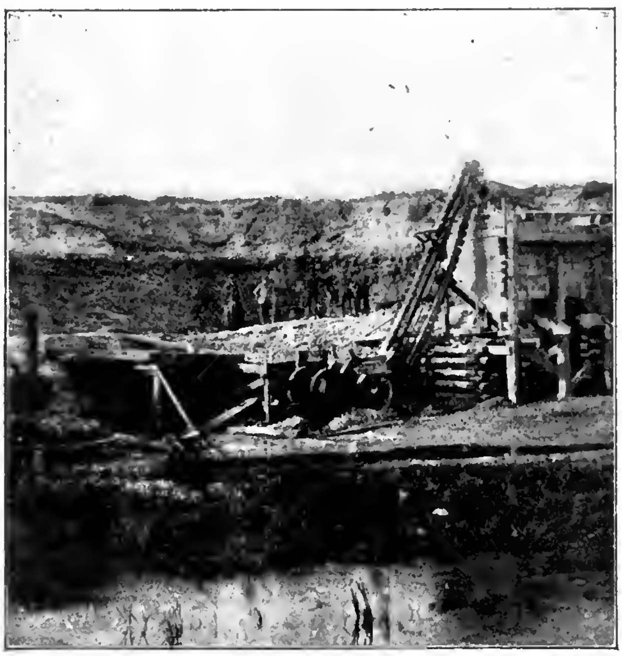
At the end of ten years the net result to the county would be a plan of road improvement representing an asset of $350,000, with a debenture debt of $60,000.

The objection to an annual levy alone is that, without imposing an objectionably heavy tax, insufficient funds are provided; progress is slow, and the gradually increasing demands for maintenance tend to further retard progress of construction. Public dissatisfaction arises from the fact that roads are not being built rapidly enough, maintenance of roads is neglected, and still a substantial tax is being paid. Further, by the annual levy alone, the people of to-day are paying for benefits to which the future should fairly contribute.

The objection to construction solely by the issue of debentures is that property owners of the future may be called upon to pay in part for benefits which they do not receive; while a considerable part is absorbed by interest charges. The sentimental objection to municipal debt is also strong in some localities and must be considered. Further, the immediate improveden of taxation that succeeding councils fear to levy a reasonable annual rate for maintenance. Much depends on the term for which debentures are issued. The Act permits a period of thirty years, but, if confined to ten or twenty years, a sounder basis is attained.

As stated in a previous paragraph, a compromise, a union of the two, an annual levy supplemented by a debenture issue, affords a reasonable and sound method of finance such as will not retard necessary progress, will permit proper maintenance, will not unduly burden the present or future, and will not create an objectionably large municipal debt. By meeting part of the cost of construction by an annual levy, and part by the issue of debentures, the most satisfactory result can be attained. Just what part should be met by the issue of debentures may be estimated from several standpoints, such as: (1) the permanent part of the work; (2) the ultimate cost of maintenance; (3) the ability and willingness of the people of the county to contribute by direct tax.

(1) Certain parts of the work may be considered



Arrangement of Crushing Equipment—Oxford County—Crusher below floor of quarry; limestone fed to hopper over Crusher, and crushed material elevated to revolving screen and storage bin.

permanent, such as concrete bridges, grading, hill-cutting and drainage. The cost of such permanent construction may be estimated, and raised by the issue of debentures; while a further amount to construct, maintain and meet the annual payments on the debentures may be met by annual levy.

(2) The probable cost of maintenance for the completed system may be estimated, and, together with the annual payment on debentures, this sum may be raised as soon as the county system is assumed. The cost of maintenance for the first few years is small, and the difference can conveniently be put into construction, to be supplemented as needed by funds raised by the issue of debentures. As maintenance costs increase, a larger amount will be needed from the debenture fund—but the total debt need be comparatively small.

(3) In case the ability and willingness of the people permit, a still larger sum than is ultimately needed for maintenance may be raised when the system is first assumed, thereby still further reducing the necessary debenture debt.

Broadly, when a county adopts the policy of raising a substantial sum annually (to be supplemented, as required, from debenture issues), the difficulty of financing the work is by no means burdensome, and the method is financially sound above all criticism.

The report futher deals with the highway legislation enacted by the Ontario Legislature at their last session, which has already been dealt with in the Contract Record. In defense of the principle contained in the Ontario Highways Act, that cities should contribute to the construction and maintenance of main roads and leading market roads adjacent to the city, conditions in a number of U. S. states are quoted, as for example, New York, where 85 per cent. of the cost of the state roads is paid by the city of New York; the city of Detroit is paying 85 per cent. of the cost of the concrete roads of Wayne County; the city of Cleveland is paying annually $800,000 for roads outside the city; and the city of Boston is paying 65 per cent. of the expenditure on the state roads of Massachusetts.

An appendix deals fairly completely with the four topics, county road inspection, tests of materials, non-asphaltic road oils, and traffic census statistics. In connection with the report on county road inspection, submitted by assistant engineer W. Huber, a number of very interesting photographs, representing the arrangement of crushing equipment in various counties are shown. Through the kindness of the Highways Department, these photographs, as well as a number of others dealing with roadways' matters, are reproduced in our present issue.

Monastery in Quebec

A contract for the construction of a monastery at the corner of Ste. Foye Road and Bell Avenue, Quebec, has been let to Mr. L. G. Fauteux, St. Benoit, P.Q., the plans having been drawn up by Mr. C. Bernier, Montreal. The building, of five storeys, is on a site 125 x 52 feet, and will be connected by a corridor with a temporary church now existing. The monastery is for the Peres du Tres St. Sacrament, and will cost $82,000. The exterior is of plastic brick, supplied by the Citadel Brick Company, with Deschambault stone trimming; and similar stone will be employed for the exterior up to the first floor. Interior finish and partitions will be of plaster, while the floors are to be hardwood, which will also be used for all other woodwork. The heating will be hot water on the Briset system. On the ground floor will be located the kitchen, dining room, parlor, and reception room; on the other floors provision is made for recreation rooms, library, toilets, chapel and infirmary, the balance of the space being for a large number of bedrooms. A garden roof is also provided.

Milton Pressed Brick Co., Ltd.

A large brick amalgamation has just been completed by which the Milton Pressed Brick Company, Limited, of Milton, takes over the Toronto Pressed Brick Company, of Milton, and the Medina Shale Brick Company, of Streetsville. The new company will be known as the Milton Pressed Brick Company, Limited; capitalized stock $1,500,000. J. S. McCannell is president and managing director of the new company.

This is the Age of Rapid Construction

A Number of Specific Instances Where Modern Methods Aided Speedy Building Operations—A Big Chemical Plant for Quebec

Scattered over a U-shaped area a mile long, covering 460 acres, a great powder plant, costing upward of $1,500,000, was recently completed in five months at Drummondville, Que., by an American firm of engineers and constructors. Two acid-making plants added to the original contract have since been built at an additional cost of $500,000. No unit of the plant was difficult of construction, but the work as a whole required extensive clearing and grading, the construction of seventy-five concrete, brick and timber buildings and a railroad yard, the installation of heavy machinery and the fitting of an extraordinary quantity of pipe.

The plant will be operated by the Aetna Chemical Company of Canada for the manufacture of guncotton and smokeless powder. It is located near the French-Canadian village of Drummondville, Que., which has a population of only 3,000, and which could neither furnish nor house the 2,000 workmen required to push the plant to rapid completion. The powder works will draw water from its own filter plant on the St. Francis River. It is located near a branch of the Canadian Pacific Railway, from which a permanent siding and yard had to be built for the plant.

Plans Made Quickly

The site was selected at the time of the signing of the contract. A preliminary survey was at once made and a general layout established so that construction was actually started within two weeks. The general layout of the plant, which is U-shaped, places the sulphuric-acid plant, nitric-acid plant, cotton stores and cotton dry house in the order named from south to north along the east side. The remainder of the guncotton plant and the press houses of the smokeless powder plant are located on the main east-and-west axis, and the balance of the smokeless plant on the west side.

All the buildings except the pump house, power house and magazines were constructed of timber. The power house is combination brick and timber. The magazines were built with tile walls and reinforced-concrete roofs. All important foundation work is of concrete. The steam, air and alcohol piping has been carried above ground, the high pressure hydraulic lines at the surface in boxes and the water piping in trenches at least 6 feet deep to provide against frost.

Materials Assembled Rapidly

The first task of the constructors on being ordered, July 20, 1915, to proceed with the work, was to assemble at the site the plant and the large quantities of material needed. The plant was loaded immediately at Montreal and reached the site in two days. Having kept in the closest touch with the market, the firm was in a position to place the main orders for material to good advantage at short notice. The capacity of a good-sized lumber mill at Drummondville was investigated, and its entire output was at once contracted for in small-dimension sizes. The large timber was bought at once from Montreal dealers. The entire output of a brick kiln at Mitchell Station, near the work, was bought up. Arrangements were made at Drummondville for the exclusive use of its rock-crushing plant, which, when pushed to capacity, could just supply the job with aggregate, and contracts were made with the local farmers for delivering boulders to be crushed. Good sand in large quantities was found at the site.

Key Structures Attacked First

The detailed design of the plant and the supervision of the construction were carried out by the constructors under the guidance of the Aetna Company's engineers, with the result that the work was harmoniously planned and executed. There was little waiting by the construction forces for plans to be delivered, and all details were worked out in time to have the necessary material at the site when it was needed. Two main features were at once recognized as the keys to the rapid completion of the plant. The first was the railroad yard, which the constructors needed to get in materials and plant, and the second was the power house—a heavy piece of construction which was started at once and finished within 104 days. The grading required was in sand and was not heavy. It and the clearing had to be done immediately, and both were started July 20 with local labor, teams and scrapers. This work was practically completed by September 1. As rapidly as possible a large, well built camp was constructed on the site to care for 2,000 men sent up from Montreal. This was made a permanent camp for the use of the operating forces by the addition of a club house and separate cottages. Meanwhile the railroad yard was partly graded, and the entire three miles of trackage was laid and in use by August 15. Two weeks later the yard had been completely graded and the tracks put in permanent shape.

Difficulties with Water

As soon as possible the foundation work was started. The site was elevated, and it was not expected that water would be found in the excavation for the foundations and the numerous pipe trenches. However, water was encountered in all of this work about two feet below the surface. Pumps were at once secured, and the difficulty was met with hardly the expense of a day's delay. Following the excavating crews were five gangs with portable mixers, supplied by teams, putting in concrete foundations. After them came the crews erecting the timber frames. A very limited use was made of steel in the construction. The future contents of the buildings made fireproofing somewhat superfluous, and the lighter, cheaper construction adopted is considered more economical in the long run. The buildings are spaced widely, and under these conditions are amply protected from fire.

All the buildings are linked by an industrial railway along which the materials are transported in the course of manufacture from the acid plants at one end to the finished smokeless powder at the other. A locomotive crane spotted the cars carrying the equipment of presses, tanks and other heavy apparatus and unloaded them on runways on which the machinery was moved into various buildings before the completion of the outside walls. Wagons were used for transporting all other materials on the job. Only one motor truck was employed, because road conditions were poor. This truck hauled small plant and rush supplies from the Intercolonial Railway, over which a fast express service from Montreal was available.

Mixers, pumps, hoisting equipment, etc., were independent steam units. About 100 horsepower in electric current—all the local company could supply—was used for lighting, and for temporary operation of the permanent pumping station.

Strong Overhead Organization

To secure efficiency from a maximum of 2,300 men drawing wages of $45,000 weekly, a strong organization was necessary. At its head the engineer in charge was responsible, with the help of the main office, for having all designs ready, all materials on hand, all work laid out and orders issued in accordance with the construction schedule. Under him the general superintendent had entire charge of the actual work of creating the plant. His force comprised not less than ten general foremen under whom in turn were foremen in charge of each of a large number of scattered crews. The classes of labor requiring general foremen were the excavating and concrete forces, with two general men; the timber-framing and erection crews, the brick layers, the men engaged in installing the machinery and the pipe fitters. In addition the construction of the yard, power plant, acid plants, and filtration plant were each treated as separate units and put in charge of a general foreman with a complete organization. This system worked well, as the units which were important time factors were in charge from start to finish of one man who was responsible for their completion to schedule, while the main force for the large number of smaller units was kept mobile so that it could be thrown where needed for the greatest economy and speed.

Acid Plants Delay Completion

During the construction it became evident from the growing scarcity of nitric and sulphuric acid that the Aetna Company would have to build its own acid plants. But for this the guncotton end of the plant could have been put in operation November 15, sixteen weeks after the contract was signed, and smokeless powder could have been manufactured by December 15, a month later. The nitric-acid plant, first decided on, was completed early this year, and the sulphuric-acid plant is now being built. The total outlay for the completed plant represents $2,500,000, of which cost the construction work comprised four-fifths. The work was carried out under the direction of the engineering and construction forces of the Aetna Explosives Company by Westinghouse, Church, Kerr & Company, whose representatives were J. H. O'Brien, managing engineer, F. E. Caldwell, engineer in charge, and John Lydon, construction superintendent.

Simpson Mail Order Building

The accompanying illustrations show the progress that has been made on the new mail order building of the Robert Simpson Company on Mutual Street. A general description of the structure appeared in the Contract Record of April 26th. The cuts show the comparative conditions on April 1 and June 1, and demonstrate the rapidity with which Wells Brothers, the general contractors, are advancing the work.

Fig. 1 shows the preparation for excavating the foundations. Owing to the soil being unsuited for a spread foundation for a building of this type, concrete caissons were used, seventy-eight in all, varying in diameter from four to six and one-half feet, and extending 43 to 46 feet to bedrock. An interesting method of reducing the labor in their construction was used, by which it was possible to excavate for thirty-eight caissons at one time. An endless chain was run from the engine shown in the illustration, Fig. 1, up and down through three rows of tripods, back to the engine. This chain was continually moving. As the buckets in each hole were filled by the excavators, they were attached by their rope to the moving chain over the niggerheads which can be seen on the tripods. The buckets were thus pulled up, dumped and then lowered to be again filled. The endless chain covered thirty-eight holes altogether, so that any or all of them could be excavated at one time. Thus by only two settings of the equipment all the caissons were dug, which expeditious method contributed materially to the rapidity with which the work has been carried out. On account of the large amount of water in the sub-soil continuous night and day labor was required until the pouring of the concrete was com-

Fig. 1—Simpson Building, April 1.

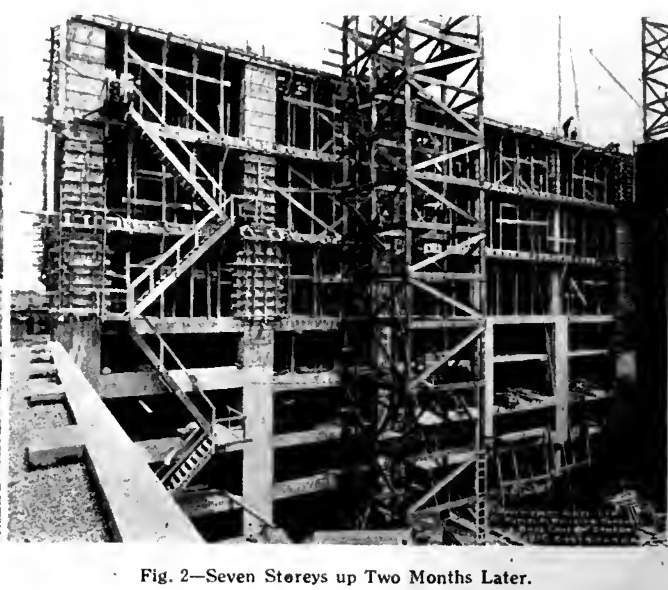


Fig. 2—Seven Storeys up Two Months Later.

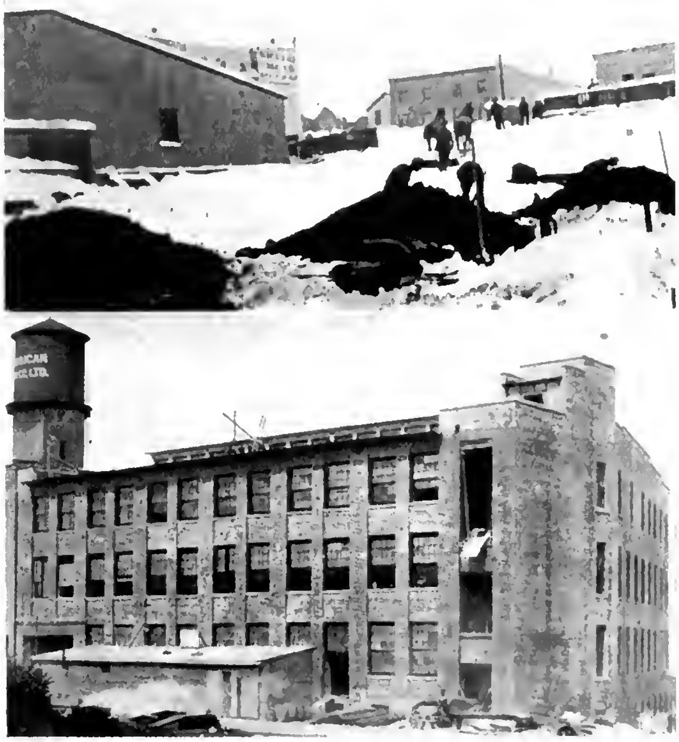
pleted. This prevented any undue accumulation of moisture.

Fig. 2 shows the conditions on June 1 with five floors up. The framework carrying the derrick is shown. This is continually being extended upward as the construction continues, and it serves also as a guide for a hoist.

The building, although as yet far from complete, will, it is expected, be finished this fall. As evidence of the rapidity of the work, the first slab was poured on the 19th of April, and the construction is now at the seventh floor.

Record in Vancouver Building

When the American Can Company, Limited, built their large factory on Railway Street, Vancouver, three years ago, it was with the thought that they would have ample accommodation for a number of years. Such, however, has been the very rapid progress of their business that early this year they found it necessary to arrange for a big extension. On February 3, the contract was let for a three storey and basement addition, consisting of 129 feet frontage by



Upper, Starting Excavation, Jan. 8. Lower, Building Complete March 8.

a depth of 125 feet. The new building will give a floor area of 60,000 feet, and a considerable quantity of this space is immediately required for storage purposes.

The Dominion Construction Company, Limited, Vancouver, made good time on this work. When they started excavating on February 8, the ground was covered with snow, and during a good part of the interval they have been deluged by rain. The carpenters are now busy laying the maple flooring, the concrete basement is under way, and the building will be ready for occupation in a very few days. The floors are of 3-in. fir, covered with factory maple.

New Machine Shop and Power House, St. John

Grant & Horne, engineers and contractors, St. John, N. B., have just been awarded the contract for the erection of a new machine shop and power house for T. McAvity & Sons, St. John. The machine shop will be eighty-one feet wide and 401 feet long. At the front, fronting on Marsh Road, there will be four doors and at the rear two reinforced concrete loading platforms, ten feet wide and forty-seven feet, ten inches long; one will be devoted to receiving raw material and the other to shipping the finished product. Along the rear will run the I. C. R. spur track for handling freight and also delivering coal to the power house. The construction of this building will be of reinforced concrete with hard pine framing inside. Two rows of supporting posts, spaced twenty feet apart longitudinally, will divide the floor space into three bays. The building will be one storey in height with a clear space of sixteen feet to the lower roof beams. The floor will be of reinforced concrete throughout and the structure will be well lighted by steel sash windows on the sides and a saw-tooth skylight in the roof.

The power-house will be built of brick with steel trussed roof, and will be seventy-seven feet, eight inches long and thirty feet wide. It will contain the boiler and engine rooms and will be twenty feet clear height in the engine room and twenty-five feet in the boiler room. The floors will be of concrete and brick. In both buildings the roofs will be of mill construction and a sprinkler fire-protection system will be installed throughout. The foundations will be of concrete and piling, 200 piles being used, and of these seventy will be required to support the chimney stack. The stack will be 150 feet in height, diameter six feet at top, and is to be built of radial brick by Kellogg & Company, of Montreal. The plant used by the Grant & Horne Company for this work, which is now under way, consists of three concrete mixers, each of a capacity of seventy-five yards a day; an engine for hoisting timbers; derrick; two elevator towers; piling engine and pile driver with 2,800 pound hammer. Work is to be completed by August 1.

The same company have just completed a concrete floor on Brown's Mill-dam Bridge at Bathurst, N. B., a raw sugar shed extension for the Atlantic Sugar Refinery at St. John, and have contracts in hand for a concrete floor on the Covered Bridge at Covered Bridge Station, near Fredericton, N. B.

Belt Dressing

There are many dope dressings on the market that should never be used except to ruin a belt. A few dollars more each year for a good dressing will soon save itself in the increased life of the belt. Some substitutes, such as linseed oil, soap, resin, grease, or any old kind of oil have been recommended for the cure of temporary belt slip. It stands to reason that a hard smooth surface will cause the belt to slip. Neats-foot oil and castor oil are often recommended, but they should be discarded in favor of some of the valuable belt dressings on the market. The principle to follow is to keep the belt pliable

The introduction of dust removers in granite sheds has been developed to such a stage of perfection that the fatal dust menace of the workers seems to be in a fair way of being eliminated.

Park Avenue Grade Separation in Montreal

In order to give better facilities in the north end of Montreal, the city has opened the Park Avenue subway, under the C. P. R. tracks between Van Horne Avenue and Lannes Street. Prior to the construction of the subway, pedestrians had to cross a level crossing, and vehicles had to make a considerable detour in order to get to the other side of the tracks. The subway was designed, on instructions from the city, by Mr. J. Emile Vanier, engineer, Montreal, and the contract let in November, 1914, to Laurin, Leitch and Company, Montreal.

The length of Park Avenue is 800 feet, running south and north, and 330 feet on Van Horne Avenue, running east and west. The bridge, 80 feet wide and 17 ft. 5 in. from the ground, carrying the C. P. R. tracks, is a heavy steel structure, with sidewalks on either side and reinforced concrete panels, pilasters, etc., hiding the steel work and at the same time carrying the architectural lines from the retaining walls and along the bridge. The retaining walls, with panels and pilasters, are crowned with an ornamental balustrade, the whole being in concrete. The distance between the retaining walls is 66 feet, while the roadway is 50 feet wide; there are double lines of street railway tracks, and steel trolley poles between these on the roadway. The paving is of scoria blocks. It was found necessary to divert the sewer and water pipes from the centre of Park Avenue; these are now situated on a side street to the west of that thoroughfare, the city having expropriated land for this purpose. The surface water running down the subway is collected by means of a system of gullies and a collecting wall, from which it is pumped by an automatic electric pump into the new sewers.

On the southwest corner stone steps lead from the roadway to the sidewalk, the ground there being on a higher level. These steps give access to some shops at this corner.

The lighting of the subway is from 14 ornamental lamp posts surmounting the concrete balustrades the entire length of subway and 18 high power lamps placed under the bridge above the roadway and the high level sidewalks.

The excavations in the subway totalled 25,000 cubic yards of earth and 12,000 cubic yards of rock. The concrete work amounted to 4,000 cubic yards, while there are 8,000 square yards of scoria block paving.

The machinery used was chiefly driven by electric power and gasoline, only the steam shovels being run by steam. The contract was executed within the specified time, 16 months, and the work was done without a cent extra on the contract price of $176,176, and without any alteration of the original plans.

It was a condition of the contract that there should be no interruption of C. P. R. traffic. It was therefore necessary to build the subway and bridge in two sections; first the south half of the excavation was done, the retaining walls constructed, and the steel put up, thus enabling the C. P. R. to use during the work three lines of track. When this was completed, the railway company laid their rails on it, and the work on the north part of the contract was commenced. The top of the bridge is covered with waterproofing material and broken stone ballast. On account of surrounding property, special precautions had to be taken to prevent damage by blasting the rock, which was Montreal gray limestone. When the rock had been blasted, it was removed by steam shovels. The C. P. R. have now laid seven lines of track on the bridge, in place of six. The steel in the bridge work was supplied by the Dominion Bridge Company.

Will Use Wood Blocks

The committee on streets of the Seattle Municipal League, after five months of investigation of the merits of various forms of pavements now in common use and the manner in which these pavements have stood up under actual wear, has recommended that creosoted wood blocks be used for the improvement of the East Marginal Way, a big street improvement project which is being worked out for the future development of the city.

Motor Trucks for Deliveries

Dealers who use auto trucks extensively for deliveries are noticeably those who have the reputation of being good business men. The auto truck materially widens the circle of economical service from any given yard and in this way is a business builder.

Fulford Home for Aged Women, Brockville—Hugh G. Jones Architect.

Fulford Home, Brockville

We reproduce herewith an illustration of the Fulford Home for Aged Women, now under construction at Brockville, Ontario, from designs prepared by Mr. Hugh G. Jones, architect, of Montreal.

The cost of this work, amounting to about $80,000, is being provided out of a bequest to the Brockville General Hospital by the late Senator Fulford. The extreme dimensions of the building are two hundred feet frontage on King Street and one hundred feet on First Avenue. The general design of the building is along the lines of the early Tudor Farm or Manor houses. The building contains 42 bedrooms, dining room with seating capacity of 50, library, two storey living room, diet kitchen, hospital, matron's and nurses' rooms, kitchen, staff dining room and laundry, two enclosed porches and one sun room. Provision is also made for future extension.

The exterior is being constructed of McArthur brick laid with wide joints, slate roof and stone trimmings. The floors, stairways, and all principal partitions, are hollow tile and concrete fireproof construction—exterior walls terra cotta blocks brick-faced. Floors generally are of concrete; battleship linoleum is to be laid directly on the concrete in bedrooms, dining, and living rooms. The trim is in fumed oak, except in the bedrooms and toilets, where it is pine, white enamelled. The toilets have ceramic mosaic floors and cove, and Keene's cement enamelled walls, including bath and toilet partitions.

The contract for carpentry and masonry has been let to Mr. A. Cameron, of Alexandria, Ont.; roofing and sheet metal to McFarlane Douglas, Montreal; plastering to McNulty Bros., Montreal; tile and mosaic work to the Robert Mitchell Co., Ltd., Montreal; electrical work to A. G. Dobbie, of Brockville; heating and plumbing to Geo. Ross & Co., of Brockville. Linoleum floors are to be supplied by Murray-Kay, Limited, Toronto.

Sudbury Business Block

Work on the Stafford business block, corner of Durham and Larch streets, Sudbury, is making good progress. The block will be three storeys and basement high, of steel construction with pressed brick facing. The brick of the building will be finished with a raked joint, the first building in Sudbury to employ such a joint. The block will be used for stores and offices, the ground floor and the basement as a store and the upper two floors for offices. The store will have a metal front of plate glass show windows. Heating and ventilation will be by Spencer boiler and Kriebel Baker vacuum system. The block is being built for F. M. Stafford by the Le Barge Lumber Company at a cost of $50,000. Ellis & Ellis, Toronto, are the architects.

The Stafford Business Block, Sudbury—Ellis & Ellis, Architects.

The History of Pneumatic Caissons

A Story of the Development and Description of the Methods Adopted at Various Points on this Continent

By E. G. Matheson*

IN 1852 Dr. Potts' Vacuum Method was tried to sink a six-foot cylinder through 25 feet of sand in North Carolina, at the Pedee River. Then they tried the Plenum Pneumatic Method by pumping in air—the introduction of this method in America.

The second application of the latter method in America was at the Third Avenue bridge over Harlem River, New York, about 1860, followed by the St. Louis Eads bridge and the Omaha bridge by Sooysmith about the same time (1868); then the Brooklyn bridge in 1870.

The largest undivided working chamber was the Hartford stone arch bridge, 131 x 46 feet. It was a timber caisson with a deck four feet thick.

The first building to be erected on a pneumatic caisson was the Manhattan Life building, 66 Broadway, New York, in 1893.

Foundations—History of Development

The Pneumatic Caisson Method for the construction of foundations is used to overcome the influence of hydrostatic head on an unstable or quick soil, or where an abundance of water cannot be combatted in any more economical manner. The method has its limitations. It is seldom employed for depths under 30 feet, owing to its high cost, but for this depth and even less conditions are sometimes met which make it a necessity. On the other hand, when the hydrostatic head to be overcome requires an air pressure of over 50 lbs., its employment involves too much risk to the lives of the laborers to justify its use. Also, the cost of the work, at this depth, is very great, as two shifts of about forty-five minutes each constitute a day's work. Between these depths, however, (30 to 115 feet), the method is perhaps the most satisfactory now in use, affording, as it does, a careful inspection of the foundation beds; and in consequence the area of pier may be so reduced, if conditions warrant it, as to materially lessen the cost, or the area may be enlarged if nature of underlying material so demands. Like most branches of engineering, caisson work has been a growth. The originators of many ideas now accepted as best practice are entirely unknown, while again, other ideas of much less value have been granted patents the infringements of which have been and will be the cause of much litigation.

The power of air, or other gas, to exclude water from an inverted vessel was early known. During the first decade of the 16th century two Greeks at Toledo, for the amusement of Charles V., entered an inverted chaldron with a light, were submerged, and when brought to the surface the light was still burning and their garments still dry, to the astonishment of all beholders. Early in the 18th century Dr. Halley, of the Royal Society, described the use of the diving bell, and under his direction air (Pabulum Vitae) was first delivered to those within to sustain them for long intervals. The possibility of doing work under water was suggested by Halley. It was not, however, until 1778, while Smeaton was repairing the shoeing of a bridge at Hexham, that the bell was actually used on construction work. In this case the top of the bell was above the surface. Subsequently to this, at Ramsgate, Smeaton forced air through a hose to the diving bell, which was used to remove stones in clearing the site of a pier foundation.

The next advance was made by Sir John Rennie in 1813, while engineer for Ramsgate Harbor. This was a cast iron chamber, with glass bullseyes, or windows, in the top. Chains were attached to the underside of the top in order to carry heavy weights, and seats for the workmen were provided. The whole machine was raised or lowered in the correct position by tackle suitably located. The bell was moved by those at the surface on certain signals from those below, given by strokes of a hammer on the bell.

In 1830 Thomas Cochrane took out a patent for a compressed air shaft, but the first application of the air shaft, or caisson, was made about 1839, by M. Triger, on the River Seine at Loire. About this time he also employed it in a coal mine near Chalons. Since that time the development of this method has been some modification of the air shaft idea, retaining the working chamber at the bottom more or less air-tight, with its cutting edge walls and its deck, through which pass the pipes for transmitting light, signals and air, and sometimes for discharging the materials excavated, and also one or more shafts for the passage of men, earth and tools. Above the deck the caisson shaft (or pier), was continued by a cofferdam, which may or may not be filled with masonry, or only partly filled. This masonry may be so firm by the time of sinking the cofferdam that forms from the deck upward may have been removed to be used elsewhere. This is to-day the usual practice. Each of these several parts should be discussed separately and in order.

The Cutting Edge

First, the Cutting Edge—This at one time was supposed to do what its name implies, and was made occasionally of cast iron, but usually of a more or less elaborate combination of steel shapes, as plates, angles and channels running as high as 200 per lineal foot. This method has been largely discarded as a useless expense. Of course, conditions have justified, and will continue to justify (in particular cases) such cutting edges, as when a caisson of considerable weight must be located or set on a river bottom in deep water. It may happen that some irregularity of the bottom may set up very great stresses in caisson. In such cases too much attention cannot be given to preventing any distortion or rupture of the parts of the working chamber. Where, however, it is possible to keep the cutting edge under the direct attention of the "sand hogs" or workmen, no elaborate cutting edge is necessary.

The writer has in mind one case where a long and well supported cutting edge was a decided advantage. Six caissons, each about 18 feet long and 5 feet wide, were sunk through buried crib work. There was only

* Professor Civil Engineering, University B. C., Vancouver.

enough black mud to render the water non-transparent. The remainder of the material consisted of rock and round timber, which was always under water. The rock had to be removed by the use of bars, and the timber had to be cut by means of wood chisels and hammers, in such a way that the caisson could pass freely between timber left on either side. The long V-shaped cutting edge was here an almost indispensible requisite. Ordinarily, however, an angle on the outer bottom edge of the timber side wall of the working chamber, or a channel on the bottom, is all that is required. In fact, if the caisson should continue to slide gently down, as it usually does at first, no special protection is needed, but, as the depth increases the motion of the caisson usually consists of short, sudden drops, which is quite likely to deform a cutting edge of wood only, particularly on the outer edge, which will soon cause the bottom of the sides to move inward and the caisson to assume the form of a blunt wedge, making sinking very difficult. If the side walls are of wood perhaps the best protection would be a channel with the flanges upward and bolted to the timbers. If the working chamber is of concrete entirely, an angle with bolts concreted in and the walls reinforced is very satisfactory.

Side Walls

The Side Walls.—These have been made of steel, wood and reinforced concrete. The condition existing at the site, or the purpose of the work, may dictate the material to be used. Where the outer form constitutes the lining of a large shaft, requiring much clearance, steel plate with internal strengthening angles makes a very desirable form of structure, although wood and concrete may serve fairly well. Perhaps wood is the most serviceable where cheapness and speed, as well as adaptability (an important point) are desirable. These walls should be of a strength—whatever the material used—sufficient to withstand the earth pressure, together with the necessary stresses developed by the methods adopted in sinking. There are those who urge that if the outside faces of the walls are battered the frictional resistance to sinking will be greatly reduced. This is not always so, as stones and gravel loosen, roll against the walls, and exercise a binding or gripping effect which often offers more resistance than the ordinary friction, and by concentrating pressure may rupture the side walls, which (when of wood) have a cross section of from 6 x 6 in. to 12 x 12 in. It is also a fact that a caisson with battered side walls is most difficult to keep plumb, or what is the same thing, to keep in the same position.

There is another effect which makes such a caisson more objectionable. Its use results in an undue subsidence of the adjacent earth, thus endangering street surfaces, water and gas mains, as well as the nearby buildings, which are not on rock or hard pan. The walls are usually plumb; the earth or side pressures vary greatly. In very stiff earth with a steep angle of repose, through which rapid progress may be made, little pressure is developed; on the other hand, through ground which offers much resistance to fast sinking and which slides easily, as a wet clay, with boulders, very great pressure may develop, and in addition boulders may roll against the sides of the chambers and cause great damage through excessive pressure. It is very desirable also to have as few braces or bulkheads in the working chambers as possible, as these offer obstruction to rapid work in handling the earth. Therefore, every effort should be made to devise some mode of strengthening the side walls which will give a maximum of strength with a minimum of material used, as well as of obstruction of working space.

The Roof

The Roof.—Here again, various materials have been employed. At one time steel decks for working chambers were used, but in America these soon gave place to wood or a combination of wood and steel. With wood or this combination the work could be begun with much less delay, there being no need to await the seasoning of the masonry, as the wood and steel take all the stresses. The steel walls and deck are not so much used in America, where wood is cheap, and abundant, as in Europe. The deck at one time consisted of a great thickness of squared and dressed timbers, strongly drift-bolted together, alternate layers crossing one another, the under side sheathed with three-inch dressed plank with a caulking groove. The whole inside of the working chamber is usually caulked and tarred to make it practically air-tight. In the case of the Manhattan caisson for the Brooklyn bridge (sunk 1871, 102 ft. x 170 ft.) this deck was 22 ft. thick. This caisson had the underside of the deck sheathed with wrought iron plates to prevent danger or fire, due to the manner of lighting (torches). Soon, however, the thickness of wooden decks was greatly reduced by the use of bulkheads in the working chambers and knee braces underneath, as well as sometimes tying the deck to the cross bracing of the cofferdam above. Since the advent of reinforced concrete an effort has been made to have a well-seasoned portion of this material above the wood, which not only makes a much stronger and more rigid caisson, but also renders it more air-tight, and, moreover, supplies weight—a much needed commodity in such work.

Caisson Deck for Quebec Bridge

It is interesting to compare the thickness of the Brooklyn Bridge caisson deck with that of the Quebec Bridge, 180 ft. x 55 ft., as illustrating recent practice. The latter consisted of two courses of heavy timbers, one longitudinal and one transverse. These were separated by two courses of 3 in. tongue and grooved planks crossed diagonally. Through this deck are placed the following pipes: One small pipe carrying the wires for electric lighting. This pipe is sealed at each end, but has a valve at the bottom end within the working chamber and above the bottom seal. At the top end, beneath the top seal, there is an opening which, when the valve below is opened, emits a loud whistle. This is the means used by those within to signal those without. The return signal is usually given by blows of a hammer on the air-lock. There is also at least one three-inch air pipe (sometimes two) connected by a flexible hose with the air supply, at some point where there is little danger of breaking this supply pipe. When there are not two pipes down through the pier to the working chamber, a second air connection is made to the steel shaft just below the air-lock.

This latter method gives equal safety and equal convenience when the shaft has to be lengthened as the pier is sunk. A pressure gauge and a valve are placed beside each other on the supply lines; these are attended constantly by a gauge tender, whose duty is to regulate the pressure required. The number and size of these connections depend on the size of the caissons and whether the air is or is not to be used to assist in the excavation.

The shaft serves two purposes: First, to take in material and supplies and remove the excavations;

second, to serve as a passageway to the "sand hogs." Small caissons have only one shaft, which serves both purposes; larger caissons have two or more shafts, but unless watched, the workmen use the shafts indiscriminately. As a rule the men in the smaller caissons enter and come out by using the muck bucket. Every shaft for men must have a satisfactory ladder from top to bottom of shaft for emergency and in case of action for damages. It is, however, very seldom—and very reluctantly—that a "sand hog" uses this ladder. At one time the shaft, which is of steel or cast iron, extended from the deck—to which it was securely belted—continuously through the pier to the surface. The shaft varied in size from 3 feet in diameter to a much greater diameter. The lock may occupy any portion of this shaft, as best suits the circumstances. The best practice to-day places the lock at the top of this shaft. This allows the lock tender to remain in the open air. In case of accident to the air supply it allows the "sand hogs" an opportunity to save themselves from drowning, by climbing up the shaft to such a point as to be usually above the water level, or to such a height that the entrapped air, by being compressed by the rising water, may finally counterbalance the hydraulic head.

This metal shafting is so made that it can be collapsed and removed from the piers unless the bottom happened to be caught by the concrete used in sealing the shaft. At one time a short length of metal shaft was always lost. This was later replaced by a wooden form, and to-day the shaft is moulded in the middle of the pier by the use of collapsible wooden forms; the only metal shaft used is at the top and is only long enough to securely attach the lock to the sufficiently seasoned concrete. The shaft may be circular or oval in shape. A narrow vertical strip with parallel faces for joints can be pulled into the shaft, and then the whole shaft may be collapsed and removed. The shafts are in segments, with internal flanges, which are bolted together. The gaskets for the vertical joints are usually ¾-inch hollow rubber tubing, while the gaskets for the circular joints are made of cotton—called lamp wicking by the "sand hogs."

The Lock

The lock may be a portion of the shaft with two doors, both opening toward the working chambers, with by-pass valves, so that the space between may be placed under atmospheric pressure when the outer door may be opened: or under same pressure as the working chamber when the inner door may be opened. The lock is usually somewhat larger than the shaft except when a metal cylinder is being sunk under conditions which demand such a special form, as in underpinning work, when the working space is limited both as to area and head room. The cylinder, which is later to be filled with concrete, may consist of cast iron sections about 5 ft. long by 3 ft. in diameter; the bottom section is the working chamber and the second one is the lock. The cylinder is forced down by jacking against the building, or some other sufficient resistance.

In some large caissons an effort has been made to have a very high working chamber and a very long lock, so as to introduce into the working chamber long timbers to be driven as piles. This method has not had a wide application. It is, I believe, patented by W. H. Patton. The most satisfactory place for the lock is at the top of the shaft and well above the water level, where the lock tender is not under pressure and the clear shaft offers a place of safety for men in case of accident. Locks are usually circular or oval in cross-section, about 5 feet in diameter and from 6 to 7 feet in length; the bottom door leads into the shaft, and the top door may be in the top end or may be in the side.

There have been many styles of doors and locks of more or less efficiency, but the Moran and O'Rourke designs are perhaps as satisfactory as any. The Moran lock requires two attendants, while the O'Rourke lock requires only one. Both are controlled by patents, as are most of the locks possessing any real advantages. The doors are opened by levers on the outside. The connections of the levers to the doors within are made by stuffing-boxes through the skin of the lock. In the majority of locks the derrick cable—handling the material and excavation—goes through the top door of the lock, the hole fitting the cable as closely as possible without doing it any injury. The amount of air escaping is inconsiderable. In the case of the O'Rourke lock there is a stuffing-box on the cable through which the cable moves freely. When the bucket is down the shaft the stuffing-bucket fits in a circular hole in the top door; when the bucket is not down, and the bottom door is open, the hole in the top door is closed by a dummy stuffing-box. The bivalve doors of the O'Rourke lock form a portion of a sphere. All doors in air-locks are fitted with rubber gaskets, ½ in. x 3 in. to 4 in., against which the doors are pressed by the high air pressure inside.

There is one danger which the top doors present which must be carefully guarded against, particularly when the pressure is low—a weight falling upon it may force it open, allowing the caisson to flood. An accident of this kind occurred on a bridge caisson near Jersey City; an empty bucket was dropped and forced open the door. The lock-tender lost his head for a fatal moment and did not close the door again until too late. All the gang below were drowned. If, when a high pressure is in the chamber, the air supply is lost, the working chamber and the shaft very readily fill with sand or clay; and, as a consequence, when once the air excavation has been begun in a caisson the air pressure must be continued till the chamber is filled with concrete.

Cofferdam or Outer Form for Masonry

Here again wood has largely replaced metal; and when a rush job is demanded this outer form is left on, the space between the cofferdam and the shaft being filled as high as need be, or as can be done by concrete, but as this may not be very well seasoned, the cofferdam carries most of the weight used to force down the pier, which sometimes is more than the ultimate load on the pier when the structure is complete. Some prefer to leave the forms on the concrete, as the wood causes less surface friction than the masonry. In all cases the surface should be well coated on the outside with some heavy lubricant. The masonry is built as high as is compatible with safety (say 30 ft.) or as high as the booms will reach before sinking.

If the caisson can be carried to final depth without stopping to lengthen the shaft, and perhaps to place more masonry—an operation requiring tons of weights to be taken off and then replaced—a great saving can be effected. It is, however, rather risky to build small or moderately-sized piers high and then begin to dig the earth from beneath. The pier must be supported on all sides by substantial raker braces, and the excavation must be done very carefully in order to maintain the pier vertical. If the job is not to be completed in an unusually short time the forms are made so that they may be used as frequently as possible.

Economy has demanded that the working chamber, as all other parts, be made as light and cheap as possible. The working chamber walls are now seldom over five feet high; indeed, they are often less, head room being obtained by keeping the excavation well in advance of the cutting edge, or the deck is arched, or both may be done. Tongued and grooved timber, caulked and tarred, is expensive work, so an effort has been made to use light, collapsible wooden or (sometimes) steel forms, which may be removed from the shaft and used again, so that there will be nothing in the pier but steel and concrete. This is a doubtful economy in many cases, particularly when the caisson is large and heavy loads come on the soil, which may cause settlement before the concrete is seasoned, thus endangering the pier. The writer had to design forms for the working chamber for five piers which were each 40 feet square and 2,000 tons in weight. The only part of the pier resting on the soil was the cutting edge, which was 6 inches wide. The supports for the roof forms required to be so designed that the settlement had to be uniform throughout to avoid cracking of the pier. The working chamber had one bulkhead. A hole was left in the bulkhead wall, and also in the working chamber, in order to remove the timber, as it was too long to be sent up the shaft unless cut.

Sinking the Caisson

Let us suppose the working chamber is carefully set in position and built as high as practicable, and has had time to sufficiently set to commence safely the work of sinking. The outside is well greased. One or more frames, about one foot larger than the caissons, are set around it on posts and are strongly braced by raking shores. Properly shaped wedges are placed between the frames and the sides of the caissons. Plumb bobs are suspended to two adjacent faces of the caisson. A man is placed to watch these while men are sent inside to excavate the caisson down as far as possible without air (called "ditching") usually a little below water level. During this preliminary sinking the caisson is brought to the vertical by means of the wedges and braces. Then by means of a level marks are made on the inside of the working chamber so that the "sand hog" may know at all times how the pier stands, and may govern the excavation accordingly. Next, the air connections are made, the light cables are properly connected up, the shaft is put on, and finally the lock, and the air men commence operations. At first the caisson moves down gently, as the earth is excavated; and as the depth increases more weight is needed. This is supplied by piling on cast iron, now in blocks about two and one-half tons in weight, handled by a derrick. At one time in my experience a gang of from fifteen to twenty men were employed continually piling pig iron on top of the caisson. After a time the friction becomes so great that the caisson moves in sudden quick drops of varying dimensions. Here is where the cutting edge or the sides may be injured.

Sometimes, when no more weight can be placed on top and the pier is not to the proper depth, recourse is had to what is called "blowing the caisson." First, the man at the gauge is ordered to open his valve to raise the air by four or five pounds. This causes a flow of air up the outside of the caisson, lessening the frictional resistance. Then, simultaneously, the air supply is cut off and a valve is opened to exhaust the air in the working chamber. The "sand hogs" may, if deemed safe, remain in the chamber, climb the shaft, or come out. When the caisson begins to move the exhaust is shut and the supply opened to prevent flooding of the work chamber.

Proposed Union Station and Tunnel, Montreal

At a luncheon held at Cooper's Restaurant, attended by members of the Montreal Builders' Exchange, on June 7, Mr. F. N. Armstrong explained in detail the proposed central terminal station and tunnel under the St. Lawrence, to be built by the Montreal Central Terminal Company. He pointed out that although Montreal traffic had enormously increased, the railway companies had done nothing in the way of improving their terminal facilities, with the exception of the C.P.R. The proposed line would do away with grade crossings; it was imperative the Grand Trunk crossings should be removed, but the company would not be able to raise the requisite money for some years. The Central Terminal Company was incorporated in 1890 for the purpose of constructing a bridge; their plans were then changed to a tunnel to be used for electrically driven trains. Still later, the present scheme was decided on. Just before the war broke out, Mr. Armstrong had interested English capital in the project, but the conflict put an end to this. He had then visited the United States and had succeeded in obtaining the promise of capital provided that the different railway companies would enter into agreements to use the proposed terminal station. All the companies were favorable, except the C.P.R. and Grand Trunk, who raised various objections.

The station would be built on Lagauchetiere and Vitre Streets, in the centre of Montreal, with the main entrances on those streets. Mr. Armstrong then explained how it was proposed to link up the various lines by means of a short line to be built by the company, giving everyone access to the Union Station. There would, he said be a freight station in the east end of the city, and sorting yards would be constructed. The C.N.R. had under consideration the building of a large station in the city in connection with the Mount Royal tunnel; this would be abandoned and the C.N.R. given access to the Union Station. The Place Viger Station of the C.P.R. would be used only for feight traffic, and the present line of the Grand Trunk as far as St. Henry would be given over to freight, that company coming into the city over the new line of the Terminal Company. Six tracks would be built on this line, while the tunnel would be double-tracked. The entire line would be electrically operated.

The construction of the station would involve the rebuilding of two main and several side streets. The Terminal Company would charge the different companies a rate basis on the extent to which the lines and station were used, but only sufficient to pay certain capital charges and the interest on the capital.

The Union Station would save an immense amount in cartage, would be a great convenience to the general public, would supply a suburban service at a low rate, and give better communication to the south side of the St. Lawrence.

The Montreal Light, Heat and Power Company have issued a new house organ under the title of "Our Magazine."

The Granite Paving Block Industry

A Description of Its Development in Canada—A Bright Future.

By James S. Wilson*

The granite paving sett industry occupies an important position in every country, but perhaps more especially so in Britain, on the Continent of Europe, and in the United States. The European engineer has cautiously, yet amply, experimented with other classes of paving, but during the last ten years or so his experience and energies have been more particularly directed towards improving the granite block. As Canada is a new country, so far as paving is concerned, it may be best in dealing with this subject to compare conditions here with those obtaining in the older countries, analysing their excellent data so that some logical conclusion may be arrived at regarding the merits of this paving and the prospects of the industry here in the future.

During the period of the Roman occupation of Britain, paved roads were constructed for military purposes. Granite rubble was used, consisting of irregular-shaped stones with a level head, the whole being skilfully laid and grouted with a mixture of fine marly clay. In several places, evidence of their handiwork on a fairly extensive scale, and still in an almost perfect state of repair, can be seen. This was possibly the origin of stone paving.

Some two or three centuries ago the manufacturing of granite rubble paving was started in Aberdeen and shipped to the London market. Since that time the Aberdeen granite has practically monopolized this market. The rubble paving was similar to that employed by the Romans on their famous military roads. From this crude beginning has sprung up, by gradual process, the almost perfect Nidger Block paving. The original rubble gave place to the common sett which was from 5 in. to 7 in. on the head and from 9 in. to 15 in. deep, the ordinary sett (called the Belgian Block in the United States), displacing the common sett some sixty or seventy years ago.

Paving Stone of the Future

The most modern form of smooth granite paving consists of blocks from 5 in. to 6 in. on the head and varying in depth from 5 in. to 7 in., with lengths restricted generally to about 12 in., the head joints and sides being nidged or bushed, affording a smooth and perfectly level surface, and permitting of close jointing. During the last few years, the large cities across the water and in the United States have been laying these blocks extensively. While the cost of this class of stone is greater than the ordinary sett, it has not been adopted without undergoing severe tests, and no doubt this will be the paving stone of the future.

In the cities and larger towns of Europe and the United States, granite paving is used extensively because it has been found from experience to be the only paving capable of withstanding the heavy traffic existing in industrial centres. The granite is more widely diffused there, towns are closer together and markets more accessible. The cost of repairing a street, say, in London, Liverpool, Glasgow, New York, or Chicago, is found, from sad experience, to be generally greater than the original cost yard for yard; hence it follows that a paving requiring a minor expenditure in maintenance, even at a greater first cost, is, by far the cheaper in the end. The life of granite is much longer than any other form of paving, which altogether demonstrates the superiority of this material for most purposes.

In Canada, opposite conditions are met with. The granite is principally found in the extreme east and the west. Markets are far away, in consequence of which the cost of granite over the other classes of paving is slightly greater than across the water or in the United States. Does this condition warrant the use of granite in preference to other paving, even having regard to the longer life, lower cost of maintenance, cleanliness, better foothold for horses, etc.? Public paving work in the older countries is generally constructed with funds provided from revenue, here principally by borrowing. As a rule, the life of most forms of paving has been extinguished before the amount borrowed for the work has been paid back. This does not seem sound, as, in effect, it is imposing a debt on the future taxpayer without transferring to him any corresponding advantage; while in the case of a long-lived utility at a not excessive first-cost, with a low annual maintenance expenditure, it is the reverse, the debt being liquidated long before its period of usefulness has expired.

Granite Setts and the Present War

The resources and energies of the military officials on the continent have been taxed to the utmost with enormous transportation difficulties. Excellent as were the continental roads, they were found to be incapable of withstanding the abnormal wear and tear imposed upon them in the huge task of transporting supplies for the armies. The matter was one of vital importance, some expedient had to be devised to meet the critical situation. There could be no question as to what was best. What the British Government official does, he does well; the best had to be provided, and the best was granite blocks. Towns and villages lying on the lines of communication have been or are now being paved with this material.

There can be no doubt of the results or the wisdom and foresight of our famous corps of engineers in their selection, for although other classes of paving could have been executed quicker and cheaper, the well-tested qualities of granite leave no room for questioning the part this paving will play in the ultimate issue of the war.

Although the granites of Canada do not, on the whole, equal in quality the granites of Europe or the United States, there can be no doubt of the existence in this country of fields of splendid granite awaiting development.

The European method of block-making is different to that employed in Canada and the United States. Granite formations there are generally massive, that is, irregularly bedded and jointed, while on the American Continent it is principally sheet formation. This is to our advantage, as the cost of quarrying and working the latter is less than that of the former. Again, blocks are made there, practically in every case, without the aid of power tools, the cutting of the larger pieces being accomplished with either wedges or plug and feathers, the holes being drilled by hand. The mall, or buster, is then used to reduce the block to a

* Sirdar Granite Co., Calgary.

smaller size, the splitting of the block being done with the mall and mash hammer, the latter being again used to nick and knap the mashin (a block from which several paving blocks are obtained) and roughly shape the sett, which is finally finished by a hand hammer, the reel, tiller, or side hammer.

This system applied here would be decidedly unprofitable and wasteful, as it produces a large amount of rough material only suitable for crushing for road macadam and granolithic work; as there is a great demand for these products there, it is a source of profit. Otherwise the stone for crushing would have to be lugged or broken to a suitable size for the cruhsing machine.

Avoid Creation of Useless Stone

In Canada, where we have, so far, little or no market for crushed material, the creation of useless stone must be guarded against and the expense of disposing of same avoided. This is where the more shapely sheet formation is of advantage. The same may be said to hold good in the case of columnal formations in trap rocks, basalts, etc.

The stone supplied to the Canadian cutter is more regular in shape. In addition to the ordinary kit of tools he is supplied with a power drill. Instead of resorting to the uncertain method of splitting with the mall, he makes use of this tool to put in the holes, the more reliable plug and feather being used for cutting. Again, in blocking (knapping), the stone is marked with a tracer which ensures the creation of a block with a good head and arrises on, which requires considerably less finishing than the block turned out by the European sett-maker. The waste stone is reduced to a minimum, quarrying and on-cost charges are lowered, and less plant required. Taking all the circumstances into account, our methods are superior to those practised across the Atlantic, and sufficiently so to offset the higher scale of wages, fuel, etc.

The manufacturing of granite blocks in Canada has been greatly hampered in the past by the lack of experience on the part of the quarry-owner, shortage of skilled labor, and the difficulty of transportation to markets; the latter factor will be rendered easier, of course, as time goes on and the country opens up.

Man has no more difficult problem to face than to profitably win from Nature her resources. To achieve this result, the quarry-master must be a student of Nature, well versed in the handling of stone and possessing a thorough, practical knowledge of the trade.

There are many grades of granite and, while two stones may be composed of practically the same mineral constituents, the qualities of the stone for commercial purposes may vary in the extreme. Even to a skilled and experienced quarry-owner, the selection of a suitable stone presents difficulties. There is no better way to determine the qualities of a granite than by the application of the tools and to do so, one must be able to use them in a workmanlike manner and be able personally to feel, as it is termed, "the way o't."

A disadvantage quarry-owners in the United States and Canada have to contend with is the attitude of municipal authorities calling for tenders for granite for quick delivery, the time allowed for delivery in many cases being less than the time required to manufacture the material. These stones are all made by hand, skilled labor cannot be secured at a moment's notice, the quarry-owner cannot guarantee delivery in time, with the result that all too often the work is executed with other material. There is no need for this state of affairs. In Europe, municipal authorities estimate their yearly requirements at the beginning of the year, when tenders are called for and accepted, and though the material may not be required till much later, it enables the quarry-master to make his plans, and, if he desires, to make and stock the blocks. This ensures a regular supply of labor, keeps the quarry working, and obviates the lack of regular employment which is such a drawback to this country. It further enables the consumer to buy cheaper, to secure better dressed material and assures the timely carrying out of the predetermined paving plans. The dressing of the blocks is of the greatest importance and careful quarry inspection must be made. The rush order is the greatest incentive to bad dressing, and as these orders generally arise from lack of foresight on the part of the municipal authorities, so must the bad dressing be attributed to them. It is the duty of every quarry-master to insist on the production of a first-class block. A good head with well defined arris, full jointed, good bottom and regularity in size should be aimed at. Practical experience has demonstrated the fact that paving cutters will turn out as many blocks when they are compelled to adhere to the specification as when they are allowed more latitude in the dressing. As time goes on, the requirements in this direction are becoming stricter, but while those strictures may seem to hamper the industry for a little, the beneficial and lasting effects to it will become strikingly apparent. Such is the experience in Europe.

Having established from the experience of the older countries the great importance attached to granite block paving, taking into consideration the problem of an ever increasing traffic, with its consequent tear and wear, and the necessity for permanence and durability of construction in our channels of transportation, it seems reasonable to predict a bright future for the granite block industry in Canada.

Longest Life of Any Pavement

With practical quarry-owners, a plentiful supply of skilled labor, a judicious use of power tools and good stone, the cost of production should compare favorably with that of any other country. Being in a position to compete with cheaper and less durable pavings, new markets will be created; smaller towns, which have not hitherto been able to avail themselves of this advantageous form of paving will be enabled to do so; transportation facilities will be increased and taxes reduced. These are very often the determining factors in the choice of a site by industrial concerns, so that the community benefits in general. It is a fact the world over, with few exceptions, that the greater the industrial centre, the greater the use of granite block paving, or inversely, the industrial importance of a town may be determined by the amount of granite paving it has. Granite block has the longest life of any paving; it can be lifted, redressed, and relaid at small cost and made to serve for a second period. Looked at from any aspect, the use of granite block paving will be found to be consistent with sound municipal financing, and, instead of burdening our future citizens with debt, an asset will be created for them. The cheery appearance of the material will beautify and enhance the surroundings, healthier conditions will be obtained, which, in effect, will earn in some measure the appreciation of that human enigma —the taxpayer.

Exciter Sets—The Terry Steam Turbine Co., Hartford, Conn., are distributing a booklet describing and illustrating their duplex exciter sets and enumerating the advantages which are claimed for them.

Grease and Fertilizer from Sewage

A More Economical Method of Sewage Treatment — By-Products Exceedingly Valuable

EXPERIMENTS to determine the feasibility of a new process of sewage treatment invented and patented by George W. Miles, a Boston chemist, were made from 1911 to 1914 under the direction of E. S. Dorr, of the Boston Sewer Department, with results that seem to indicate that it will be not only successful, but profitable. The process is described by Mr. R. S. Weston in a recent article in the Journal of the American Public Health Association, from which we print the following extracts:—

Ordinary sewage sludge from settling basins is greasy, offensive and of so little practical value that farmers will not accept it for fertilizer, even as a gift, yet sewage sludge contains fertilizing elements of great value and considerable grease. The Miles process attempts by the addition of an acid to precipitate the bulk of the solids from sewage in the form of a sludge that can be dried and degreased, thereby producing a readily saleable and greaseless fertilizer, as well as recovering the valuable grease. Either sulphuric acid or sulphurous acid may be used, and the process contemplates the manufacture of the acid at the disposal works. If sulphuric acid were chosen, ordinary weak chamber acid of 1.53 specific gravity would be used, but the cheapest source of acid is undoubtedly pyrite (native FeS_2), which when roasted in a furnace of proper construction produces sulphur dioxide (SO_2). This is a gas that may be fed directly into the sewage, in which it would dissolve, forming sulphurous acid.

The addition of sulphur dioxide precipitates most of the grease, together with the greater part of the suspended matter. The resulting sludge is dried, extracted with a solvent to recover the grease, and the remainder prepared for fertilizer. An important sanitary feature of the treatment is that the sulphur dioxide is a strong disinfectant, so that the acidified sewage contains few bacteria. It also contains but little suspended matter. Consequently, the supernatant liquid may be discharged into a body of water without producing any nuisance.

The experiments, which were conducted by officers of the sewer division of the city of Boston, consisted of 11 runs, involving the treatment of about 26,000 gallons of sewage. From these experiments it was concluded that from 1,000,000 gallons of sewage 1,738 pounds of dried sludge would be obtained and that it would contain 21.7 per cent. of grease, which at 4c. a pound would yield $15.08. In addition, there would be 13.61 pounds of fertilizer base, estimated according to agricultural standards to be worth $9.25, making the total value of the recoverable material about $24.33 per 1,000,000 gallons.

The results of Mr. Dorr's experiments were so promising that their repetition under the supervision of impartial investigators and for a longer period was thought worth while, and arrangements were made for a week's study of the process under the supervision of the sanitary-research laboratory of the Massachusetts Institute of Technology. These further experiments were begun on July 7, 1915, and were made under the direction of Robert Spurr Weston, with Prof. W. T. Sedgwick in consultation. The results obtained were checked by further experiments, covering three days, which began on November 8, 1915, so that the tests covered both warm and cold-weather conditions. The close agreement between the results of the two sets of experiments is remarkable, and it may be definitely stated that the experiments of the sanitary-research laboratory confirm the results obtained by Mr. Dorr regarding the amount of sludge that may be recovered from Boston sewage and the amount of grease that is present therein. The Miles acid process has thus been shown to possess many advantages as a method of sewage disposal for cities like Boston, namely:

Has Many Advantages

1. It disinfects the sewage by reducing the numbers of bacteria from millions to hundreds per cubic centimeter.

2. If the drying of the sludge and the extraction of the grease can be accomplished economically, it is probable that a large part, if not all, of the cost of the acid treatment may be met by the sale of the grease and fertilizer recovered from the sewage.

3. The use of so strong a deodorizer and disinfectant as sulphur dioxide would prevent the usual nuisance of treatment works. The experiments have shown that the sludge can be held at the works for four days during the heated season without giving offensive odors, while the effluent is inoffensive and stable enough to be discharged into Boston Harbor without the slightest probability of creating a nuisance.

4. The addition of sulphur dioxide to the sewage also avoids any fly nuisance, which is a handicap to the operation of Imhoff tanks and trickling filters.

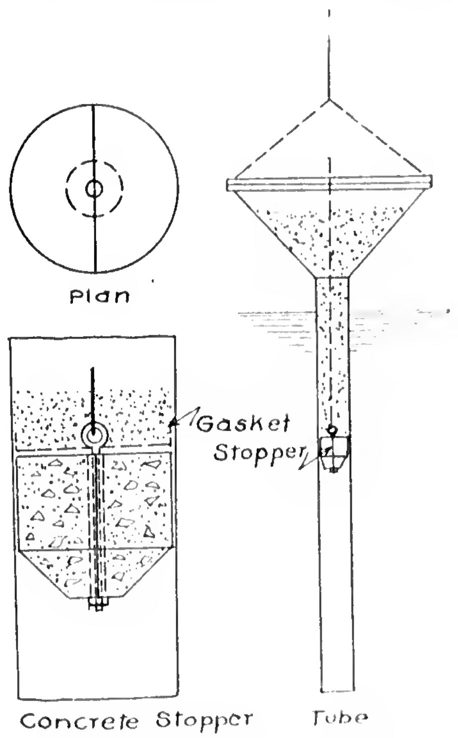
Drying of the sludge and the extraction of the grease are absolutely essential for the success of the process. Mr. Dorr's figures, which show profits of from $6 to $11 per 1,000,000 gallons, appear high, and it is possible that he has allowed too little for the acid and for the cost of drying the sludge; but even if his figures be doubled, the process is still well worthy of consideration by the city of Boston, because of its freedom from nuisance, as it produces an effluent which is practically free from disease germs and which can be discharged into the harbor with impunity.

With the facts at hand, the process would be very satisfactory for Boston from a sanitary standpoint and is more promising economically than any other known. The value of Imhoff tank sludge is hardly enough to pay for the drying. At Milwaukee, Chief Engineer Hatton estimates the total value of activated sludge at from $9 to $15 per 1,000,000 gallons, while our Boston experiments have proved that the sludge from the Miles process, although less in bulk than that from the activated-sludge process, has a value of more than $24 per 1,000,000 gallons of sewage. Correcting Mr. Dorr's estimates for the higher amounts of acid which these experiments show to be necessary, one gets $18 per 1,000,000 gallons as the average cost of treatment, and $6 as the margin of profit.

Placing Concrete Under Water

The subaqueous deposition of concrete is often a matter of extreme importance; it is also extremely difficult. The "tremie" method of deposition of concrete, so that it shall not suffer from the water, has been used to good advantage on some large and important works in recent years. Briefly, the tremie is an apparatus for depositing or consolidating concrete under water, consisting essentially of a steel or wood tube with a hopper top.

In order to secure the best results, that is, a good quality of concrete and a proper flow through the tube during operations, a considerable amount of preliminary investigation is usually necessary to determine the size of tremie and the method of handling it. Experiments seem to indicate that a 15-in. diameter tube



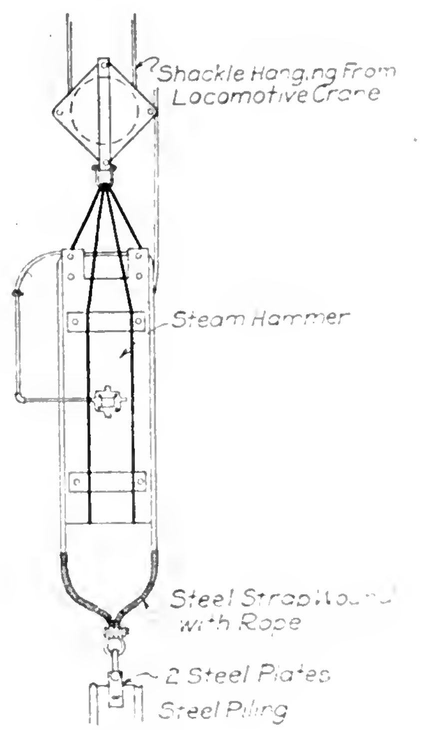
Apparatus for Placing Concrete Under Water.

gives about the best results. It gives about the right amount of friction. A 12-in. tube gives too much friction, while an 18-in. tube gives too little, often allowing a charge to be lost. There are three general points on which care should be exercised in the operation of a tremie. The first is the tendency of the concrete to choke up the tremie tube. When this occurs it causes delays and disturbs the concrete already in position. It may be overcome generally by the use of a rather wet mix with small stoning and by holding the tube high enough to start the charge moving just as the hopper starts to fill instead of after it is full. The second is with the onrush of water into the tube as the last of the charge is pouring out. The lowering of the pipe to stop the flow must be started in time so that the pipe will be completely sealed. It should be lowered gently so as not to disturb the concrete already deposited. The regulation of the speed and the proper movement for giving this signal to the hoisting engineer, are matters requiring considerable practice on the part of the men. Third, the concrete should pass through as little water as possible between the tube and the freshly deposited concrete, as otherwise a considerable portion is lost.

In depositing subaqueous concrete by a tremie the use of some sort of wadding or stopper is essential for the first filling of the tube. Various materials have been used for stoppers, such as cement sacks, shavings, paper bags and sawdust. This material is usually inserted in the top of the tube, and as the concrete is added the stopper descends the tube driving out the water until the tube is full of concrete. The difficulty, however, is that this foreign substance becomes imbedded in the deposited concrete, which is particularly objectionable if the column is at all high and of narrow cross section. To overcome this difficulty, a concrete stopper has been designed, as shown in the cut.

Pulling Sheet Steel Piling with a Steam Hammer

Pulling sheet steel piling with the hammer they were driven with in half the time required to drive them is a rather new kink in the contracting business. The hammer is inverted and fitted with a close fitting steel yoke provided at both ends with a clevice. One of these is connected with the hoisting tackle of a derrick which is kept under constant strain, and the other to the pile. The hammer weighs about 3,000



Pulling Sheet Piling with Steam Hammer.

lbs., strikes 75 blows per minute and operates either by compressed air or steam from the hoisting derrick.

Piles that take an average of three minutes to drive can, as a rule, be pulled in one and a half minutes by this method. The device has permitted the salvage of piles which might otherwise, owing to the cost of pulling, have been left in the ground.

M. Beatty & Sons, Limited, Welland, Ont., have recently been awarded contract by the Dominion Bridge Company for two 9 x 12 link motion hoisting engines with cut steel gears, and two 60 in. x 156 in. vertical boilers built under Ontario inspection, for use on the Intercolonial Railway Car Ferry Terminals at Carleton Point, P. E. I., and Cape Tormentine, N. S.

Progress on St. Maurice River Dam

GOOD progress is reported on the St. Maurice River dam being constructed for the Quebec Streams Commission by the St. Maurice Construction Company (contracts sublet to Fraser, Brace & Company). The dam site is in entirely unsettled country, 37½ miles, in an air line, north of the division point, Parent, on the National Transcontinental Railway, and 45 miles from the junction of the Manuan and St. Maurice rivers.

Designs and preliminary work have been completed for the construction of this 1,720 ft. concrete dam and the creation of the huge storage reservoir. Some 160 billion cubic feet of water will be stored, making a flow of 12,345 second feet for 150 days or 7,372 second ft. for 300 days. This storage will allow for the regulation of the flow of the St. Maurice River, so that some 168,000 h.p. more is available as steady power at three points below. The important powers benefitted are Shawinigan (82,000 h.p. at present, 164,000 h.p. future); Grand'Mere (41,000 h.p. present, 82,000 h.p. future); La Tuque (32,300 h.p. present, 78,000 h.p. future).

Largest Reservoir, etc.

This reservoir will be the largest on the American continent. The dam for the reservoir is not an unusual structure, but the project is of timely interest more from the magnitude of the flooded area than from any particular features in the construction of the dam. The preparation of plans for the dam was instructed by J. W. Thurso, with Edward Wegmann and J. M. McCarty as consulting engineers. The investigations in the field and the design were under the direction of O. Lefebvre as chief engineer.

Test borings showed solid rock underlying the site. The plain gravity type of dam was selected, with sliding gates and the profile was fixed after assuming an ice pressure of 50,000 lbs. per lineal foot, acting at the pressure level of the overflow weir; foundation uplift was neglected. The dam is to be 1,720 feet long, of four straight sections, with 851 feet of spillway. The notable features of the dam are a movable sluice for logs and rubbish, 375-foot measuring weir, and means of heating the gate chambers.

The work is of particular interest due to the fact that the dam site is situated 50 miles by route north of the National Transcontinental Railway, necessitating extensive transportation facilities. The contractors had a choice of two routes for reaching the place of work. A route from Parent was investigated and found to offer a line of easy grades and curves, but through country so badly burnt that there was not enough timber in it to provide the ties. The second route was adopted by the contractors, utilizing river transportation for 30 miles on the St. Maurice River above Manuan as far as Chaudiere Rapids, a railroad 20 miles in length being required from Chaudiere to the dam site at La Loutre.

River transportation is carried out by large scows hauled by gasoline motors. The river, throughout the 30 miles that have to be navigated, is very crooked, with a large number of sand bars. The current averages about 2½ miles per hour at ordinary stages of water. The scows are from 15 to 25 tons capacity, 10 ft. wide and from 60 to 75 ft. long. They are easily steered by a 50-foot oar in the hands of one man and guided very readily even in the crookedest parts of the river. Indian pilots who know the river are employed to steer the boats and the trip between Manuan and Chaudiere averages about five hours going up and three hours coming down. Transportation difficulties will be understood when one realizes that some 25,000 tons of material have to be transported to the dam site.

Next to the problem of providing transportation to the dam site is the problem of unwatering the dam foundations. The river is divided into two channels at the dam site, one on the west side of a small island, 350 feet wide, and the other on the east side, about 120 feet. The plan is to close the small channel first, build a cofferdam across the main or west channel high enough to force the water to pass over the dam in the small east channel during the entire construction of the dam in the west channel. The west channel part will contain ten sluice gates and when this part has been completed these will be opened and the section of the dam in the east channel will be carried to the proper height.

The quantity of excavation at the dam site is comparatively small, being about 700,000 cubic yards of rock and 14,000 cubic yards of earth. The amount of masonry in the dam will be about 70,000 cubic yards. A suitable quarry has been located within a thousand feet of the dam site which will supply stone for the concrete. The rock from the quarry will be dug with a steam shovel and dumped directly into a large crusher. A combination mixing and crushing plant is located on a steep hillside very close to the dam and will furnish material directly to it. Concrete forms, stones, machinery, etc., will be handled by two overhead cable ways and four derricks standing on cribs on the downstream side of the dam. A sawmill has been erected at the dam site and about 4,250,000 board measure of timber has been cut during the winter and delivered, in booms, at the dam site. All lumber required for erection purposes will be sawed at the plant. Oil burning locomotives will be used on standard gauge tracks, to eliminate the danger of fire in the woods along the right of way.

Hydro-Electric Power for Construction

A hydro-electric plant of 1,150 h.p. is being erected by the contractors to furnish power for the construction work. The location selected is the La Loutre Rapids, 2¼ miles below the dam site. The machines to be installed have two 39-in. wicket-gate wheels per unit, each unit to furnish 575 b.h.p. at 150 r.p.m. with a net head of 15 ft. The generators are 350 kv.a., three-phase, 2,400 volt, 60-cycle alternators with 14 kw., 125 volt exciters mounted on the main shafts.

The power house is being built of reinforced concrete and extends as a dam across a small channel of the river between two islands. Another channel is used as a spillway. The whole structure sits on solid rock, the draft tube and tailrace being excavated behind cofferdams built in November last year. This plant is practically ready for operation.

New Companies

The Sherwood Construction Company, Limited, Toronto, Ont., have been granted a charter.

The Montreal Forge & Shackle Company, manufacturers of metal, Montreal, Que., have registered.

Filtration Plant, St. Hyacinthe

The city of St. Hyacinthe, P.Q., with a population of about 15,000, will this year give further proof of its progressiveness by the installation of a mechanical filtration plant, to provide a plentiful supply of wholesome water to its citizens. At the same time additions to the pumping equipment will greatly improve the supply, both for domestic and fire service.

Present System

The present pumping equipment for domestic service consists of two centrifugal motor driven pumps, each having a capacity of 1¼ million gallons per day against a pressure of about 60 pounds per sq. in.

Fire service of about 120 pounds per sq. in. is obtained by operating these two pumps in series and by an additional centrifugal pump, which, operating against a pressure of 120 pounds per sq. in., has a capacity of 1¼ million gallons per day.

In addition to these three pumps, there is held in reserve a Holly steam pump, which is capable of supplying two million gallons per day, either for domestic or fire service. All pumps obtain their supply from the Yamaska River by means of a single 20-inch cast iron suction pipe, and discharge directly into the force mains supplying the city. There is no storage tank or reservoir connected with the system.

Proposed System

By the plans for the new work, water from the Yamaska River will reach the pumping station through two cast iron suction pipes, and will be lifted to the coagulation basins by four centrifugal pumps, each having a capacity of two million gallons per day. After passing through the coagulation basins, filters and filtered water reservoir, the water again returns to the pumping station.

A new two million gallon per day pump, in addition to the two existing domestic service pumps and the Holly steam pump, will supply filtered water for domestic service up to a maximum capacity of 6½ million gallons per day.

For fire service there will be installed a new four million gallons per day pump which, with the existing fire service centrifugal pump and the Holly steam pump, will supply water at 120 pounds pressure per square inch up to a maximum rate of 7¼ million gallons per day.

Coagulation Basins

Two coagulation basins are contemplated, with a combined capacity of 400,000 gallons. Each basin is 66 ft. x 32 ft. 3 in., inside measurements, and is of concrete construction throughout. These basins are entirely underground, with 2½ feet of earth fill over the reinforced concrete roof. Suitable provision is made for the regulation and control of the flow of water through the basins.

Filtered Water Reservoir

The filtered water reservoir, which is also of concrete construction and entirely underground, is 60 ft. x 39 ft., inside measurements, and has a capacity of 193,000 gallons. With an extension, proposed under a separate item, the reservoir will have a total capacity of 260,000 gallons. At one corner of the reservoir is a pump from which the pump suctions receive their supply of filtered water.

Filters

Four filter units, each with a nominal daily output of one million gallons, are located directly above and supported by the roof of the filtered water reservoir. The filters are located, two on each side of an operating and pipe gallery, which contains all piping and other equipment necessary for a modern installation.

Buildings

The filter building is 49 ft. 8 in. x 67 ft. 8 in., outside measurements, and encloses the filters, operating gallery, and a passage leading to the headhouse. The headhouse is located between, and connected with, the filter building and the existing pumping station. The lower floor is reserved for storage and chemicals. The upper floor contains the office, laboratory, and chemical room.

All buildings have brick walls and wooden roofs, and conform in style and architecture and other particulars, to the existing buildings. Windows are large and numerous, to make the interiors light and attractive. Electric lighting and steam heating systems are provided for in the contract.

Miscellaneous Equipment

The plans and specifications for the work include all piping and drainage systems and miscellaneous equipment, including wash water pump, blower, strainer, and air systems, controllers, operating tables, coagulant apparatus, chlorine apparatus, etc., required to make the plant complete and ready for service.

The work will be done under the general direction of Mr. Rene Morin, Mayor, and Mr. T. A. St. Germain, President of the Aqueduct Committee. Plans and filtration engineer.

Adjustable Shore

The cut shows a handy, light, adjustable shore, that can be readily built and should prove useful to contractors in supporting forms for concrete work. It consists of a pipe with timber extensions. On the top of the pipe is bolted a guide which runs between the

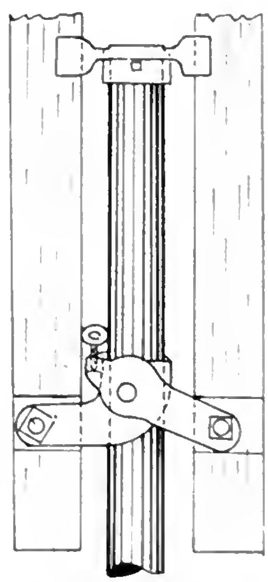


Diagram of Adjustable Shore.

2 x 4 in. extensions; at the lower extensions a self-locking plant is bolted. The shore is raised to the required height and when the weight is applied the clamps grip the pipe, the heavier the load, the tighter the grip. The thumbscrew lock prevents the shore from slipping.

Road Maintenance

Now that extensive road building is progressing in all parts of the Dominion, it might not be out of place to reiterate a few words concerning road maintenance. This problem is closely related to the movement for the construction of good roads, but the regrettable feature of the movement is that, as a rule, no provision is made for the upkeep of the roads after their construction. The result is, all too frequently, that many admirable highways have, after a few years, fallen into such a state of dilapidation that to repair means practically to reconstruct them.

The question of maintenance, as it is now understood, is of comparatively recent origin. It owes its inception, along with the good roads movement, to the advent of heavy and speedy motor traffic. With the roads of pre-motor times, subjected only to the action of slow and light traffic, the maintenance problem was of more or less secondary importance, but when the automobile appeared as a factor, the resulting rapid wear demanded urgent consideration of the question. Although from year to year it has been brought more forcibly to bear on the attention of the people, there has seemed to be a disinclination to meet it or to supply the funds necessary for effectively carrying it out.

Motor traffic, in entirely recasting the standard of road building, has imposed more solid and expensive construction which, in turn, has necessitated more costly upkeep. And not only is deterioration due to normal wear, but it also takes place from weathering conditions, such as action of frost, spring floods, and deterioration of the bituminous coating

The present poor condition of many roads is due to a failure to realize that road maintenance must begin where road construction leaves off, so that no wear will have a chance to get a grip. The old adage "a stitch in time saves nine" applies with special aptness to road maintenance. It means constant and vigilant care to counteract the effect of traffic or weather. In many cases authorities seem to feel that their duty has ended when a highway passes out of the hands of the contractor, and they fail to provide sufficient funds or labor to keep the road in its proper original condition.

County and municipal officials and engineers are now realizing more and more the extent of their duties. They are beginning to feel that it pays to maintain rather than re-surface or entirely reconstruct their roads every few years. In some municipalities the more solid concrete or brick pavements are being considered which, although higher in first cost, reduce maintenance charges to a minimum.

The method and cost of road upkeep depends on the nature of the road and its condition, and the work must be so carried out as to ensure the most effective treatment in each individual instance. In most cases, careful repair of all ruts, holes and surface breaks, is all that is necessary, with an application of a surface binder at sufficient intervals. Even the common surface application, crude oil, when applied immediately upon completion of a road renders it less pervious to the wearing effects of heavy traffic.

The question that municipalities must consider when formulating their good roads schemes is that the money spent will be of little avail unless they are prepared to back it up by a sufficient outlay to maintain their highways as permanent works from year to year. They must realize that maintenance is equally as important as the original construction and that only by effective maintenance can they realize the full value of a good road system.

Mainly Constructional

East and West—From Coast to Coast

The new C. P. R. depot at North Toronto has just been opened to the travelling public.

During the month of May, 21 building permits were issued in the city of Moncton, N. B., representing a value of $28,175.

The total amount of the building permits issued during the month of May this year in Chatham, Ont., was $28,350, as compared with $24,735 in May, 1915.

Building permits to the value of $144,441 were issued during the month of May this year in the city of Halifax, N. S., as compared with $113,270 for May, 1915.

A. R. C. Clark has been awarded the contract for the construction of the N. B. Telephone Company's new exchange at West St. John. It will cost about $12,000.

Letters Patent of incorporation have been issued to Westman Hardware, Limited, the capital of the company being $40,000. Their head office will be at London, Ont.

The foundry at Beauceville, Que., which recently came under the management of Messrs. Marcoux and Poirier, has been destroyed by fire, resulting in an estimated loss of $12,000.

The St. Mary's River Construction Company, Limited, has been incorporated, with a capital of $25,000, to carry on the business of general contractors, head office at Sault Ste. Marie, Ont.

The Royal Connaught Hotel, which has just recently been completed in Hamilton, Ont., has now thrown its doors open to the public. It is considered one of the most modernly equipped hotels in the Dominion.

Mr. J. D. Buckley is erecting a large refuse burner at his French Fort Cove mill, near Newcastle, N. B. It will be 110 feet high and 32 feet in diameter at the base. The contractors are Mooney & Sons, of St. John. The burner will cost about $7,000.

The Regina Builders' Exchange at a recent meeting passed a unanimous resolution not to accede to the demands of the Bricklayers' Union that the hours of labor be 9 hours per day, except on Saturdays, when work would cease at 1 p.m., and the rate be 75c. per hour.

The Nova Scotia Construction Company, who were awarded the contract for the completion of the forty-mile section of the Valley Railway between Gagetown and Westfield, have sublet the contract in ten mile sections to Kennedy & McDonall, Poupore Bros., Lynch & Gorman, and Smith and Merrithew.

The tender of the Dominion Bridge Company for the superstructure of the Pretoria Avenue bridge in the city of Ottawa, $84,158, has been accepted by the city council. Owing to the rapid rise in the price of steel, this amount is much above the original estimate. The work on the bridge will occupy about 18 months.

Several towns along the line between Borden and North Battleford, in the Province of Saskatchewan, are endeavoring to obtain the right of way between those two points, a distance of 60 miles, for the construction of a highway, the object being eventually to extend this road and make a great highway from Saskatoon to North Battleford.

The Dominion Textile Company, Limited, of Montreal, have sold its buildings and real estate in Moncton to the biscuit manufacturing firm of J. A. Marven Limited. The Textile Company is removing the cotton machinery from the main building, after which the Marven firm will fit it up for biscuit manufacturing on a more extended scale.

Work on the Centre Street bridge in Calgary, Alta., is progressing satisfactorily. Three of the spans have now been completed, and the men are now at work finishing the ornamental towers which will rise at either end of the centre span. The fourth, and southernmost, will not be constructed until the last possible danger of spring floods is over.

A bill to grant to the Dominion Government the strip of land necessary for the construction of the Banff-Windemere highway was passed recently by the legislature of the Province of British Columbia. This road will be about 40 miles long and will cost about $200,000. The Dominion Government have agreed to complete and maintain the road.

Judge Demers has confirmed the appointment of engineering arbitrators in the litigation between the city of Montreal and the Harris Construction Company. This has reference to work done for the city, the amount involved being nearly $100,000. Mr. H. E. Vautelet will represent the city, Mr. Emile Vanier, the contractors. Dr. L. A. Herdt is the third engineer appointed by the court.

During the month of May this year there were 217 building permits issued in the city of Winnipeg, Man., representing a value of $395,700, as compared with 218 last year, representing a value of $135,000. The total for the first five months of the year is $1,135,400, as compared with $640,150 in 1915. There are also extensive building operations going on this month, including Stovel's new building, $160,000.

In connection with the work on the St. Maurice River dam in the Province of Quebec, several camps have been constructed on a large area of land cleared at the site for that purpose. In order to facilitate navigation on the river for the transportation of material, a temporary dam is under construction at Manouan. A telephone line from Manouan to the scene of operations, a distance of 32 miles, has also been installed.

Kane & Ring, contractors, have been awarded the contract for the construction of permanent sidewalks in the Fairville district of St. John County. About 20,000 feet of sidewalks will be laid. Fairville is developing rapidly, both as an industrial and residential district. The completion of the new highway bridge at the Falls and the promise of an improved water service have given a considerable impetus to its development.

Three tentative sites for the proposed grain elevator to be erected in the place of the I. C. R. St. John, N.B., elevator destroyed in 1914, have been submitted to the city council by general manager Gutelius, of the Canadian Government Railways, to make a selection from. One site is just south of the custom house; the other two are adjacent to the sugar refinery. The council has held two meetings on the subject, but has not reached a decision.

The council of Bassano, Alta., have threatened to take steps to force the city of Calgary to install a sewage disposal plant in order to protect the water for their use. It appears that Calgary received instruction from the government to proceed with such a plant some time ago, but the declaration of war caused delay. The city engineer, however, has now been instructed to prepare a report in this connection, and the construction of the plant is to commence when the war is over. It will cost about $300,000.

Owing mainly to the diversion of men to ammunition plants there is an acute shortage of unskilled labor in Montreal which is affecting the building trade. Combined with this cause is the internment of aliens, the recruiting, the calling up of men by the warring nations, and the small immigration. The labor agencies are able to supply only a very small portion of the needed labor. At a meeting of the directors of the Builders' Exchange it was stated that one quarry company which offered good wages, free transportation, constant work and sleeping accommodation, had not been able to obtain 25 men to go a short distance out of town.

Building permits to the amount of $24,570 were issued in Medicine Hat, Alta., during the month of May. Amongst these is included a building for the Alberta Foundry and Machine Company, $20,000, which will be built of brick and steel. It will have a frontage of 160 feet and a depth of 120 feet, and will include foundry, machine shop and offices. It will be heated by steam and supplied with electric power and lighting. The new building will be put up over the present plant, in order to avoid any interference with the progress of work, and after completion the old shops will be taken down. The permits for May, 1915, only amounted to $2,510.

Following a tour of inspection of the Toronto Harbor work, in which Hon. Dr. Reid, acting Minister of Public Works; the Harbor Commission, the City Council and a number of members of the Board of Trade participated, the chairman of the Commission, Mr. Lionel H. Clarke, made the announcement that a saving of over $1,000,000 was being made in connection with the reclamation of Ashbridge's Bay and the establishment of an industrial area there. In this area between two and three hundred acres have been reclaimed which practically completes the work. The estimated cost of this operation was $5,000,000, but according to Mr. Clarke's statement the actual expenditure will not reach $4,000,000. The chairman also mentioned the fact that during the last twelve months the Commission has increased the harbor property by 230 acres by acquisition from the Government, the C. P. R. and the Grand Trunk.

While in the city of St. John, N.B., recently, Mr. H. P. Timmerman, industrial commissioner of the C. P. R., announced that his company had engaged the well-known U. S. engineering firm of Arthur D. Little to take up research work on lands adjacent to the C. P. R. track in Canada. The object of these researches will be to ascertain the commercial values of ores or other mineral or chemical deposits that may be discovered contiguous to the railway, and which might form the basis of industrial enterprises. It frequently happens that discoveries of such natural resources are made by men who either do not appreciate their value, or who lack the capital to test them commercially. This work will be taken up by Mr. Little's research department and the information secured will form the basis for bulletins that will be issued by the company from time to time. Mr. Little is an ex-president of the American Chemical Society.

Personal

Company Sergeant-Major Armstrong has been killed in the recent fighting. He was a graduate in science of McGill University. Prior to joining the forces he was on the engineering staff of the city of Montreal.

Mr. E. L. Cousins, who has been engineer to the Toronto Harbor Commission, has just been promoted to the position of general manager, a reorganization of the office staff having been made necessary by the enlistment of Major Alex. Lewis, who had acted as secretary since the inception of the Commission.

Capt. Frank P. Adams, of the 186th overseas battalion, who for several years has been city engineer of Chatham, Ont., was recently honoured, on the occasion of his departure for the training camp at London, by the city councils of 1913-14-15-16, under whose direction he served. He was presented with a purse of gold, and members of the respective councils made brief addresses complimenting him on the efficiency and courtesy which he had always shown and the very satisfactory service he had rendered the city.

Contracts Department

News of Special Interest to Contractors, Engineers, Manufacturers and Dealers in Building Supplies

Waterworks, Sewerage and Roadways

North Bay, Ont.
The Town Engineer, H. J. McAuslan, will receive tenders until noon, June 28th, for the construction of about 50,000 square feet of sidewalks.

Norwich, Ont.
The Town Council propose to lay about 40,000 square feet of brick pavement on concrete foundation. Clerk, William Fairley.

Pembroke, Ont.
The Town Council are having plans prepared for permanent pavements, estimated to cost $4,000. Engineer, W. J. Moore.

Quebec, Que.
The City Council are considering the paving of Sauvageau and Aqueduc Hills, at an approximate cost of $5,300. Engineer, W. D. Baillarge.

St. Hyacinthe, Que.
A by-law has been passed providing for the construction of paving estimated to cost $25,000, and for a quantity of side walk. Engineer, H. Cadieux.

Toronto, Ont.
Commissioner of Works R. C. Harris has recommended the construction of asphalt paving to cost about $36,665, and bitulithic to cost $13,074.

Victoria, B.C.
The City Council propose to lay a watermain to the premises of the Esquimalt Waterworks Company. Estimated cost, $5,000. Engineer, C. H. Rust.

CONTRACTS AWARDED

Markham, Ont.
The Town Council have awarded the contract for the construction of a gravity main and collecting basin to Murphy & Barnes, 23 Temple Avenue, and the contract for supply of pipe to the National Iron Company, Toronto.

Ottawa, Ont.
The City Council have awarded contracts to the Union Construction Company, Bank Street Chambers, for the construction of asphalt pavement on Napean and Albert Streets, estimated to cost $41,160.

Quebec, Que.
The City Council have let the following contracts: asphalt paving on St. Foye Road, Quebec Paving & Construction Company, 70 Tenth Avenue, Limoilou; scoria block on Henderson, Ramsay, and Orleans Place, George Madden, 822 St. Valier Street; scoria block and granite block on Bridge Street, partly to George Madden and Quebec Paving & Construction Company; roemac on St. Olivier Street, G. Michaud, 90 Des Forges Street.

St. Catharines, Ont.
The City Council have awarded a contract for construction of a trunk sewer to John Maguire & Son, Spadina Road, Toronto. Estimated cost, $64,589.

Welland, Ont.
The contract for construction of a sewer on Burgar Street has been awarded to Louis Sacco. Approximate cost, $3,520. Contractor requires 6, 8 and 10-inch pipe.

Railroads, Bridges and Wharves

McNab Township, Ont.
Plans have been prepared by J. T. Morris, Pembroke, for a bridge to be built over the Madawaska River for the Township and Renfrew County Council. Estimated cost, $10,000.

Toronto, Ont.
The Toronto Harbor Commissioners have had plans pdepared for a steel bascule bridge to be constructed across the Don Diversional Channel at the foot of Cherry Street. Chief Engineer, E. L. Cousins, 50 Bay Street.

CONTRACTS AWARDED

Arden, Man.
The municipalities of Lansdowne and Langford have awarded the contract for construction of a concrete bridge to the Brown Construction Company, 302 Tribune Building, Winnipeg. Approximate cost, $5,500.

New Brunswick Province.
The Provincial Department of Public Works have awarded to W. R. Fawcett, Sackville, contracts for the contsruction of the Nicholas River bridge and for new substructure and general repairs to Upper Sackville and Anderson bridges. Approximate total cost, $41,000.

South Dumfries Township, Ont.
The contract for steel work required in the construction of a bridge over Maniwarring Creek for the Township Council has been let to Hamilton Bridge Works Company, Ltd., Bay Street North, Hamilton, at $2,100, and abutments to Bain & Ross, Embro, at $958.

Upper Jemseg, N.B.
The Department of Public Works, Fredericton, have awarded the contract for construction of substructure and approaches of a steel truss bridge to Joseph McVay & Sons, St. Stephen, N. B. Approximate amount of contract, $20,000.

Public Buildings, Churches and Schools

Anderdon Township, Ont.
Plans of a school are being prepared for the Trustees of School Section No. 6 by Jacques & Company, Boug Building, Windsor. Frame construction. Estimated cost, $5,000.

Beeton, Ont.
Bulk or separate tenders on the erection of a school will be received until June 30th by the Secretary to the School Board, J. N. Lannin. Approximate cost, $15,000. Architect, John Wilson, Collingwood. Plans with the Secretary, the Architect, and at office of the Contract Record, 347 Adelaide Street West, Toronto.

Cainsville, Ont.
Tenders on the erection of a church for the Baptist Congregation will be received until June 24th by the Architect, L. D. Barber, Temple Building, Brantford. Brick construction. Approximate cost, $6,000.

Calgary, Alta.
The Congregation of Central Methodist Church propose to replace their building, recently destroyed by fire, with a new structure to cost about $40,000, and to instal an organ at an approximate cost of $15,000. Nothing definite is yet decided.

Eganville, Ont.
The Evangelical Lutheran Congregation are building a church under supervision of R. G. Reinke. Frame construction, venecred with concrete block. Approximate cost, $12,000. Architect, Bruno Michel, Carleton Place, Ont.

Halifax, N.S.
The Board of School Commissioners propose to build a school on Morris Street, and plans will be prepared by W. J. Buash, 60 Bedford Road. Cost will probably exceed $120,000.

Hamilton, Ont.
F. W. Warren, Bank of Hamilton Building, is preparing plans for an Interdenominational Church, estimated to cost $9,000. Tenders will be called shortly. Cut stone, steel, and brick construction.

McGregor, Ont.
The Catholic School Trustees will call for tenders on the erection of an addition to the school, estimated to cost $5,000. Frame construction. Particulars from Father J. A. Pinsonneault.

Mindemoya, Ont.
The Methodist Congregation are about to start work on the erection of a Church, estimated to cost $3,000. Stone construction. Chairman of Building Committee, D. Wyman.

Montreal, Que.
The Commissioners of St. Gregoire le Thaumaturge will receive tenders until June 26th for the erection of a school, estimated to cost $250,000. Architect, C. Bernier, 70 St. James Street.

New Liskeard, Ont.
The School Board propose to build a school at an approximate cost of $30,000. Town Clerk, J. I. Dixon.

Ottawa, Ont.
Tenders on the erection of a laundry and dormitory for the Grey Nuns of the Cross will be received until June 26th. Plans at the Hospital or at office of the Architect, Charles Brodeur, 63 City Hall Street, Hull, Que. Approximate cost, $50,000.

Otterville, Ont.
The Township of South Norwich propose to build a Library, and have been promised a grant of $6,000 by the Car-

negie Corporation. Clerk, Alexander Macfarlane.

Peace River, Alta.
The Department of Public Works, Ottawa, have prepared plans for an Immigration Hall, estimated to cost $5,000. Frame construction. Secretary, R. C. Desrochers, Ottawa.

Peterborough, Ont.
Tenders on steel valley trusses for the roofing of St. James Methodist Church are being received by the Secretary to the Building Committee, A. E. Prest, 242 Lansdowne Street.

Port Colborne, Ont.
Tenders are now being received for the erection of St. James Church, according to revised plans. Architect, C. M. Borter, Niagara Falls, Ont. Estimated cost, $18,000.

Sudbury, Ont.
Tenders on all trades required in the erection of a school on College Street will be received until June 30th by the Architect, V. L. Morgan, Wilson-Greenwood Block. Plans and specifications with the Architect, and at office of MacLean Daily Reports, Ltd., 25 Charlotte Street, Toronto.

Timmins, Ont.
Ellis & Ellis, Architects, Manning Chambers, Toronto, are preparing plans for a school, estimated to cost $40,000. Hollow tile and brick construction.

Toronto, Ont.
A site in Queen's Park has been purchased for the erection of new premises for St. Michael's College, St. Joseph Street. Stone construction. Approximate cost, $350,000. Registrar, Rev. Father H. Carr.

The Board of Education have cancelled the contract for plastering at the Park School, and are now receiving new tenders. Plans and specifications at office of the Superintendent of Buildings.

Weston, Ont.
Tenders on the erection of a hospital cottage for the National Sanitarium Association are now being received by the Architect, C. S. Cobb, 71 Bay Street, Toronto. Brick construction. Approximate cost, $6,000.

Wiarton, Ont.
Tenders will be received until June 29th for the erection of an addition to the High School, installation of a lavatory system and construction of a sewer. Plans and specifications with the Secretary to the High School Board, W. M. Newman, and the Architects, Forster & Clark, 887 Second Avenue E., Owen Sound.

CONTRACTS AWARDED

Berlin, Ont.
The contract for steel work required in the erection of a Polish Roman Catholic Church has been awarded to the Dominion Bridge Company, 20 Victoria Street, Toronto, and the masonry to Wunder Brothers, 20 Peter Street.

Chatham Township, Ont.
The general contract for the erection of a school for Union School Section No. 15 has been let to Chester McGregor, Wallaceburg. Brick construction. Approximate cost, $3,950.

Hamilton, Ont.
The contract for supply of seating required for the Robert Land School has been let to the Globe Furniture Company, Shantz Avenue, Waterloo.

The contract for masonry required in alterations to Christ's Church Cathedral has been awarded to Mitchell & Riddell, 46 Head Street. Approximate cost, $15,000. Architects, Stewart & Witton, 7 Hughson Street.

Leamington, Ont.
The County Council have awarded the contract for remodelling the House of Refuge to A. E. Law, Leamington, on a 10 per cent. basis. Estimated cost of work, $5,000.

Mount St. Patrick, Ont.
Work has been started on the erection of a convent for the Roman Catholic Congregation. The contract for masonry and brick veneering has been let to Anthony Coulas, Springton Post Office. Frame and brick veneer construction. Approximate cost, $6,000.

North Vancouver, B.C.
The following contracts have been let for work required in the erection of an addition to the North Lonsdale School: plastering, A. Clarke; tinsmithing, G. Johanson; painting, C. Musson; electrical work, W. Graves; heating and plumbing, J. Young; carpentry by day labor.

Orillia, Ont.
The contract for heating and plumbing required in the erection of the Municipal Building, has been awarded to E. A. Latimer, West Street.

Oyen, Alta.
The Trustees of School Section No. 3058 have awarded the general contract for the erection of a school to the Alberta School Supply Company, 10125 104th Street, Edmonton. Brick construction. Approximate cost, $5,500.

Quebec, Que.
The Protestant School Board have let the contract for repairs to the Desjardins School to Emile Cote, 360 Richelieu Street. Estimated cost, $3,000.

The general contract for interior repairs to the chapel of Fabrique Notre Dame, 16 Buade Street, has been let to C. E. Morissette, Ltd., 208 Latourelle Street. Approximate cost, $3,000.

Sacre Coeur, Que.
The general contract for repairs to the Parish Church has been let to Charles Belanger, St. Simon Street. Approximate cost, $4,000.

Sault Ste. Marie, Ont.
The general contract for alterations and additions to the Furse Business College has been awarded to McPhail & Wright, Sault Ste. Marie. Estimated cost, $7,000.

St. Michel, Que.
The general contract for the erection of a Presbytery for the Parish has been let to W. Beauchamp, 1559 Bordeaux Street, Montreal. Approximate cost, $8,500.

Toronto, Ont.
The contract for brick work required in the erection of Boon Avenue Baptist Church has been awarded to F. & A. E. Ham, 83 Salem Avenue, and carpentry to A. C. Smithers, 121 Greenlaw Avenue. Tenders on plumbing and tinsmithing are now being received by carpentry contractor.

The Board of Education have let the contract for plastering at Dovercourt School to William Gayton, 31 Malvern Avenue, at $3,999.

Windsor, Ont.
In connection with the erection of an addition to the College, the contract for supply of 85,000 red vitrized face brick has been let to the Chick Contracting Company, McDougal Street, at $18 per thousand, and a contract for buff brick at $19.

Winnipeg, Man.
The contract for repairs to the Point Douglas Presbyterian Church has been awarded to the Sutherland Construction Company, 206 Carlton Building, on a percentage basis. Approximate cost, $4,000.

The contract for the erection of a Church for St. George Anglican Congregation has been awarded to Claydon Brothers, Furby Place. Frame construction. Approximate cost, $7,500. Architects, J. D. Atchison & Company, 914 Boyd Building.

Business Buildings and Industrial Plants

Auburn, Ont.
E. Helwig is considering the erection of a store and residence on Main Street, at an approximate cost of $3,000. Frame and white brick construction.

Chatham, Ont.
Tenders on the erection of a factory for the American Textile Company will be called about the end of the month by the Architects, Adams & Adams, Market Building. Brick construction. Approximate cost, $30,000.

Chicoutimi, Que.
A Lapointe is about to build a store and residence, estimated to cost $4,000. Brick construction.

Cobden, Ont.
Walter Stitt, Cobden Post Office, has commenced the erection of a store on Main Street, estimated to cost $4,000. Brick construction.

L'Islet, Que.
J. A. Dionne is remodelling his store and residence. Estimated cost, $12,000.

Moncton, N.B.
The Atlantic Underwear Company, Ltd., are building an addition to their premises, under the supervision of R. C. Donald. Estimated cost, $6,000.

Montreal, Que.
The Canadian Northern Railway, St. James Street, have commenced the erection of a freight shed on Stadacona Street, estimated to cost $3,000.

Norwich, Ont.
M. L. Bushell has commenced the erection of an office and residence, estimated to cost $3,000. Brick construction.

Ottawa, Ont.
Work has been started by A. D. Hudon, Clarkstown, Ont., on the erection of stores and residence, estimated to cost $8,000. Tenders are being received for the smaller trades. Brick veneer construction.

Quebec, Que.
The Premier Feature Film Company of Canada, St Bridhe Street, propose to build a studio, and have secured a site. Brick and stucco construction. Approximate cost, $50,000.

Revelstoke, B.C.
The Farmers' Co-operative Association are considering the erection of a creamery, estimated to cost $3,000.

Simcoe, Ont.
William Tilley, Architect, Temple

Tenders and For Sale Department

Tenders Wanted

Sealed bulk and separate tenders addressed to the undersigned will be received up till five p.m., **June twenty-fourth, 1916**, for the several works required for the erection of a new School Building in Selkirk, Ontario. Each tender must be accompanied by a certified cheque for ten per cent. of the amount of tender, which will be forfeited should the contractor refuse to sign contract and complete the same.

Plans and specifications may be seen at the office of the undersigned or at the office of the Architect, A. W. Peene, 107 Clyde Block, Hamilton, Ontario. The lowest or any tender not necessarily accepted.

J. E. HOOVER, Sec.-Treas.,
Box 18, Selkirk, Ont.

June 1st, 1916. 23-25

Extension of Time

TENDERS

Sealed tenders will be received up to 6 p.m. of **Thursday, June 22, 1916**, by the Secretary, for the erection and completion of a six-room school building to be built in Parry Sound, Ont., for the Parry Sound Public School Board.

Plans and specifications may be seen at the office of the Secretary-Treasurer, Parry Sound, Ont.; the office of the Contract Record, 347 Adelaide Street West, Toronto, Ont., and at the office of the Architects, Angus & Angus, Angus Block, North Bay, Ont.

The successful contractor will be required to furnish a satisfactory guarantee.

The lowest or any tender not necessarily accepted.

J. D. BROUGHTON,
Sec-Treas., Parry Sound Public School Board,
21-25 Parry Sound, Ont.

Sealed tenders, addressed to the undersigned, and endorsed "Tender for Supplying Coal for the Dominion Buildings," will be received at this office until 4 p.m. on **Wednesday, June 28, 1916**, for the supply of coal for the Public Buildings throughout the Dominion.

Combined specification and form of tender can be obtained at this Department and on application to the caretakers of the different Dominion Buildings.

Persons tendering are notified that tenders will not be considered unless made on the printed forms supplied, and signed with their actual signatures.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so or fail to complete the contract. If the tender be not accepted the cheque will be returned.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, June 7, 1916.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department. 24-25

Tenders addressed to the undersigned will be received by registered post only up to noon on **Tuesday, July 4th, 1916**, for the supplying of

ONE 3 H.P. PHASE MOTOR; ONE 20-INCH SQUARE BASE SELF-FEED VERTICAL DRILL WITH ¾-INCH DRILL CHUCK AND SHAFTING.

Samples of the several articles can be seen and forms of tender obtained upon application at the office of the Fire Department, Adelaide Street Fire Hall, Toronto. The usual conditions relative to tendering as prescribed by city by-law must be strictly complied with or the tender will not be entertained. The lowest or any tender not necessarily accepted.

T. L. CHURCH, Mayor,
25-25 Chairman, Board of Control.

Tenders Wanted

Sealed tenders will be received up to noon on **Monday, July 10th, 1916**, for the construction of a Municipal Drain in the Township of Minto, known as Municipal Drain No. 7, approximately **12,411** feet long.

Plans, profiles and specifications can be seen at the office of C. D. Bowman, O.L.S., West Montrose, or at the office of the undersigned, to whom the tenders must be addressed.

A marked cheque for the sum of $150 must accompany each tender as a guarantee of good faith. The lowest or any tender not necessarily accepted.

W. D. McLELLAN,
Clerk of Minto,
Harriston, Ont.

Harriston, June 19th, 1916. 25-27

CANADIAN GOVERNMENT RAILWAYS

TENDERS

Sealed tenders, addressed to J. W. Pugsley, Secretary, Department of Railways & Canals, Ottawa, Ont., and marked on the outside "Tender for Elevator Foundations, Transcona," will be received up to and including twelve o'clock noon, **Tuesday, July the 4th, 1916**, for the construction of reinforced concrete foundations on wood piles or concrete piles, for 1,000,000 bushel storage capacity Grain Elevator. Working Houses and Track Shed at Transcona, Manitoba; separate tenders to be submitted for the foundations with concrete piles and foundations with wooden piles, and tenders may be submitted on either or both designs.

Plans, specifications and blank form of contract may be seen at the office of the Chief Engineer of the Department of Railways & Canals, Ottawa; at the office of the Chief Engineer, Moncton, N.B.; at the office of the General Superintendent, Winnipeg, Manitoba; at the office of the Resident Engineer, Fort William, Ont.; and at the office of the J. S. Metcalf Company, Limited, Engineers, Montreal, P.Q.

All the conditions of the Specifications and contract form must be complied with.

Tenders must be put in on the blank form of tender, which may be obtained from any of the offices at which plans are on exhibition. Each tender must be accompanied by a certified bank cheque, payable to the Honorable the Minister of Railways & Canals, for the sum of $15,000.

The lowest of any tender not necessarily accepted.

F. P. GUTELIUS,
General Manager
Canadian Government Railways.

Dated at Moncton, N. B.,
June 17th, 1916. 25-26

Hydro Tenders Wanted

Sealed tenders, marked "Tenders for Extension to Front Street Sub-Station," and addressed to the Chairman, Toronto Electric Commissioners, will be received until noon of **Wednesday, June 28th**. Tenders will be considered from the various trades, also bulk tenders for the entire work. Tenderers wanting sets of plans must make a deposit of $10, which will be refunded after plans have been returned.

Plans, specifications and form of tender may be obtained at Engineering Office, corner Duncan and Nelson Streets. The lowest or any tender not necessarily accepted. 25-25

TENDERS

Tenders will be received until **Friday, June 30th, 1916**, by the undersigned, for all trades required in the erection and completion of a new Public School Building in College Street, Sudbury, Ontario. Plans may be seen and all information obtained at the office of the Architect, Victor L. Morgan, Wilson-Greenwood Block, Cedar Street, Sudbury, Ontario.

All tenders are to be sent in by Registered Mail and plainly marked on the outside, "Tender for new Public School, Sudbury," and must be accompanied by marked cheque for 5 per cent. of the amount of the tender.

The Board reserves the right to reject any or all tenders submitted.

The Sudbury Public School Board,
25-25 Per Joseph Fowler, Secretary.

Sealed tenders, addressed to the undersigned, and endorsed "Tender for Examining Warehouse, Toronto, Ont.," will be received at this office until 4 p.m. on **Monday, July 17, 1916**, for the construction of the building mentioned.

Plans, specification and form of contract can be seen and forms of tender obtained at the office of Mr. Thos. A. Hastings, Clerk of Works, Postal Station "F," Yonge Street, Toronto, Ont., Mr. R. L. Deschamps, Central Post Office, Montreal, P. Q., and at this Department.

Persons tendering are notified that tenders will not be considered unless made on the forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, June 16, 1916.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department. 25-26

Tenders for Debentures

Sealed tenders will be received by the undersigned up to 8 o'clock p.m. on **June 27th, 1916**, for the purchase of $15,000 6 per cent. Debentures of the Corporation of the Village of Elmira, under By-law No. 366. No tender necessarily accepted.

J. H. RUPPEL,
Clerk.

24-25

Tenders for 4-in. Stop Valves

Tenders will be received by registered post only, addressed to the Chairman, Board of Control, City Hall, Toronto, up to 12 o'clock noon on **Tuesday, July 4th, 1916**, for the supply and delivery of:

4-in. Stop Valves for High Level Pumping Station. Tender No. 48.

Envelopes containing tenders must be plainly marked on the outside as to contents. Specifications and forms of tender may be obtained at the Works Department, Room 12, City Hall. Tenders must comply strictly with conditions of City By-laws as to deposits and sureties, as set out in specifications and forms of tender. The lowest or any tender not necessarily accepted.

T. L. CHURCH, Mayor,
Chairman, Board of Control.

25-25

Board of Education

Sealed tenders, whole or separate, addressed to the Secretary-Treasurer of the Board of Education, will be received until

Thursday, June 29th, 1916

for

Midsummer Repairs, Sundry Schools in the following trades:

Roofing, Tinsmithing, Iron Stairs, Exterior Painting, Plumbing, Steam Fitting, Electrical Work, Cabinet Work, Local Telephones, Tinsmith's Stoves and Furnace Work.

Specifications may be seen and all information obtained at the office of the Superintendent of Buildings, City Hall, Toronto. Each tender must be accompanied with an accepted bank cheque for five per cent. of the amount of tender or its equivalent in cash, applying to said tender only. Sureties for all tenders exceeding four thousand dollars must be furnished by Surety Companies. Tenders must be in the hands of the Secretary-Treasurer at his office in the City Hall, **not later than 4 o'clock** on the day named, after which no tender will be received. The lowest or any tender will not necessarily be accepted.

MILES VOKES,
Chairman of Property Committee
W. C. WILKINSON,
Secretary-Treasurer.

Distant Fields Look Green

There is very convincing evidence to show that the Canadian people as a whole are firm advocates of the old adage, "No prophet is respected in his own country." At any rate they practice this principle persistently, humiliating themselves and their own prophets before the prophets of other nations and, what is even more to the point in this commercial age, paying out good gold for a product which is obtainable in the home market of a quality, as has been repeatedly shown, in no way inferior to the foreign article. Why do we do it?

This is an age of advertising. The manufactured product that is not advertised is simply not used. So with a man. Canadian professional men, however, are not advertisers, and especially does this apply to engineers, who, almost without exception, are modest, retiring, and diffident of extolling their own virtues before the general public. This does not apply in the same degree to engineers of other countries and especially to those of that country with which we come most frequently into competition.

* * *

The local professional man in every walk of life, too, labors under the disadvantage of living down every little mistake he has made. We leave our old doctor because he has made a slight error in judgment and call in a new one of whom we know nothing, and who, likely enough, has just been dismissed by our neighbor for a more serious matter. So with engineers. We know all the mistakes our home engineers have made. They have been talked about in the daily papers, magnified by ignorance and prejudice, reiterated in season and out, until we lack the moral courage to employ anyone in the public blacklist, even if we ourselves have not lost faith in them. And so along comes an outside engineer, headquarters in New York or Chicago; we've never heard anything against him—because we've never heard anything of him before; but he comes highly recommended—by his friends—and the native engineer is out of the running. No search is made of the foreigner's credentials, no list is sought of his mistakes and failures—he's taken at face value—without question. The foreign fields look green, chiefly because they are far away.

* * *

This pernicious habit of Canadian organizations of various sorts would be humiliating, even if it were necessary, but it is rendered many times more so by the fact that we have as good men right here at home as may be found anywhere in the whole world. Their one weakness may be that they lack the wider experience of some of the outsiders, but what they lose in this way is more than made up by a closer knowledge of local conditions, a keener appreciation of local requirements, and a greater pride in local work. One has not to seek far to locate instances of failure of foreign engineers to make good, owing to lack of interest in the work—inspection is scant and infrequent, the responsibilities are given over to underlings who do not measure up to requirements, local conditions and requirements are miscalculated. Then, too, there is frequently a suspicion of a sort of supercilious attitude towards the little Canadian bits of work, such as a $15,000,000 aqueduct, which leads the engineer to take a chance. Sometimes he, too, makes a miss—all of which the Canadian consumer pays for in gold.

* * *

The amount of work, building and construction of every sort at present under way in Canada and being architected or engineered by other than Canadians, is simply tremendous. Either the authorities who pass over the claims of home talent and employ foreigners are wrong or our local men are incompetent. We have no hesitation in urging that there is no trace of truth in the latter alternative. It follows, then, that the blame must be placed with those in authority who employ the foreign architects and engineers—thus laying themselves open to charges of ignorance of the facts, disloyalty to their country and fellow-citizens, and entire lack of appreciation of the value of building up our reputation as a producer of men quite as much as of manufactured products.

Where is the remedy? It probably depends chiefly on the sound common sense of our municipal and other authorities, but surely the engineer himself can do something to assert his rights. What seems to be the most urgent need is that those who buy "service" should become seized of the fact that this product is "made in Canada," and that it stands ready to compete with any similar product made anywhere else. Our professional men, in this sense, then, are manufacturers, and, as such, are surely justified in much more aggressive publicity. Canada has the resources —must we admit we have not got the men to develop them?

Engineers and Architects

The activities of the architect and the structural engineer are related in many respects. In large modern buildings there is a tendency to consider not only the design from a purely engineering standpoint, but also to regard its architectural effects and its relation in a general scheme of city planning and improvements. The same applies to bridge construction, where the bare and ugly structures are being abandoned for the more ornamental and more graceful designs, but quite as correct from every engineering standpoint. This has called forth from the structural engineer his best efforts to cope with the problems of ornamental and architectural art. Engineers as a whole realize their lack of knowledge of the rudiments of architectural design and this has meant the cooperation of architects and engineers in the planning of these ornamental structures. This has a disadvantage, possibly, in that it creates a tendency for each to unduly emphasize his own share in the work and real co-operation is often lacking. There is a call for a person combining the abilities of both architect and engineer, and by slight readjustment, engineering schools should be able to supply this lack. Heretofore, they have not, as a rule, striven to sufficiently broaden their courses, but by the exercise of judicious care in the elimination of old and substitution of new subjects, there is here an opportunity for giving engineering students such an insight into the fundamentals of art and architectural design as will fit them for such work of this nature as they will come in contact with.

Waterbound Macadam Suitable for Heavy Traffic

That waterbound macadam, if properly surfaced—and this can be done economically—will stand up well under heavy motor traffic is illustrated by experience in the Bronx district of New York city, which maintains 1,800,000 square yards of this pavement at a cost as low as 2 3/5 cents per square yard in one heavy traffic street and 3 1/5 cents per square yard in other streets. The method of maintenance is described in a current issue of the Engineering Record:—

The most striking example is the Grand Concourse and Boulevard. This pavement, which is 4½ miles long, has two 35-ft. roadways and contains 192,000 square yards of surface. According to an informal count, it has carried as many as 1,200 vehicles in an hour. It is a main driveway, leading to the parkways and suburban counties to the north, and carries regularly a heavy, and, at times, high speed traffic. Heavy trucks frequent it. Though the proportion of this class of traffic is not large as compared to other streets in the Bronx, it does amount to more than the average hard-surfaced country road has to carry.

The original surface treatment of the Concourse consisted of a ¼-inch thickness of Tarvia A and grit. The tar treatment was applied hot in the proportion of 1/3 gallon to the square yard by a squegee, though the highway officials state that if they had to do it over again they would use a pressure distributor. The cost of the first application was 8 cents per square yard, due to the fact that it was thoroughly cleaned and the dust film entirely removed before the bituminous material was applied. The extreme thoroughness of the cleaning as considered justified in order to secure a satisfactory bond between the metal of the road and the bituminous surface.

Every spring a gang goes over the roadway and using tar, makes whatever patches may be required. When the warm weather comes a paint coat of Tarvia B and grit is applied. This is the only maintenance on the road throughout the year. The aim is to keep the top surface thin.

The maintenance on other waterbound streets in the borough is similar to that on the Concourse. Some of them do not require repairs annually, but are sometimes allowed to go over until the next spring. Those on a grade appear to require less repair than those under similar traffic on level stretches. The quantity of bituminous material applied varies from 1/6 to ¼ of a gallon per square yard, according as the appearance of the road indicates the need of a greater or less quantity.

Million Dollar Sugar Factory

The sugar factory now being constructed at Chatham, Ont., for the Dominion Sugar Company, will be one of that city's largest and finest industries. It will cost over one million dollars and will include eight buildings of fireproof construction, brick, steel, and concrete being the materials used. The site will cover some 64 acres of land. At the present time there are considerably over 200 men employed in the construction, which will require the use of approximately three million brick, 1,200 tons of constructional steel, and 10,000 cubic yards of concrete, and there will also be laid about ten miles of piping. The large smoke stack of the factory, 175 feet high, has been completed, and the steel frame work of the main building is now nearly finished. This building will be 5 storeys high, 320 feet by 140 feet, and when completed, will handle 1,500 tons of sugar beets daily. Other buildings will be the beet sheds, 456 feet x 300 feet; the raw sugar warehouse, 300 feet x 70 feet; the sugar warehouse, 200 feet x 140 feet, and the pulp drier and warehouse, 142 feet x 152 feet, which will have a capacity for drying between 90 and 100 tons per day. The equipment of the factory will be the most modern in every respect, and waste will be practically eliminated. For this purpose a barium will be erected, one of the most important additions to modern sugar plants. This is for the further treatment of the material which passes through the main building, which was formerly discarded as waste, but which can now be turned into sugar by this new process. There will also be a machine shop for making repairs to the factory equipment, and a boiler house, 175 feet x 50 feet, which will contain 12 large boilers with a 4,000 h.p. capacity. In connection with the shipping facilities, 10 railway spurs will run into the plant, and soundings have been taken for the construction of a dock along the water front, which will be about 650 feet long. There will be a storage capacity in the yards and flumes of 50,000 tons.

Signs with which country merchants adorn bridges on rural roads in attempts at advertising, are under the ban of the state highway commission of Minnesota. State aid will be withheld from all counties failing to cause removal of signs.

Relation between Engineers and Contractors

The Successful Contractor of Today has Technical as well as Practical Knowledge — Some Suggestions on the Wording of Agreements

By J. W Rollins *

THE engineer and contractor of the present day are both technical men— the one designing the work and then superintending its construction; the other working out the best method for doing the work and then carrying out the actual construction under the direction of the engineer.

This relation has materially changed in the last few years owing to the great development in modern engineering. In the old days when the work was done mainly by hand labor the engineer was "boss" in many ways, and the successful contractor was the one who could drive his men to the limit, but who had no technical knowledge and in many cases no education, but was guided by that greatest of all gifts, "common sense." He looked up to the engineer as his superior and expected from him such instruction and direction as was necessary to keep him out of trouble.

To-day, however, the situation is entirely changed, and the contractor is often obliged to have more technical knowledge in order to execute work than the engineer who designs it.

It is not a difficult proposition for an engineer to draw a plan showing a foundation for a bridge in water 100 feet deep, possibly in a swift current and in the midst of navigation; or to show a subway 50 feet below heavy buildings in a crowded thoroughfare, under the surface of which may be an electric conduit of 20,000 or 30,000 volts, large water mains under 200 pounds pressure, steam pipes with 500 pounds of live steam, added to sewers, telephone and telegraph lines without number and possibly electric conduits for street car traffic; but to construct such work successfully requires a contractor with great technical skill and knowledge, a man with great resources and strong nerves to meet all the troubles which may arise.

Not Size So Much as Skill

The writer heard Colonel Goethals, of Panama, make this statement: "The people think the Panama Canal is a great engineering feat, but it isn't a particularly great work of that kind, but rather a job of handling a great amount of material; and as an engineering proposition the Panama Canal does not compare with the work done on the New York subways."

When the engineer gives out contracts for work of this kind he should have confidence in the contractors who will do the work; and in turn, the contractors should have full confidence in the engineer. That is, to get the best results there must be the heartiest co-operation between the man planning the work and the man doing it.

The medium between the contractor and the engineer is of course the contract and specification, and to these matters I would ask your particular attention.

A contract has been defined as "a meeting of the minds of the contracting parties," and with this one definition in mind, I think the engineers and contractors could easily settle their disputes, if they could keep the lawyers out of the case. But they can not, and the result is that most engineering contracts have many clauses which are most unjust to the contractors, who, by signing them, give up almost their "birthright."

That a contract in its terms should comply with the definition before given, "a meeting of the minds of the contracting parties," its terms should be so plain and explicit— as free as possible from legal verbage— that any contractor of reasonable intelligence should understand what he is agreeing to do, when he signs the contract.

It should be assumed that when a contract has been awarded, the contractor expects to do the work called for in accord with the terms of the contract and specifications, and to make a profit on his work; that the engineer also expects to have his work done as he has specified, and if so done is willing to have the contractor make his profit. That is, he will do justice to his clients or employers by getting the work done well, and to the contractor in seeing that he is paid justly for what he has done.

The lawyers are responsible for some of the objectionable clauses in contracts, particularly the "blanket" clauses, so called, which hold the contractor responsible for everything that might happen, whether through his fault or negligence or through the fault or negligence of other parties.

Meaningless Contracts

There are often many terms and conditions in a contract, of which neither party knows the meaning, and often the lawyers who put in all the blind, blanket clauses make them so blind that their true meaning has to be settled by the courts.

Here is one of those legal clauses which the writer is certain never originated in the brain of an engineer:

"The said contractors hereby declare and agree that they shall be accountable for the full performance of this contract, and by signing hereof admit that the said plans, elevations, sections, specifications and parts before referred to are sufficient for their intended purpose of doing the said work, and that the work can be successfully executed in accordance therewith, without any additional or extra work other than that set forth thereby or necessarily inferred to be done from the general nature and tendency of the plans, drawings and specifications aforesaid, upon a fair and liberal construction thereof."

This apparently innocent clause which at the time was looked upon as one of a lawyer's ideas of a proper contract and was not expected to be understood by the contractors, cost us $10,000, and a railroad company an equal amount. We agreed to build the masonry for two abutments and a pier for a railroad bridge across a river. The plans showed the two abutments directly behind the old ones with a clearance of about two feet at the foundation lines. The abutments were 30 feet high and when the excavation got down to the footings it developed that the old masonry projected into the line of the new work, so that a cofferdam could not be driven to get the new foundation in. It so happened that the bridge was in a mill pond, so that by drawing the water off on Sundays we finally got the bottom in.

* President of Holbrook, Cabot & Rollins Corporation, Engineers and Contractors, Boston, before the Engineers' Society of Western Pennsylvania

We also got into trouble with the pier, which was on piles with concrete deposited under water for a foundation. The piles were driven and the concrete deposited, and after a week or so an examination of this concrete showed it had not "set." We waited another week, then a month, and finally tried to pump the cofferdam out, with the result that the bottom "blew up," showing the concrete worthless.

Tests were made of the cement—I think it was "Lehigh," and it proved to be all right—but in making tests using the river water the samples would simply "slump," and seven different brands showed the same result. Tests of the water showed it to be polluted by mills above the bridge so that the cement was ruined.

We had to drive a 6-inch dam under the bridge girders at an enormous expense, pump the dam out, deposit the concrete in the dry, and then build the pier.

Meanwhile we were discussing with vigor the matter with the engineers—finally at the completion of the work making a claim for extra pay on account of the conditions developed during construction.

Guaranteeing Work

Our attorneys, however, called our attention to the clause in the contract above read, whereby we had practically "guaranteed" that the work could be done according to plans and that we would not make any legal claims for variations.

The railroad people were fair in the matter and paid half the loss, which we were glad to get in face of the adverse legal opinion given us by our own counsel. But such a clause, in the opinion of the writer, is an absolutely unjust one.

There are other clauses and conditions for which, in the opinion of the writer, the engineer is responsible, and which completely nullify the drawings and general specifications and make absolutely indefinite the amount of work to be done.

For instance:—

"Excavations shall be made of dimensions indicated upon plans, where dimensions are given, **or as otherwise directed.**"

"Piles shall not be driven below elevation 102 and shall be cut off at these levels **unless otherwise directed.**"

Also the clause which allows the engineer to make changes in the line, grade, plan, form, dimensions or materials of the work, with no allowance made for extra payment, when conditions vary.

Anyone can readily see what abuse an engineer could make with these clauses where the contract might be for deep water work, as was the contract from which these were taken; thereby compelling the contractor to go to any depth inside cofferdams with his excavation and pile work.

Disclaims All Responsibility

Another clause, and one which is also general, disclaims all responsibility of information furnished, and in some cases of quantities of work to be done.

Inasmuch as the Supreme Court of the United States has held that borings shown on plans must be taken as the basis of the contract for such items as are covered by them, it would seem that this decision would be broad enough to cover all information given.

And why shouldn't information given be held as the basis of the contract. The engineer spends months in making plans and estimates and getting information upon which to base them. This information is, in the judgment of the engineer, correct, and on his part is the basis of the contract, and on this information the minds of the contracting parties "meet."' It is an impracticability for a contractor to spend the time and money to investigate conditions of a contract as thoroughly as the engineer does, and he doesn't do it, although the contract says he must from his own knowledge make his bid.

So when conditions change, why should not the conditions be met, in a man to man fashion, and paid for in full justice to both parties. This is a vicious clause, one which causes much trouble and which should be eliminated from all contracts.

As to the matter of guaranteeing quantities: This is often a difficult matter, for unless investigations are very complete it is almost impossible to make even approximate estimates.

It generally does not hurt a contractor to have quantities increased, but may cause trouble to have them materially decreased, for this reason: On some jobs there is a large overhead, general and plant expense, and this expense in an itemized bid must be divided up amongst the items, and we generally try to add this expense to the items which are fixed or may be increased, but if some of these items are decreased these general expenses will not get paid for.

The writer is of the opinion that where quantities are given, even as "approximate," the courts have held that they must not vary more than 20 per cent. either way, and if they exceed this variation may be subject to additional payment if this variation causes loss to the contractor.

Here is another clause:—

"The Directors reserve the right to suspend the whole or any part of the work herein contracted to be done, if they shall deem it for the interest of the Commonwealth so to do, without compensation to the contractor for such suspension, other than extending the time for completing the work as much as it may have been delayed by such suspension."

Two or three years ago we took a contract to build a railroad in New England in an inaccessible country, and spent $300,000 in plant, equipment and in getting it onto the line of work. About this time came the crash in New England railroads, and we expected to be ordered to stop work. We were not, however, although there was a "stop clause" in our contract; and if trouble had come, where do you think we would have "gotten off?"

Doing Impossibilities

There is always much discussion as to clauses which for their execution call for what practically is an impossibility, and as to whether they can be enforced, or compel the contractor to pay the penalty. A recent opinion of the court on the question of executing an impossibility:—

"There can be no question that a party may, by an absolute contract, bind himself to perform things which subsequently become impossible, where the event which caused the impossibility might have been anticipated and guarded against in the contract, or where the impossibility arises from the act of default of the promisor. . . . But where the event is of such a character that it cannot be reasonably supposed to have been in the contemplation of the contracting parties, when the contract was made, they will not be held bound by general words, which though large enough to include, were not used with reference to the possibility of the particular emergency which afterwards happens."

We have had some sad experiences with this impossibility clause. On a certain contract for an intake for an electric power development, we had to build a sea wall, and the plans showed 6-inch hard pine sheeting driven to a depth of 20 feet below mean low water. The specifications said, "sheet piling should be driven as shown on plan," and no borings were taken and no information given as to the material through which the material was to be driven, although the general character of the soil was sand. This line of sheeting was to act as a permanent bulkhead, and would be of no value if not driven without crippling or deforming the timber.

Before we got ready to begin our work, other construction immediately adjoining us was undertaken by driving similar sheeting for a deep trench, though through no depth of soil, with no success, the timber being badly crippled and broken. We called these conditions to the attention of the engineer, but with no results, so we began our work, but could not drive the sheeting, though we tried every contrivance known, with heavy water jets and steam hammers. Finally the engineer admitted we could not drive the sheeting satisfactorily and the plan was changed by dredging out most of the sand and gravel, driving the sheeting and refilling the dredged area.

Before this was done, however, we made the "impossibility" plea, but were told that the company's lawyers wouldn't listen to it, that we had agreed to do the work according to the plans, and that if necessary to get the sheeting down to grade we should bore holes in the gravel or rock, if there, and stick the timber in these holes.

Another condition common to contracts, which we object to, is the one under which the engineer can design a structure and give the exact instructions under which the work is done, or require the approval of the engineer to a design submitted by the contractor, and yet disclaim all responsibility for the results. The principles in law on this matter have been pretty well settled by the courts. A decision of the Supreme Court of the United States has settled the fact that an engineer designing a structure and directing in full the construction, must assume the responsibility for its fulfilment of its functions.

The Engineer's Responsibility

For instance, although a contract states that a contractor must guarantee a waterproofing job, if the engineer prescribes the method of construction and supervises the work as done, this guarantee cannot be enforced. A notable instance of this was developed in the construction of the Charlestown Navy Yard dry dock at Boston. The construction of this dry dock required a cofferdam of great strength, although of not very great length; the excavation going down to 40 feet or more below low water. The contractors for the work were men skilled in water construction, and submitted a plan of cofferdam to the engineer in charge of the work; and this plan was objected to as lacking in strength, and the plan returned to the contractors. A second plan submitted by the contractors was similar to the first, but showed great detail; and this plan also was rejected by the engineer and returned to the contractors. The contractors afterwards submitted several other tentative plans for the construction of a cofferdam; but they were disapproved and rejected by the engineer. Subsequently the engineer suggested a different plan of his own for the cofferdam, the details of which were worked out by the contractors under the advice and approval of the engineer; and the cofferdam was finally constructed by the contractors according to the plan proposed, under the direction and approval of the government engineer in charge. The contractors objected to the plan as proposed by the engineer, but never made any formal protest as to its use. During its construction three breaks occurred, the first two of which occurred because of defects in the plan suggested and directed to be used by the engineer and these defects were such as the exercise of ordinary care and skill in the construction of cofferdams would have foreseen; the third break was owing to causes which could not have been foreseen by either the contractors or the government inspectors in charge. The repairing of these first two breaks cost the contractors the sum of $27,821.08. The several breaks in the cofferdam compelled the contractors to keep up the pumping plant and perform pumping in the excavation of the dry dock longer than they otherwise would have done. The first two breaks mentioned compelled the continuance of the pumping plan for 34 days longer than would have been necessary had these breaks not occurred, and the cost of said pumping was $37.20 per day, making $1,264.80 for 34 days. The specifications which were made a part of the contract provided:—

"The works included in the contract will be carried out by the contractors under the inspection and supervision of the civil engineer detailed for the purpose, who will inspect all the materials and workmanship and will have full authority to reject any which, in his opinion, are not in full accordance with the true spirit, intention and meaning of the contract, plans and specifications."

It is true that the contractors by these provisions of the contract agreed to construct the dry dock "under the inspection and supervision" of the government engineer, and "subject to his approval;" but we do not think that they thereby agreed to suffer any and all losses which might occur to them by reason of his mistakes in directing the manner in which the work should be done. We certainly do not think that they agreed to bear losses which might occur by reason of defects in a plan proposed and directed by him to be used, which the exercise of ordinary care and skill should have foreseen.

Numerous cases to the same effect might be cited, and we believe the rule in cases of this character to be that where a contractor constructs a work under a contract which provides that it shall be done under the direction and supervision of an engineer appointed by and under the employ of the owner and loss occurs to such contractor by reason of defects in the plans directed to be followed by such engineer, of a character which ordinary skill would have foreseen, the owner should pay for such loss. Following this rule the loss occasioned by the first two breaks in the cofferdam was allowed to the claimants.

(To be Continued)

Big Western Demand for Cement

The Canada Cement Company has re-opened its large cement manufacturing plant at Exshaw, Alberta, which employs about 3,500 men when working to capacity. It is probable that owing to the increasing demand for the company's product in the West, the Calgary plant will be started up later on. The mill at Exshaw is, however, the best equipped to handle the business, owing to its proximity to the cement rocks. The company has 13 plants in all, six in Ontario, 3 in Quebec, 3 in Alberta, and 1 in Manitoba. New building throughout the West is generally restricted, but the record crop last year brought in a demand from farmers for cement that is said to be the largest ever known.

Planning the Town of Iroquois Falls

An Industrial Centre Without Any of the Usual Objectionable Features—Utilitarian and Aesthetic at the Same Time

THE average industrial town is apparently designed without consideration of the broader principles of the art of town-planning, and, on this account, presents as a rule an unsightly, unsanitary appearance, with an utter absence of any sign of the aesthetic or the beautiful. Such a town is developed entirely through a spirit of commercialism and without regard to the welfare of its inhabitants, and results, without doubt, in their lowered mental and physical standard and their less efficient physical capacity.

Of late, proper industrial town planning has received more and more recognition and there has been a tendency on the part of many industrial concerns to lay out their town-sites with more consideration for the health, culture, refinement and pleasure of their people, by providing more room, easier accessibility, and greater attractiveness. The new town of Iroquois Falls, Ontario, planned by the Abitibi Power and Paper Co., in connection with its huge pulp and paper mills, is an illustration of this. In the case of this town, the officials of the company have striven to get away from the prevailing methods by providing such surroundings and environment as will contribute to the beauty of the town and tend to improve the contentment and happiness of the community.

The method of laying out this new town is described in an article in a recent issue of "Engineering and Contracting" by A. P. Melton, who acted in conjunction with the Abitibi Power and Paper Co. in working out the plan. The article in part follows:—

In planning the town of Iroquois Falls, Ont., Mr. F. H. Anson, president of the Abitibi Power & Paper Co., Limited, and other officials of the company, took up the matter with the writer with as much earnestness and with as much regard for detail and careful selection of site as they did in the construction of their great paper and pulp mills at this place. The mills and town are situated on the Abitibi River some 400 miles north of Toronto and about 150 miles south of James Bay. The mills are abundantly supplied with water power by the falls in the Abitibi River at this point.

An Ideal Situation

The town site is beautifully situated in a right angle bend of the river on a rolling plateau having an elevation of 125 to 150 feet above the river, this plateau being indented at various places by short and deep ravines, with an occasional ravine extending back for a mile or more from the river.

The gridiron system of laying out streets was followed in principal as being the most practical and economical method; however, the topography of the site was such that it was advisable to curve a number of the streets to get economical grades and at the same time utilize the maximum amount of the plateau, resulting in a very graceful layout without departing greatly from the gridiron principle. All business lots were made 25 by 125 feet in size and residence lots were in general 50 feet in width and from 110 feet to 150 feet in length. About 80 acres were laid out in the first plan and provisions were made for future extensions of about 160 acres.

The controlling features of the first plat, which is described and illustrated in this article, are the railroad and the edges of the plateau. A number of rectangular blocks were laid out adjacent to the railroad for business purposes, a small park forming a sort of civic centre and sufficient in size to contain all necessary public buildings was laid out adjacent to the railroad and business district, with the idea that the better class of business buildings will face this park, the bank, theatre and hotel being included in this class. A small park is also provided at the end of the railroad which, with the larger park, furnishes a screen between the residence and business portions of the town. The arrangement of these details will give a very pleasing "First Impression" to passengers alighting from the trains. Another advantage lies in the fact that children would not pass through the business district on their way to school. Locations are suggested for churches which add to the harmony of the layout.

Nine-Acre Playground

The school site shown contains about nine acres and it is intended that the school grounds shall be the public playgrounds and athletic park, for adults as well as children; also it is planned that the school gymnasium, and auditorium, be open to the public at all times when not being used for school work. Part of the school grounds are set aside for children's gardens, the idea being to give the children actual experience in growing such products as may be propagated in that far north climate and at the same time foster an interest in agriculture. The writer could say a great deal about the school plant if space would permit, as this institution takes care of about one-fourth of the population for several months in the year and is worthy of considerable comment. The school grounds as shown on the plat merge into a large park which includes two branches of a deep ravine that form the boundaries of the school grounds proper.

In laying out the streets a drive named Hillcrest Road, was laid out around the edge of the plateau, following as closely as possible a certain elevation, and laying out interior streets to approximate the usual gridiron system, most of them being curved to conform to the general direction of the contour lines, and wherever possible terminating all interior streets in the heads of the various ravines at the edge of the plateau, thereby providing a useful and economical dumping place for dirt excavated out of the streets, and also enabling more ground to be utilized for building purposes. Grades were established so that the sidewalk would be slightly lower than the general property grade to provide proper slope from the house to the sidewalk, the average cut being from 1 to 2 ft. in the paved portion of the street, most of this excavated material being used in filling up the heads of ravines. The same irregularity in grades is practiced as in street lines, the grade lines following as closely as possible the contour of the ground and all changes in grade being connected by means of vertical curves consisting of a change of 1 per cent. in grade for each 20 feet of horizontal distance. It was attempted to keep all grades under 7 per cent., but one of 10 per cent. was established for a short distance.

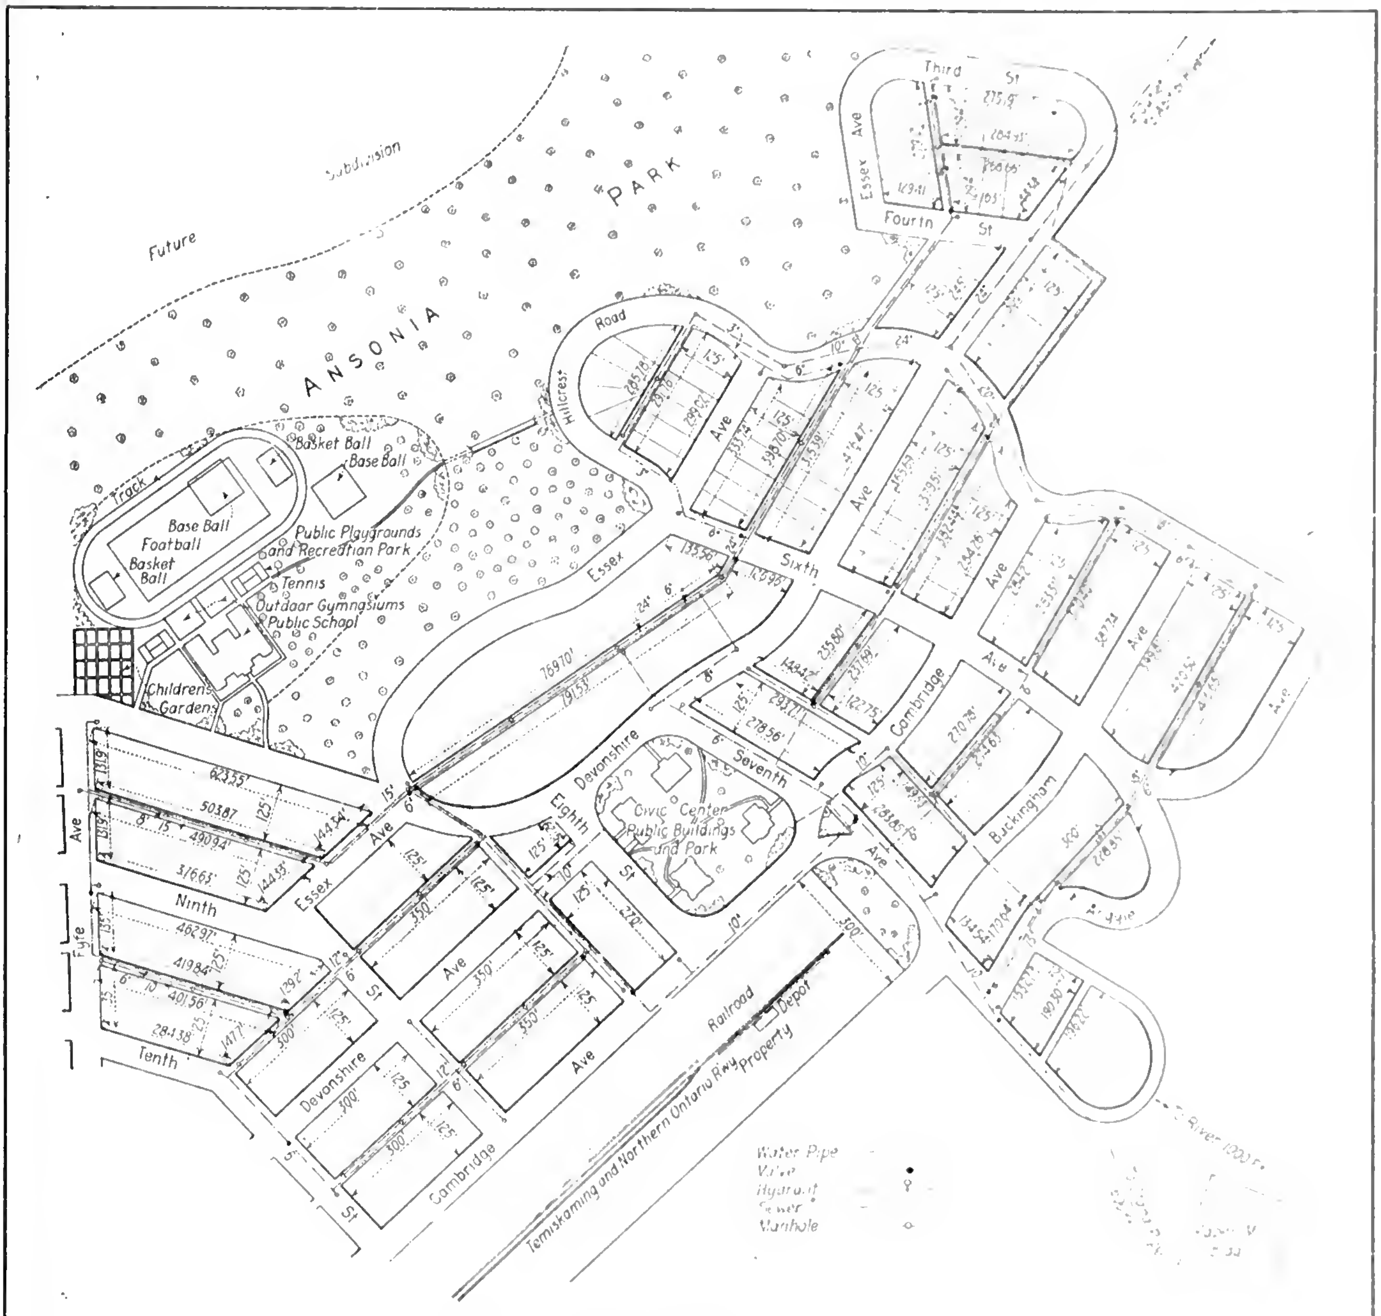
Nothing out of the ordinary was attempted in the way of improvements, all streets being of macadam with combined curb and gutters and 5 ft. cement walks, residence streets having a 22-ft. roadway between curbs, and business streets 36 and 40 ft. Macadam, stone and gravel are obtainable within a short distance, while any other material would have to be shipped 500 miles or more.

Sewers are all collected into one 24-in. outlet which discharges into the river below the town and all have more than ample fall. All sewers are to be constructed of vitrified tile.

The water supply is taken from the Abitibi River above the town and is treated by means of a Norwood Engineering Co. coagulating and pressure filter installation.

All Water Mains Seven Feet Deep

On account of the severe climate, it is necessary to have at least 7 feet cover over all water mains. The water in the river has the characteristic color due to vegetable matter common to all streams in this locality, but being in a virgin forest is polluted in no other manner and is perfectly pure after the filtering process.



Ideal town plan—The industrial site of Iroquois Falls, Ont.

The company furnishes electricity from its hydro electric plant for domestic and street lighting. Sewers, water pipes, and light poles are placed in alleys wherever practicable.

The soil is clay and is heavily timbered with spruce, balsam, tamarack, poplar, and some birch.

The population of the town will probably never exceed 2,500, as not more than 500 operatives will be employed in the mill; however, a much larger force will be employed in the woods, but will make their headquarters elsewhere.

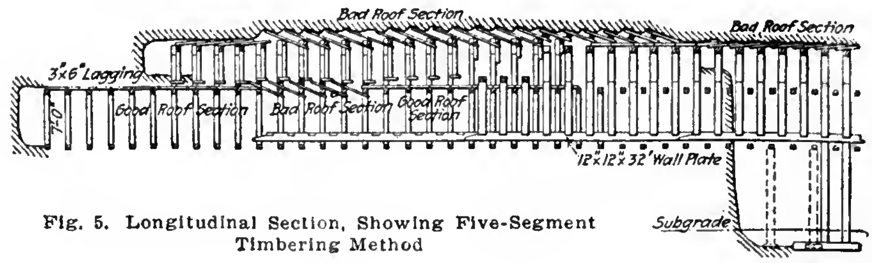

Fig. 5. Longitudinal Section, Showing Five-Segment Timbering Method

Rogers Pass Soft-Ground Work

By J. G. Sullivan*

TUNNELING by such a method as to make the larger part of the excavation yardage accessible for steam-shovel mucking is the feature of the Rogers Pass tunnel work on the Canadian Pacific. This method might not seem well adapted to soft-ground work, but it has been applied with full success in the two portal sections as well as in several soft-rock sections farther in.

At the east end there was 1,300 feet of tunnel through more or less cemented mountain debris. The method followed here was first to drive two wall-plate dirfts (see Fig. 1 herewith), then stope out between these two drifts at various points (Fig. 2) and place five-segment arch timbering (Fig. 3). The core of the cross-section and everything below the wall plate was excavated by steam shovel (Fig. 4), the shovel removing over 66 per cent. of the total excavation in this section.

Practically the same method was followed in several soft spots encountered in solid rock. The tunnel was stoped out to the level of the wall plate and the arch timbers placed.

Seven-Segment Method in Loose Wet Ground at West End

At the west end there was about 400 feet of very heavy ground, consisting of much looser material than at the east end. It contained large boulders and carried considerable water. The method employed here differed from that used at the east end in some important particulars. A seven-segment arch was used, and it was carried directly on posts instead of on a wall plate. To set this timbering five drifts were used. There were two superimposed drifts on either side, clearing a way for the posts, and there was also a crown drift. As soon as the posts were set, the ground between the upper post drift and the crown drift was stoped out and the arch segments set.

This method, of course, was very expensive in the use of timber, but it permitted the steam shovel to excavate the entire core of the tunnel, at this point about 51 per cent. of the total excavation. Except for the desirability of getting the steam shovel into rock as quickly as possible, very much lighter timbering and bracing would have been used. The essential purpose of the whole method was to allow the steam shovel to go through and reach rock as quickly as possible.

One peculiarity about this section, which caused some concern, was the problem of how to support

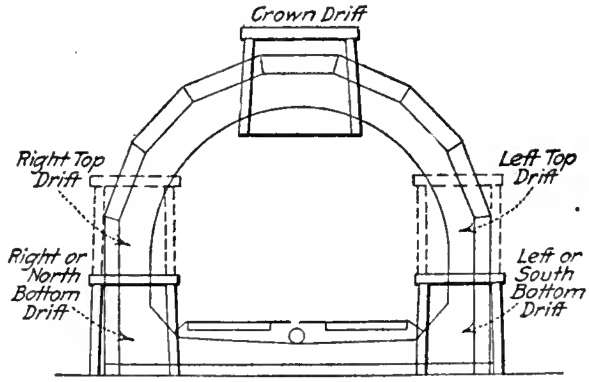

Fig. 6

the roof load until a concrete base could be put in. The top load was so heavy that even 12 x 16-in. timbers set solid would not carry the burden without crushing. These timbers were doubled, two sets of posts as well as two sets of arch timbers being used.

The posts rested on mud sills no wider than the post, and, strange to say, no settlement took place, in

*Chief Engineer, Canadian Pacific Railway, in Engineering News.

spite of the fact that the ground was very soft when disturbed. The ground when worked up by the steam shovel would get so soft that the shovel would have buried itself if not carried on a solid floor of timbers. The explanation is, of course, that when the water was drained off the ground became very hard, and that the roof timbers acted as a perfect arch, carrying the load to the surrounding ground by arch action instead of transmitting it to the posts.

The original intention was to put in a solid floor of concrete, as shown in Fig. 6, but finally only a strut 18 in. wide every 30 feet, was used.

Increasing Building Activity

Lambton Mills Public School

The new public school at Lambton Mills will be a handsome addition to the buildings of that community. The school will have four standard class rooms, teachers' room, principal's room, and play rooms in the basement.

The building will be constructed with Milton rug brick with stone trimmings. The particular feature of the building outside of the exterior artistic effect is the placing of the main corridor on one side of the building rather than in the centre. There will be two separate staircases, one at each end of this corridor. In the interior equipment very little trim will be used, so as to eliminate any lodging places for dust and dirt. The floors and such trim as will be used will be hardwood. The class rooms are all naturally lighted from the east and are also provided with electric light. The Pease heating system of forced ventilation will be installed, also a private sewage system with septic tank. The boiler room will be thoroughly fireproof, and the building will be provided with four exits so that it can be rapidly emptied in case of emergency. The school was designed by Ellis & Ellis, architects, Toronto; the general contract has been awarded to R. Mudghall.

Children's Home, Belleville, Ont.

The illustration herewith shows the architect's sketch of the new Children's Shelter being erected by the Children's Aid Society on Dundas Street East, Belleville. The architects are Ellis & Ellis, Manning Chambers, Toronto. The building is a three-storey and basement brick structure, designed in the Georgian style of architecture. In plan it measures about

Belleville Children's Shelter—Ellis & Ellis, Architects.

54 feet by 48 feet. The exterior of the building is made as plain and free from excess ornamentation as possible and yet of such a character as to make it home-like in appearance, so as to avoid any indication of an institutional type of building. The interior is planned with all the essential requirements of a children's home, with recreation rooms, dormatories, infirmaries, and three large sun rooms.

Messrs. Allen and Harvey, Belleville, are the general contractors, and the estimated cost is about $17,000.

Roof Materials and Roof Coverings

A Protection and Safeguard to the Building Often Given Only Secondary Consideration—Choice Dependent on Many Factors

THE roof of a structure is as important as any other single part of its make-up. It serves to protect and safeguard the building and its contents from the action of the elements, and so important is this purpose that careful consideration of its design and construction is essential. The roof covering especially, or that part of it which is exposed to the exterior, requires particular care in its choice, for it is upon this that the wind, heat and light have their effect. The object of this article is to endeavor to set forth some of the conditions that most affect the selection of a roofing material and to describe the properties of a few coverings most commonly employed.

The roofing materials in ordinary use have in each case more or less limited applications; that is to say, no one material can serve in every possible type of design. There are a large number of considerations that must be taken into account when a suitable material is desired. Those factors that bear most upon the choice of a roof covering are enumerated and enlarged upon below.

Factors Governing Choice

First, type of building: The type of a building and its purpose obviously influence to a very great extent the design which a roof must have and in this way, the material of which the roof covering must consist. Attention must be paid to the purpose for which a building is intended and the permanence of its construction.

Second, the pitch of a roof: It is extremely important that a roof material be adapted to the pitch of the roof. There is a certain limitation in this regard to the use of all roof coverings. Thus, roofs of slate, tile, unsoldered tin, etc., are used only on sloped roofs, whereas gravel and tar are applicable to flat roofs exclusively. If the pitch and the material are not properly related, leaky roofs are sure to result. The following table gives the desirable slopes that may be safely used with the roofs mentioned:—

Material	Rise of Roof per ft.
Wooden shingles	6 in.
Slates	6 in.
Tiles	4 in. to 7 in.
Corrugated iron	4 in.
Tin plate	1 in.
Concrete	Flat
Tar and gravel	½ in.
Asphalt	½ in.
Ready roofing	1 in.
Asbestos shingles	3 in.

Third, strength and rigidity: All external roof loads, such as due to wind and snow, act primarily on the roof covering, from which they are transmitted to the rafters, trusses and walls. The covering must be of such strength as to carry these loads with a reasonable factor of safety and of such rigidity that excessive deflections will not be caused. The load acting on the roof varies within a wide range, but a roofing material must be chosen for the maximum estimated load. The wind load varies according to the pitch and exposure, and snow depends on the slope and on the climate. Even with steep roofs, where the snow load is negligible, a sleet load, which will cling to a roof of any steepness, must be calculated.

Fourth, durability: A roof must show an ability to wear and to resist abrasion from weather. It is essential that the roof should last as long as possible without repairs.

Fifth, resistance to weather: This is the most essential requirement of a good roof covering. It must withstand the effects of rain and snow, heat, cold and wind. Its construction must be such that no water will remain in the joints, and provision must be made for expansion and contraction.

Sixth, fireproof qualities: The fireproof requirements of a building vary widely with its purpose and location, but it is important that a roof should be fire resistant, to prevent spread of fire from one building to another, as well as for a building's own protection. Many fires are caused by the roof of a building acting as a spreading agent. Many roof materials are entirely unsuited for fireproof or even fire resisting construction, and the question that governs the selection of a suitable covering is the degree of incombustibility desired. The qualities that relate to the fireproofness of a roof are: (a) inflammability; (b) fire retarding properties, that is, its ability to resist spread of fire on the surface, or to afford protection to the roof structure against exposure to high temperature; (c) blanket effect upon fires within the building; (d) danger from flying brands. In considering the fireproof qualities of a roof, its liability to act as a target for lightning must also be conisdered. In ordinary buildings in which there are stair wells or elevator wells, the roof is likely to be severely tested by heat in case of fire and this is the part that is most often neglected.

Seventh, expense: The item of expense enters very considerably into the selection of a roof. The question that often must be carefully considered is the balancing of low first cost with heavy maintenance charges and short life against higher cost with longer service.

Eighth, architectural considerations: This also enters very widely into the choice of a roof, especially in residences or monumental structures where beauty and appearance have a great deal of weight.

Ninth, temperature within a building: Radiation through roofs of certain kinds is a serious problem. A building can often be too hot in summer and too cold in winter through excessive roof conduction. This necessitates insulation of some type. Of a similar nature is insulation against condensation which may cause damage to machines and products as well as annoyance to operators. Condensation also has a material effect upon the deterioration of metal roofs.

Tenth: Location and availability of labor and material, with the consequent effect on cost must be taken into account.

There is a wide range of materials suitable for roof covering. Each has its special field of application and has certain advantages and disadvantages. The most common of these are discussed in the following paragraphs:—

Wood Shingles

The best shingles are those made from cypress, cedar, red wood, white and yellow pine, and spruce, in the order named. Shingles have the advantage of low cost and easy application, but their combustible nature prevents their use in buildings which must be of a fireproof nature. The scarcity of material is increasing the cost of good quality shingles and encouraging substitutes. To increase their durability, they are sometimes creosoted or painted. Paint is said, however, to increase decay by closing the pores and preventing rapid drying after exposure to rain or snow. Wood is also employed in the form of sheathing as a base for other roofing materials.

Slate

A good slate should be hard and tough, should have a metallic ring when struck, and should be easily holed without danger of fracture. Slates are durable and reasonably fireproof, and the range of colors in which they occur can be utilized to produce good architectural effects. They have a tendency to crack and conduct heat and cold rather easily. They are laid on wood or beds of cinder concrete, which holds nails as well as wood.

Clay Tiles

Clay or terra cotta roof tiles are used extensively for roof building. They are fireproof, durable, require no painting and are poor heat conductors. If well made, they are moisture proof, more especially if semi-vitrified or glazed. Both flat and interlocking types are used, the latter being considered to make the most satisfactory roof. Non-waterproof tiles are often used as a base for the addition of waterproofing material. The hollow, so-called book tile, set on tees, is frequently used. The high cost of tile is its chief drawback. An additional expense is entailed on account of the increase in strength which must be made in the supporting frame to carry the heavy dead weight. The variations in color of clay tile lend themselves to the production of architectural effects.

Glass tiles are also made of the same shape and size as clay and are used where skylight space is desirable without breaking the continuity of the roof surface.

Metallic Roofs

Iron or steel possesses may suitable properties for a roof material. Its quality often depends to a large extent on the purity of the metal, and it must be protected to prevent corrosion. The plain undipped sheets require painting for their preservation. Corrugated sheets are very extensively employed for the roofing and siding of mills, sheds, grain elevators, and warehouses. The best grades of corrugated sheets are now made of double-refined, box-annealed, iron or steel. The corrugations are usually made lengthwise of the sheet and are intended to give longitudinal strength and incidently improved appearance. Corrugated sheets can be used without underlying support except the purlins. Their life is increased by galvanizing or coating with zinc, which, on account of its low corrodibility, prevents rapid deterioration. This process increases the weight approximately 2½ oz. per square foot and the cost about 30 per cent. The zinc coating should be applied after corrugating so that the process of stamping will not injure it.

Tin and terne plate are iron or steel sheets dipped in molten tin, or terne, which is a mixture of tin and lead. The heavier the coating, the more valuable the plate, as it is more resistant to corrosion. A tin roof properly put on and properly painted will last from 40 to 50 years, or longer. These roofs require painting, however, every few years, and it has been proven that certain paints, notably those containing graphite and tar, are injurious.

Iron or steel roofs are light, yet sufficiently strong in most cases, are fire resistant, are lightning proof and easily applied. Their lack of durability is a disadvantage, and painting is required at frequent intervals. Heat conduction and condensation are drawbacks, necessitating an insulating layer underneath.

Copper is one of the most durable and lightest of roofing materials, but its expense prohibits its extensive use. It requires efficient insulation to prevent heat radiation.

Lead and zinc roofs have not found favor on this continent.

Concrete

Concrete slabs or tiles of interlocking types, made in the factory and reinforced with metal fabric or mesh, may be laid without sheathing on steel purlins. This type of construction is often only semi-fireproof since the slabs are usually of insufficient thickness to prevent failure of the reinforcing. To make the roof waterproof, an ordinary roofing material is usually laid on top.

Monolithic construction—In this method the covering is made by spreading concrete either on reinforcing supported by forms or on self-supporting expanded metal requiring no forms. The construction can be so made as to keep the thickness down and lessen the dead weight. Concrete roofs are durable and fireproof if the reinforcing is properly protected, and have a considerable strength. Their weight is sometimes objectionable. Since the slabs are thin, heat radiation takes place, and insulation must be used to avoid this and to overcome condensation.

Concrete is also used on roofs as a base for tile, slate, or tar and gravel.

Built-up Roofs

These, as the name indicates, are made from various materials directly on the roof. They usually consist of several layers of saturated felt laid on wood or concrete and coated with tar or asphalt and protected with slag, gravel, or cinders, imbedded in the coating. Both tar and asphalt are subject to adulteration, more especially the latter. Moreover, the use of certain oils for fluxing may cause internal change in asphalt, and in consequence, tar is more dependable besides being cheaper and is more extensively used.

The felts used in built roofs are merely media for holding the pitch in place.

A coating of gravel, slag, or stone is used to keep the pitch in place and to protect it from the elements and to give the covering some fireproof qualities. Tiles are occasionally used.

As the materials melt in the heat of the sun, coverings of this type can be used only on flat roofs.

Ready Roofing

There are innumerable, so called, prepared or ready roofings, which are made by cementing together two or more layers of saturated felt and then coating with some material which may be of either fine or coarse nature. These roofings are put up in rolls or sheets, are easily applied, and require no previous experience in setting up. They make excellent coverings in many cases, especially in roofs where the rise is one inch or more per foot, in which case ordinary gravel would roll off.

Asbestos

Asbestos is sometimes used on roofs in the form of either sheathing or shingles. Asbestos sheathing is corrugated asbestos building-lumber reinforced with sheet steel or woven wire netting. It is applied the same as corrugated iron.

Asbestos roofing shingles are made of asbestos and cement. The advantages claimed are their fireproof qualities, toughness, elasticity, lightness in weight and ease of manipulation, cutting and sawing. Various colors are now on the market. The cost is higher but maintenance is low.

The above description applies to the most commonly used roofings. There are others that are less extensively employed and have more or less uncertain advantages, but those mentioned are the standards used in all modern building construction.

Concrete Foundation Construction

THE modern type of building has introduced new problems in foundation construction. There has, in recent years, been a remarkable development in concrete pier work, as these have turned out to be often the only satisfactory supports for large structures. Many new and ingenious methods are constantly being displayed for their construction, and unquestionably, the work attempted at the present time would have been impossible only a few years ago with the facilities then at hand. From time to time the Contract Record has mentioned instances of concrete pier work, and believing that new methods and ideas are always of interest to contractors and engineers, we give in this article a sketch of the methods used in laying the foundations of the Buffalo General Electric Company's new 100,000 kw. steam generating plant on the Niagara River. This case illustrates particularly well the use of steel cofferdams, composed of sheet steel piling of the well known Lackawanna make. Sheet steel piling of this nature has many practical advantages, which in this instance undoubtedly contributed to the ease with which the piers were sunk. The entire driving force can be concentrated on a single unit of small width, resulting in the penetration of obstacles that would have proved difficult or insurmountable for rigid caissons as usually employed. A great deal of ingenuity was displayed in the methods adopted for handling the piling, excavating and concreting, all of which contributed to the rapidity with which the work was carried on.

The site of the power house is on the bank of the Niagara river near Buffalo. Tests showed a level solid rock 40 feet below the surface with the intervening soil consisting of 9 ft. of soft mud, 28 ft. of water-laden quicksand and 3 ft. of half and half clay and boulders. The requirements of the building and the nature of the soil necessitated foundations to bed rock and so fixed that any movement of the quicksand would not cause distortion.

The plan determined upon called for about 160 concrete piers with diameters varying from three and a half to nine feet. The caisson shells were composed of Lackawanna, 12¾ x ⅜, straight section, interlocking, sheet steel piles, 33 ft. long. The piles for the smaller caissons were curved at the mill to suit the circle required, but the angle allowed by the interlocking joint did away with curving for the larger caissons. These shells when driven remain as permanent sheeting around the piers. About 1,300 tons of piling was required.

Interlocking piles require assembling before being driven, and it was therefore necessary to be able to raise one pile high enough above another so that the interlocking joints would engage. This meant that with the 33 ft. piles, provision must be made for the upper end of the upper pile to be 66 ft. above ground. To allow this, two cableways were constructed about 70 feet high, and when the piles were taken from the trolleys they were picked up one by one by the cableway, and assembled together in the caissons.

To insure a perfectly vertical and circular shell, driven at exactly the correct location, as well as to provide a foundation for the steam hammer, a wooden pile was driven in the centre of each of the positions. In this pile a 12 in. deep, 3 in. diameter hole was bored, a wrought iron hoop driven over the top of the pile to keep it from splitting and a steel pin, 20 in. long was inserted. This pin held in place a circular, horizontal template of the same diameter as the interior of the caisson. For the support of the steam hammer a heavy wooden mast, 42 ft. long, was then set so as to rest on the 3 in. steel pin, and thus extended up 9 or 10 feet above the top of the caisson. This mast was guyed by wire ropes. A second circular template was secured to this mast 17 ft. above the first one. This mast, to which the driving hammer was now attached, was left free to revolve. The steam hammer was supported by a ring that allowed it to slide upon the mast and revolve with it. The feed lines passed through a set of double blocks on the top of the mast to a stationary engine.

In setting the caisson the first steel pile was raised and placed in a vertical position against the templates. A second pile was then raised to the top of the first, the joints interlocked and the pile lowered. This process was continued until the shell was complete. Two piles were always driven at the same time and to a depth of about 3 ft. The hammer was then raised and revolved to the next two piles, which were driven in the same distance. The operation was continued in this way until rock was reached. Twelve masts and five hammers were used at once, the extra number of masts allowing assembling work to be carried on ahead of driving work.

For excavating, a multi-stage, centrifugal pump of 1,500 gallons per minute capacity was installed. Six-inch distributing pipes carried the water close to the caissons. A 6-in. sand jet pump and two water jets were placed vertically on the earth material inside the caisson, the upper end of the supply tube being closed by a valve. The water was turned onto the jet, and as it could escape only through the bottom, the tube settled rapidly by its own weight to a point close to the rock. The valve on the pump was then opened and immediately a stream of sand and water was discharged, having been loosened by the high pressure jets. This method excavated each caisson in about two hours. The boulders and clay just above the rock were broken up and removed and the bottom was carefully washed with jets to insure perfect cleanliness.

The reinforcing steel was then inserted, having ben previously assembled, and the concrete was poured from a travelling mixer (which ran on a railway track laid between the lines of caissons), through an ordinary water-tight tremie pipe, the mouth of which was kept always below the surface of the concrete. After a day or so the water was pumped out and the laitance removed.

The city of Hamilton are distributing a very complete report submitted to the Board of Control and the aldermen of the city by the city engineer, giving an account of the work done in the several departments under his charge. The present population of the city is given as 100,461; acreage, 7,143, and the assessment value, $79,700,752.

Science of Wood Preservation

WOOD is an organic body and as such is subject to decay. As a structural material its advantages in many respects have never been surpassed, but this inherent tendency to decay produces a drawback that is not possessed by metals. This has led in recent years to the industry of wood preservation. Another factor has contributed largely to this—the fact that the forests have been so stripped of those timbers which best resist decay and insects, making them unduly expensive. This has roused the consumer to turn his attention to the available timbers, since the results of many experiments have shown that by proper treatment these can be made to supply his needs practically as well and at a lower cost.

The yellow pines have been largely treated in this way. Lately, gum and beech timbers have been treated extensively in the United States for cross-ties. In Europe, the beech has been one of the cross-tie woods for many years, its value, when properly treated, having been long recognized. European railroads often secure as much as 25 years' service from properly treated beech cross-ties, whereas if untreated they would scarcely last long enough to warrant their use at all. Until recently the oaks and southern pines furnished the majority of ties bought by railroad companies on this continent, but now the advantage of timber treatment is being fully recognized and these more expensive and less plentiful timbers are fast being replaced by the other woods.

Wood is an organic body with an outer layer composed of sap-wood and water, containing cells, in which there is a large amount of organic substances, and with an inner structure called heart-wood usually distinguished from the sap-wood by its dark red color. Heart-wood is filled with gums and resins and contains less water than the sap-wood and therefore is more durable.

Excluding Moisture

Bacteria, insects, or fungi, get into the organic cells and by feeding on the cellulose, destroy them. By excluding heat, air, or moisture, decay can be prevented or retarded, but this method is usually impracticable, so that the cell-walls or fibres are impregnated with such a material as will prevent the destructive agents from getting in. In some cases the preservative is merely a mechanical hindrance to insects and worms, but in the case of heavy treatment it excludes air and moisture, preventing vegetable or fungi growth from developing.

Moder timber preserving is accomplished largely by the use of materials such as are found in coal tar and some metallic salts. The creosoting process is very common, but in many buildings the use of creosoted timber is not permissible, owing to the odor which is emitted and to the effect of creosote on the appearance of the wood. Some salts, such as mercuric chloride, copper sulphate, and certain arsenic salts, are fairly good preservatives, but owing to their poisonous nature are objectionable, especially in dwellings. Sulphuric and hydro-chloric acids, while destroying the fungi, are liable to injure the wood. Coal oil has been tried and is quite effective, but it increases the inflammability of the wood and causes it to emit a disagreeable odor for a considerable time. A sulphate of salicylic acid is probably as effective as creosote and leaves the timber odorless, but its expense is its objectionable feature.

The first stage in any timber preservation process consists of seasoning the wood, either by piling in the open air or by steaming in closed retorts to expel the moisture and sap. Care should be taken in piling the timber for seasoning, that a free circulation of air is allowed around the timbers. In some cases the lack of this has caused deterioration through decay before treatment took place. The bark should be removed, for often it prevents the evaporation of sap and moisture. The steaming process facilitates the removal of the contents of the wood cells, and in addition, by raising the temperature, sterilizes the wood and prevents absolute deterioration by rot as long as the outside cells are filled with the preservative. Great care is required in steaming the timber so as not to injure the wood. The cells may be damaged by the expansion of steam formed from the sap and water in the cell or they may be charred by too much heat.

Proper Seasoning

The time of year when timber is cut determines to a large extent the method of treatment. The time of cutting bears an important relation to the life of the timber and with some railroads the months are specified in which cutting is to take place. If cut in winter months when the sap is out of the tree, and placed where it can get the spring rains, the pores of the wood, being open, get water-soaked and rot quickly. On the other hand, if cut when the sap is up and placed where the hot sun will shine upon it, it will also rot very quickly—more quickly than the winter-cut, water-soaked timber. If it is piled in open cribs, however, and seasoned, it will last very much longer. Winter cuts will take some water even after six months' seasoning. The timber cut in the spring and properly stacked will, after the same seasoning, shrink considerably in cross section. The pores of the wood close up and will not absorb water even under unfavorable circumstances. The sap, particularly in oak, is a tannic acid, and when drying up closes the pores and acts as a preservative, thus rendering the wood much more durable than if it were winter cut. Also, if southern or Norway pine is cut when full of sap, the sap will commence to crystallize and turn to resin in about a month, increasing the life of the timber three or four times that of winter-cut wood.

Preservatives

The methods of treating timber with preservatives are: (1) the pressure process; (2) the non-pressure process. Each of these groups may be subdivided into two divisions, (a) the full cell process in which the cells are left filled with the preservative, (b) the empty cell process in which the preservative, after being absorbed by the timber, is withdrawn by means of a vacuum created in the retort, leaving only the cell walls coated with the preservative.

The pressure process gives a heavier and more uniform penetration and impregnation than the non-pressure process and is on this account more desirable for large structural timbers. The non pressure process is much cheaper and so is largely used for treatment of cross-ties and other timbers where a heavy treatment is not necessary and where the mechanical life of the timber is the determining factor after treatment. The full cell process leaves the timber more water-proof and air proof than the empty cell process, but the latter is largely used on account of the saving of preservative, if there is little danger of water soaking in.

Probably no branch of construction work has benefited more by the study and practice of timber treating than has the building of under-water structures. Deterioration of submarine structures may be divided into two classes, deterioration at the surface and deterioration beneath the surface. Timbers of this nature are attacked not only by rot but also by ship worms which bore into the wood and destroy the cell walls.

It is essential for the successful treatment of piling that a preservative which is insoluble in water be used and where the piles are to be placed in salt water the preservative must possess strong antiseptic qualities and resist the action of ship worms. Since a deep and thorough penetration is essential the woods of relatively high absorbing qualities should be chosen.

Some piles forming part of a dyke in Connecticut were treated by the full cell process of creosoting. They were driven about 1886 and since then have been subjected to very severe conditions. They were driven in salt water and are alternately covered at high tide and exposed at low tide. After 20 years' use many of the piles were in as good condition as when put in, and in the few cases where deterioration had set in, it was due to rot which apparently began in the top and worked down through the middle, leaving a shell. The ship worms, it seemed, had done no damage except where the timber had first begun to rot. If the top had been thoroughly protected, it is likely that no appreciable decay would have taken place.

Poles Used by Public Service Corporations

Telephone, telepraph and electric power companies consume millions of poles annually and the number is rapidly increasing. The greater number of them are cedar, with some chestnut. Since the region of supply is limited and transportation is expensive, however, cheaper woods are now being treated. According to bulletin issued by the Forestry branch of the Department of the Interior at Ottawa, an annual saving of $6.40 per mile of line may be realized by the proper creosoting treatment of cedar poles.

The preservative treatment of poles has many features to recommend it in Canada. The supply of cedar is comparatively small, and since its growth is very slow, requiring from 175 to 200 years to produce a 30-ft. pole, it is not equal to the demand. Cheaper woods, such as spruce and pine, when properly treated by preservative, are as satisfactory as cedar and they are more plentiful. This will save money and lessen the drain on the forest.

Fire-killed timbers, which occur in quite large quantities on the eastern slope of the Rockies, in a sound, strong and well-seasoned condition, should make even better poles than cedar when properly treated. They have been treated in the United States with very satisfactory results. They stand in good pole sizes and are more convenient for the extensive prairie market than poles now brought from the east.

A few years ago a power company in California set a 30 mile line with poles of western yellow pine. The poles were cut at an elevation of about 4,000 ft., and were thoroughly seasoned before treatment. About 50 per cent. of the poles were given an open tank, creosote treatment, some of the others were given a similar treatment with zinc chloride and some with crude oil. A few were given a brush treatment with carbolineum and crude oil. In order to get the comparative life of the wood, treated and untreated, stubs of untreated timber were set along the line about one mile apart.

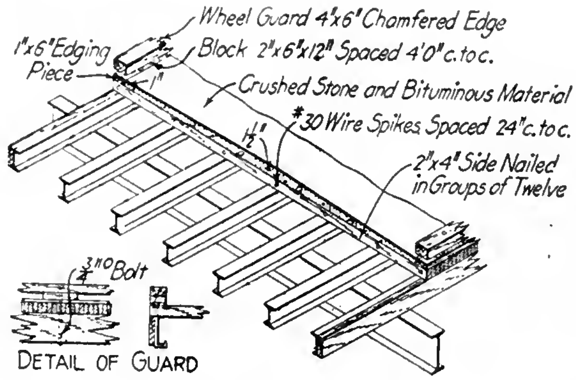
After 27 months the untreated stubs were completely rotted, nearly one-third of the brush treated poles showed decay, those treated with zinc chloride were in nearly the same state, and 45 per cent. of the poles treated with crude oil showed signs of decay, while all those treated with creosote were perfectly sound.

The question of cost governs the application of the process to a large extent. Assuming that timbers put to a certain use will last ten years without treatment, and 20 years with treatment, then, disregarding interest charges, it is evident that in order to effect a saving, the cost of treatment must at least be less than the additional cost of new timbers ten years hence. In treating on a large scale, the additional cost in most cases will not exceed the present purchase price of timbers, and so the saving secured will be at least the cost of resetting the timbers plus the advance in the price of the timber. The replacement of timber often causes loss by entailing the shutting down of the plant, as in replacing a mine shaft.

Each process of treatment has certain defined applications and the particular method to be used depends on such considerations as the cost, degree of impregnation desired, the nature of the wood to be treated and the use to which it is to be put. To secure the best results, the mechanical treatment of the wood, that is, its subjection to stress must be so arranged as not to be out of place with its chemical life. The strain should be distributed throughout the whole timber as far as possible, so that there will be no premature failure in small portions due to their bearing too great a share of the work.

A New Idea in Bridge Floor Construction

Plank flooring for bridge construction where heavy traffic is encountered is expensive and difficult of maintenance. It is necessary in some cases to re-plank floors every few months, or at least once a year. In the towns in the State of New York there are many light truss bridges which were originally designed for plank floors. The cost of upkeep on these floors is very great and the danger caused by broken planks



Placing Solid Flooring and Surface Finish.

must always be considered. The live load which they are called upon to withstand at the present time is larger than ever before, due to the great number of motor trucks and road rollers now so common. The metal of the bridge has not always had proper attention, and the result is that in the majority of cases there is not sufficient metal to carry the present live loads and at the same time permit of the use of a concrete floor. An improved method of construction adopted by the commission of highways of the State, is described in the Engineering Record as follows:—

As a money saver, and also as a means of causing less inconvenience to the travelling public, the Bureau of Town Highways of the State Commission of Highways is recommending the use of 2 x 4 inch joists in place of ordinary plank. The drawing herewith shows the method of placing this solid flooring, and the surface finish. Creosoted joists, of course, furnish the most ideal floors, and these are used in some cases, a treatment similar to that given wood blocks being applied.

Timber Treated While Laying

In order to lower the cost and at the same time keep the money for labor and supplies at home, many of the towns are providing their own treatment while actually laying the floor. Ordinary 2 x 4 inch stock is used, and is dipped in hot tar or asphalt and then allowed to drain before placing. If the wood contains much moisture or sap no treatment is given the bottom, this surface being left free for the escape of moisture or sap, which is believed to prevent rot. The joists are spiked together in blocks of ten or twelve and those blocks are toe-nailed at their ends. This is to facilitate the removal of any joint when necessary, as only a small number of the adjoining joists have to be disturbed.

Over the top surface is placed a heavy coat of hot tar or asphalt, and on this as a blotter is spread some crusher screenings or sand and gravel; some provide a thicker coat, using crushed stone, but this adds largely to the dead load. This makes a wearing surface and at the same time waterproofs the floor. This surface should be carefully preserved, but its cost of upkeep is very small.

Some of these floors have been in use for five seasons. One in particular, which is on the state highway leading down the Mohawk River just outside of the city of Utica, is heavily travelled, and yet to-day, after five seasons, is in first-class condition. On this same bridge, before providing this type of floor, the oak plank had to be entirely renewed every year, in addition to some extra attention from time to time. All of the results obtained to date favor this type of floor for light truss designs.

Satisfactory Progress on Aqueduct for Water Supply of Greater Winnipeg Water District

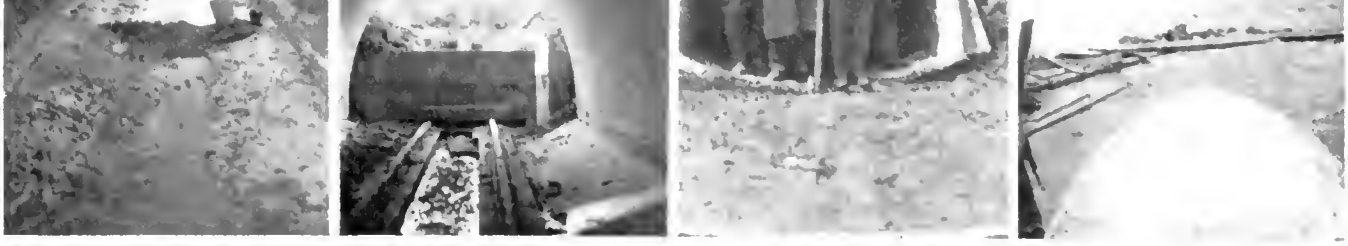
A NUMBER of illustrations reproduced herewith show various phases of the construction work in connection with the Greater Winnipeg Water District supply. It will be recalled that the city of Winnipeg voted $13,500,000 dollars to bring a supply of pure drinking water from Indian Bay in Shoal Lake, approximately 100 miles distant from the city. A concrete viaduct, of the shape shown in one of the illustrations and approximately 8 feet in diameter, is being constructed through the entire length. One of the photographs shows the method adopted at river crossings. At eight such points tunnels have been excavated under the river and the viaduct, of inverted syphon shape and standard dimensions, installed.

The undertaking included the construction of a railway paralleling the line of the aqueduct, which, with equipment, has cost the city of Winnipeg about $1,500,000. The railway construction and the rolling stock is standard and will be a valuable asset to the city after this work is completed.

An interesting feature of the work has been the discovery of a red granite quarry 71 miles out from the city, which is claimed to contain almost unlimited quantities of the finest texture granite. It has been said that this is the finest granite on the continent. A company has already been formed to work the quarry.

Another beneficial result of the work, which was probably not foreseen at the time, is that the drainage facilities provided by this construction have greatly increased the value of the land in the immediate vicinity of the aqueduct. It is said that some of the most productive land in the province lies along this line and settlers are already taking advantage of the improved conditions.

Some idea of the scope of the work may be gathered from the last monthly progress report of Chief Engineer Chace to Chairman Reynolds, of the Greater Winnipeg Water District Commission. It indicates that at five points construction is being carried forward. Three contracts are held by the Winnipeg Aqueduct Construction Co., one by the Tremblay-



Various construction views of aqueduct—Greater Winnipeg water supply.

Inside forms and carrier for outside forms.

Dyke which diverts Falcon River.

McDiarmid Co., and one by Thomas Kelly & Sons. The report, which is reproduced below, compares the activities of the early summer of the present year with that of the year 1915.

Progress for the month of May, 1916, was as follows:—

Contract 30 Aqueduct Construction	Date of Beginning Concrete, 1915
Camp 1—Commenced to pour concrete May 27th.	
Camp 2—Commenced to pour concrete May 17th.	June 14th
Camp 3—Commenced to pour concrete May 20th.	June 12th
Contract 31 Aqueduct Construction	
Camp 1—Has not yet commenced to pour concrete	June 2nd
Camp 2—Commenced to pour concrete May 31st.	June 21st
Camp 3—Commenced to pour concrete May 19th.	June 28th
Contract 32 Aqueduct Contsruction	
Camp 1—Commenced to pour concrete May 15th.	July 7th
Camp 2—Commenced to pour concrete May 16th.	June 7th
Camp 3—Commenced to pour concrete May 17th.	June 7th
Contract 33 Aqueduct Construction	
Camp 4—Commenced to pour concrete May 19th.	July 12th
Camp 5—Commenced to pour concrete May 25th.	July 7th
Contract 34 Aqueduct Construction	
Camp 6—Commenced to pour concrete May 20th.	July 6th
Camp 7—Has not yet commenced to pour concrete.	
Camp 8—Commenced to pour concrete May 17th.	
Contract 54 Cement	
6,580 barrels of cement were supplied during the month, making a total of 8,460 barrels for 1916.	
Head Office Staff	
Was engaged in preparation of detail plans and in general routine work.	

The work is in charge of the Greater Winnipeg Water District Commission. When completed, pure water will be supplied to Winnipeg, St. Boniface, Fort Garry, East Kildonan, West Kildonan, St. Vital, and Assiniboia. The general manager and engineer in charge is Mr. W. G. Chace. The consulting engineer is Mr. Fuertes, of New York.

Fine New School for Sarnia

CONTRACTS have just been closed by the Sarnia School Board for a modern eleven roomed Public School, to be erected in that city, plans of which were prepared by S. B. Coon & Son, School Architects, Toronto.

The various floors of the building will be utilized as follows:—Ground floor—industrial training and domestic science departments, playrooms, lavatories finished in marble and equipped with sanitary fixtures, heating and ventilating chambers and storerooms. First floor—4 standard class rooms, kindergarten, 34 ft. x 42 ft., with solarium bay, teachers' and principal's rooms. Second floor—six standard class rooms and library.

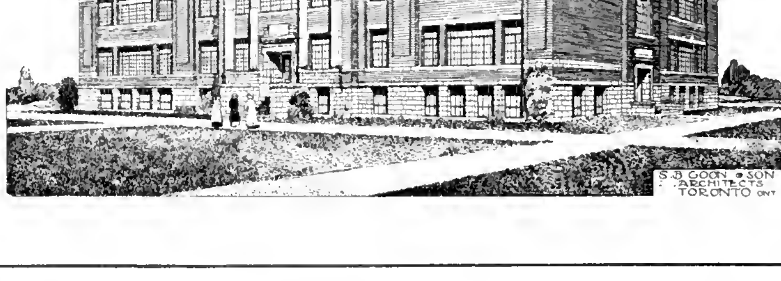
The class rooms will be finished with hard wood floors, slate blackboards, modern seating, and will have spacious cloak rooms in connection with each. An assembly is arranged for by means of sliding partitions between the kindergarten and rotunda.

The exterior will be of red brick, with cut stone foundation and trimmings. The general construction will be semi-fireproof, with steel stairs, terrazzo floors on ground, first, and second floors. Steel casement sash will be used throughout.

Low pressure, automatically-controlled steam heating and electric fan ventilation will be installed. The school is planned for future extension when desired. Schultz Bros., Brantford, are the general contractors.

A test of the flat slab construction of the new Simpson Building, Mutual Street, Toronto, will be conducted by Professor Gillespie, of the University of Toronto, and Mr. W. W. Pearse, city architect, with the object of determining accurately the stresses in the concrete and the reinforcing. A similar test is also planned for the new T. Eaton Company warehouse. The Simpson building was designed by Chicago engineers, while the Eaton one was planned by Philadelphia engineers, and the designs are carried out according to the by-laws of the respective cities. The tests will, therefore, provide interesting comparative results.

Owing to the rapid increase in their business, the John V. Gray Construction Co., Ltd., have removed from No. 348 to No. 625 Confederation Life Building, Toronto, where they will have larger quarters.



Brick Pavements—The Material and Methods Used in Their Construction

By H. E. Breed*

SO much has been written about brick pavements, the building, the selection of material, and the methods used in their construction, that most of you are doubtless thoroughly familiar with the subject from a theoretical as well as practical standpoint. I feel safe in saying that, with the exception of a few minor refinements, very few changes have been contemplated during the past two years. Appreciating your familiarity with these conditions, I thought it might be most profitable to tell of the work that I know best along that line; that is, the practices and methods of constructing brick pavements in the State of New York; such methods as need extra precaution and care; some of the difficulties encountered in sampling and testing; new departures in the form of construction; the number of miles constructed; the average cost per mile; and, in so far as can be given, some data concerning the relative maintenance cost, not exactly of the pavement proper, but of the highway as a whole.

Practices and Methods

It is not my intention to cover all the features of construction. Instead, I should like to emphasize a few of the features often overlooked or only perfunctorily considered, which the work of our department has proven to be of fundamental significance in the success of brick pavements. Other features of equal importance I omit because they have received so much general attention.

In the finished pavement the greatest objection seems to be the longitudinal cracks which appear after the pavement has been down some time. These appear more often on the highways in the country districts than they do in the city streets where there are curbs, sidewalks, and cut-off drains on both sides of the road. This would indicate that on the country highways the cracking comes mostly from a wet subgrade in which there is a certain amount of seepage from the ditches and is due in the main to subsequent frost action; while in the cities where the whole roadway has a protective covering there cannot be quite so large an amount of seepage and therefore we find fewer cracks.

To this end, I should like to emphasize the necessity of adequately draining the subgrade. If we are to build a type of pavement as expensive as brick, the small additional expense needed for drainage is amply justified in comparison with the large initial cost.

It is the opinion of the writer that a sand cushion should not be greater in depth than one inch. This means that the foundation must be uniformly smooth, with the sand cushion acting merely as an evener of the surface. It has been claimed that the sand cushion prevents the crushing of the brick and gives an amount of resiliency that is necessary to a pavement of this type. This statement, however, is not borne out in practice, for I have observed a five-year-old pavement in which a mortar cushion was used that has been bettered by the lack of so-called resiliency.

Another point to which it has been necessary to give very careful attention is the washing of the brick. Many times brick are stored in piles along the road so long in advance of the construction work that they are so spattered with mud from passing traffic and so covered with dust that it is doubtful whether the grout will properly adhere to them. In all cases of this kind I strongly urge that the brick be thoroughly washed so that the grout will have an opportunity to perform its full function in cementing them together. It is well known that if the grout does not perform this function the individual bricks become loose and the sand cushion shifts on the absorption of moisture so that in a short time it is badly in need of repairs. A large percentage of the bad results which we discover in our maintenance work is due to the fact that the grouting did not perform its full function and cement the brick firmly together.

The smoothness of the finished pavement depends largely on the smoothness of the foundation. A little extra care in this respect will amply repay any contractor. Longitudinal expansion joints should be in place before the brick are laid. Good transverse alignment is essential. It is pleasing to the aesthetic sense; it gives workmanlike look to the job, and the curves are more easily worked out if the courses are straight. Every few courses should be straightened by lightly driving the rows to place with a sledge on a 3 by 4-in. timber, 3 ft. long, laid in front of the brick.

Bats less than 3 inches should not be used. If necessary, trim the second brick to accomplish this. The bats should be obtained from bricks culled from the pavement, and as every brick is worth from 3 to 4 cents, in the pavement, the selection of bats should be made from culls so that the good half can be saved. This is an element of fairness to the manufacturers which all engineers will appreciate.

Never roll a brick pavement on a wet cushion.

In order to properly grout a brick pavement, the bricks should be thoroughly sprinkled first. Great care should be given to the thorough mixing of the grout (sand, cement and water) first dry, then to a plastic consistency, and gradually thin out until the mixture just reaches the consistency which will flow. In this manner we are assured of getting the best results. Grout should be applied as soon as mixed, and from mixing to application should be constantly agitated to avoid segregation. Two applications of grout are necessary. The first should merely fill the joints, and the surplus should be swept in with rattan brooms. Just as soon as the first grout has settled and before the initial set can take place, a second application, of slightly thicker grout, should be spread, which should be squeegeed as soon as it is slightly settled, working the squeegee over the bricks at an angle with the joints and leaving them filled flush. In our work we are allowing the contractor to use one part of cement to two parts of sand where they use some form of grout machine. Where they mix by hand in boxes we require them to furnish grout with one part of cement to one part of sand.

Sand

Many bad results in brick pavements can be directly attributed to the use of poor sands. The inconsistency of present day practice is shown by testing the cement and brick both with a fine degree of engineering precision, and trusting the other material, sand, to visual guesswork.

Three different and distinct kinds of sand are used in brick pavements; concrete sand, cushion sand, and

* First Deputy Commissioner, New York State Commissioner of Highways

grout sand. Concrete sand should be clean and have at least 80 per cent. of the strength of Ottawa sand in compression. Its gradation should be as follows:—

Passing the ¼-in.	100 per cent.
Passing the No. 6	85 per cent.
Passing the No. 20	60 per cent.
Passing the No. 50	25 per cent.

and a variation of not over 5 per cent. from these figures should be allowed. Sand with over 8 per cent. of loam should be rejected. This may seem to be rigid specifications, but if a foundation is to serve its purpose it should be strong enough to sustain the pavement with the minimum amount of cracking.

Cushion sand should be of such a nature that 100 per cent. will pass a No. 6 screen and it should not contain more than 20 per cent. of loam.

Grout sand should be clean and of such a nature that it shall have not more than

100 per cent. passing a No. 6
85 per cent. passing a No. 20
30 per cent. passing a No. 50
5 per cent. passing a No. 100

and it shall be rejected if it contains more than 5 per cent. of loam.

Difficulties Encountered in Sampling and Testing

Many of the shale blocks being used to-day show great differences in color produced by different grades of burning. Sometimes there are as many as four or five different shades. In sampling, the department has found that this fact, properly considered, is a valuable aid for the determination in the laboratory of what block may be rejected, and for the information of the inspector in the field when the final culling in the pavement takes place; especially so because there is an observable relation between the shades of color produced by burning and the results of the rattler test. We have, therefore, instructed our men to choose samples according to the different colors and textures and to keep duplicate samples of the same shade and texture to be a good guide to the selection and rejection of the poor brick when the results are determined from the laboratory tests, for any person thoroughly familiar with a given brand of brick and the results of the rattler test on the different shades will be able to cull accurately by visual inspection. This does not apply to all classes of block, for many of them are practically of a uniform range of color. But I know of a number of cases in which it has been of very valuable aid in enabling us to get results procurable in no other way.

It has been suggested at various times, both by manufacturers and by some engineers, that it might be advisable to test brick at the plant. The writer has given this subject careful consideration, and it seems to him that the present practice of sampling and testing brick in the field insures better results than testing at the plant, for the following reasons:—

Brick are not manufactured uniformly in the same sense that cement or asphalts are manufactured as uniform products.

Long experience with a given brand of brick is necessary before they can be accurately culled by visual inspection.

The men best fitted to cull brick by visual inspection are the employees of the brick company.

The sampling from the different benches of the kiln to show the variations in burning can be done more accurately by the burner than by an inspector.

Variations in temperature in different parts of the kiln give different qualities of brick. These can be assorted and selected best by the men who burn them.

Factory inspection of brick places the responsibility of uniform shipments of acceptable brick on the inspector, and offers an opportunity to the brick company to dispose of cull brick because of their lack of responsibility in the selection.

During the last year this department tested 269 lots of brick, comprising 22 different brands and representing a total of 27,000,000 brick. Of these 13.6 per cent. failed to meet the specifications and were rejected. This does no include the amount culled by the inspectors and rejected on the work; which, in some cases, is rather large. With brick tested at the plant, it seems to the writer, that our chances for getting good material would decrease, for if the manufacturers were willing to take such a long chance with a large outlay of freight and handling involved, they would certainly be willing to give inferior material at the plant and would load some brick from the kiln which would not be good enough to go into the work.

New Departure in the Form of Construction

During the past few years two types of new construction have been advocated; one known as the monolithic form, in which the brick are made an integral part of the foundation, and the other the mortar cushion type. Both these have many advantages according to the claims of their advocates. It is the intention of our department this year to try some brick laid with the mortar cushion, and it is our intention in building this type to use some 3-in. and some 3½-in. brick in order to gain economy in the saving of freight charges and handling. It has the advantage of closely approaching the monolithic form of construction, and in that way gives added strength to the pavement. Another advantage is that there can be no failures from swelling or shrinking of cushion sand, and should the pavement crack, only the crack will be affected, and not the whole structure, as is the case when a sand cushion is used.

Number of Miles Constructed and Average Cost Per Mile

Up to January 1, 1916, New York State had completed 238 miles of brick pavements. These different pavements are of varying age and I will later tell briefly of the cost of maintaining them.

The average cost for brick pavement on 5-in. concrete foundation is per mile of 16 to 26-ft. highway, $25,750. The average cost per square yard of pavement only is $2.015. These figures were obtained from an average of 23 highways.

In order to get a comprehensive cost of other types in New York State, I will give figures on water bound macadam, bituminous maradam, and cement concrete.

Water bound macadam:—

Cost per mile of 16-26-ft. highway $10,250
Cost per sq. yd. of pavement only 0.648

The cost per square yard was obtained from 434 values and the cost per mile from 419 values.

Bituminous macadam:—

Cost per mile of 16-26-ft. highway $12,970
Cost per sq. yd. of pavement only 0.871

Both of these items were obtained from the average of 134 highways.

Cement concrete, 6 in. thick:—

Cost per mile of 16-20-ft. highway $15,320
Cost per sq. yd. of pavement only 1.121

Both of these items were obtained from an average of 20 highways.

It will be noted that the difference between the pavement cost and the total cost of the highway lies, in all cases except brick, between $4,000 and $5,000. The reason why the cost of items other than pavement is apparently high on brick roads lies in the fact that the cost of edging has been excluded from the pavement cost, and included in the total cost.

It may be interesting to note that up to January 1, 1915, there had been built in the State of New York 5,167.19 miles of all kinds of highways; during 1915 this department built 1,083.35 miles, making a total of 6,250.54 miles of road. At the present time there are 783.05 miles under contract, which are not completed.

Relative Maintenance Cost of the Whole Roadway

The maintenance charge for 238 miles of brick for the year 1915 was $41,840, or approximately $176 per mile per year. This amount was increased to a large extent by a number of our older pavements which had many replacements. If we eliminate those we find that we would have 107.91 miles of brick pavement which cost $14,185 to maintain and repair. This is at a cost of approximately $131 per mile. These figures, as we mentioned at first, are not the figures from the pavement alone and they include such treatment as cleaning ditches, cost of patrol where patrol was needed, fixing the shoulders which are cut up by the turning out of traffic, the cleaning of slides and maintaining of guard rail. From observation I think it would be safe to say that about 30 per cent. to 40 per cent. of this cost is the average cost that would cover the maintenance of the pavement alone, although in some cases for a series of years, there is practically no cost to the pavement proper.

With these figures it may be interesting to note the cost of maintenance of other types of pavement during the same year computed on the same basis as that for the brick roads, i.e., including the maintenance of guard rail, shoulders, ditches, patrol, etc., as well as the surfacing.

For gravel we find that is cost $577 per mile for 192 miles of road; for water bound macadam we find that it cost $564 per mile for 2,298 miles of road; for penetration method bituminous macadam we find that it cost $448 per mile for 2,387 miles of road; for bitmuinous macadam, mixed method, it cost $181 per mile for 63 miles of road. For second class concrete roads requiring surface treatment it cost $532 per mile for 295 miles of road; for cement concrete pavement, 1:1½:3 mix, it cost $129 per mile for 84 miles of road.

The best results are obtained in brick pavements as in all other engineering works, by strict adherence to details of workmanship and rigid inspection, for in any engineering work or any work of importance and of a contractural nature, inspection is necessary, for it is human nature to get as much out of any situation as is possible. Where contractors are perfectly honest and put all the materials called for in the work, doing it to the best of their ability, it often fails or gives results not commensurate with its cost. This is probably shown to greater extent in highway construction on account of the many new and different types of construction of which often none of the men on the ground have much knowledge. Rigid inspection should be given all construction work and one man at least on every piece of work should have adequate knowledge of the type of pavement to be constructed. He should be selected by virtue of his knowledge of this type and general constructural work, always keeping in mind the personal equation of the man under consideration, his ability to carry out and complete the work in hand. Where inspectors of this kind are not to be had, they should be trained and only those who are proficient and do good work should be kept in this capacity, for the ultimate result is mainly dependent on them.

In conclusion, it is the opinion of the writer that while many good brick pavements have been built, there is still room for improvement in this branch of engineering work and in reaching out for any betterments that are possible, it is hoped that some of the suggestions in this paper will be of help in future work.

Canadian Manufacturers' New President

Thomas Cantley (Hon.-Col.), the president for the coming year of the Canadian Manufacturers' Association, is the president and general manager of the Nova Scotia Steel and Coal Company, and well known the world over for his activities in connection with the iron and steel industries. Like many another prominent figure of modern times, he started business life as a telegraph operator, with the Intercolonial Coal Company. In 1885 he was appointed general sales

Hon.-Col. Thomas Cantley.

agent of the Nova Scotia Steel Company, and has risen rapidly through the various offices of secretary, assistant manager, joint manager, member of board of directors, and general manager (1901), second vice-president (1909), president and general manager (1915). He has travelled widely on this and the European continent, making a close study of the steel industry, which has resulted in the works at Sydney and New Glasgow being among the most efficient and modern in the world. Col. Cantley was born in New Glasgow in 1857.

The summaries of trade imports and exports for the twelve months ending March 31, 1916, just issued by the Dominion Government, are extremely gratifying compared with those of 1915. Imports for that year were $587,304,363, and in 1916, $542,043,563. Exports for 1915 totalled $490,808,877, while in 1916 they increased to $882,872,502.

In the Public Eye

A budget of comment presented in the interest of public welfare, independent of party politics and with malice toward no one.

ROSS RIFLE AGAIN

Startling indeed in view of the attitude adopted by the official and unofficial apologists of the Ross rifle is the news contained in the London letter to the Toronto Telegram. Briefly, the correspondence is to the effect that following complaints from all branches of the service, Gen. Alderson, in command of the Canadians, formally protested to the Canadian Government against arming the men with the Ross rifle, which has proved, according to the soldiers, a failure and a pathetic failure at Ypres and was later to be followed by a similar failure at St. Eloi.

General Alderson's protest was received and answered in a style that unfortunately for the good name of the Dominion is becoming to be regarded as characteristic of the administration of the militia department. He was told to mind his own business and the Canadian soldiers were told to take what the militia department considered good for them and were warned that any further objections to the use of the Ross rifle would not be tolerated. The printed circular containing this warning was apparently an artfully contrived defence of the rifle and an obvious attempt was made therein to blame the faults of the arm on the quality of the ammunition used by the troops.

The main point and the point that will appeal to most people who have little or no knowledge of what constitutes a good military rifle or makes a bad one, is that the men who are using the weapon should be the best judges of its fitness for the work they have to do. When a man's life depends upon the quality of the weapon which is his sole individual defence, he is apt to be curious about it, he is likely to watch its effect and eager to learn all about its dependability, or otherwise, in a crisis. In the case of the Ross rifle there seems to be little doubt that it was unsuitable in the opinion of the vast majority of the men armed with it. That in itself should have been sufficient to cause an investigation of the most careful and painstaking kind. Instead, we are compelled to hear that the protests of the men expressed through their officers and divisional commanders, were received with disdain, and that eventually the Canadians were collectively reprimanded for their attitude and warned that no further nonsense would be tolerated. This to men who were willing and ready to face death for the Empire, and who, it seems to us, should have been given every consideration and whose opinions should have been respectfully listened to and met, if possible. Putting aside all consideration of the technical faults or merits of the rifle, it would seem that it would have been a wise policy to have made a more tactful reply and to have demonstrated to the troops that they were not being sacrificed for political reasons or for any other reason. If the morale of the troops depended on a change f rifle, it should certainly have been effected, and at once. This aspect of the matter would seem to be the common sense view of the dispute.—Ottawa Citizen (Independent Conservative.)

The Toronto Harbor Commissioners have deposited with the Minister of Public Works a description of the site and plans of the bascule bridge proposed to be built across the Don division channel at the foot of Cherry Street.

Personal

Messrs. Smith & Smith have been appointed engineers for Victoria County, Ont.

Mr. A. F. Macallum, former city engineer of Hamilton, Ont., who takes up his duties as commissioner of works in Ottawa, on July 1, was recently presented with a handsome case of pipes and two humidors of tobacco by James Weedon, on behalf of the district and outside foremen, who, at the same time, expressed their disappointment because of his departure.

Mr. J. W. B. Blackman, city engineer of New Westminster, B.C., has been awarded first prize by the Institute of Municipal and County Engineers for an article on the construction of the 25-inch water main and the 13-inch submerged main to Richmond. The Institute has a membership of about 4,000, including practically every city and municipal engineer in Britain and many in the Overseas Dominions. Every year a publication is issued, in which is printed articles from members on matters of professional interest, and the council of the Institute awards three prizes for the three best articles for the year.

Obituary

Lieut.-Col. F. A. Creighton's name appears among the list of those recently fallen in France. Col. Creighton was formerly city engineer of Prince Rupert, Sask., but later has had his head office in Winnipeg, where he carried on a consulting engineering business. Some little time ago he was awarded the Legion of Honor for conspicuous work at the front.

S. H. Reynolds, chairman of the Greater Winnipeg Water Commission, died at the home of his cousin in Chicago on June 16. Mr. Reynolds' early home was in St. Catharines, Ont., of which city he was at one time city engineer. Later, for a number of years, he was assistant to City Engineer, Col. Ruttan, of the city of Winnipeg, but resigned in 1907 to follow the practice of consulting mining engineering in Vancouver, B.C. In 1913 he was appointed chairman of the Greater Winnipeg Water Commission, since which time he has devoted himself entirely to this work.

Col. H. J. Bowman, county clerk of Waterloo, Ont., and senior member of the well known consulting firm of Bowman & Connor, died recently in the hospital in Berlin. Col. Bowman took a very active interest in engineering and military affairs. He was a graduate in 1885, of the Toronto S. P. S., at which time there were only five members in the graduating class. He was formerly town engineer of Berlin, and since 1898 has been a member of the local Water Commission, in addition to vigorously following his profession in the construction of roads, bridges, waterworks plants, etc.

Lieut. H. J. Haffner, formerly the senior member of the firm of Messrs. Haffner & Wartell, civil engineers, Victoria, has been killed in action. Lieut. Haffner was in charge of the machine gun section of the 48th Battalion, which left Victoria last June, but on account of his expert engineering knowledge, he was transferred to the corps of engineers on reaching England. He was a native of Elora, Ont., but had lived in British Columbia for several years prior to the outbreak of the war, having followed the profession of civil engineer during most of that time, and in that capacity he was engaged in the construction of the famous Windermere Road. He was 35 years of age.

Building operations in Quebec, P.Q., continue quite brisk. Building permits to the amount of $144,410 were issued one week recently, one of them, for $55,000, covering an additional storey and repairs to the Commercial Academy on Cook Street.

Mainly Constructional

East and West—From Coast to Coast

The aldermen of the city of Hamilton, Ont., favor the insertion of fair wage clauses in all city contracts.

The Toronto Painters' & Decorators' Association has been incorporated, with head office at Toronto, the provisional directors being Charles Caplan, Louis Bloom, Abraham Price, David Langer, and Mendel Pullen.

The Packard Electric Company, St. Catharines, Ont., are erecting a factory addition, 50 ft. by 145 ft., two storeys high, steel or reinforced concrete construction, brick curtain walls, plank floors, felt and gravel roof. A. E. Nicholson, St. Catharines, is the architect.

The Standard Steel Construction Co., of Port Robinson, Ont., has leased the factory occupied by Dominion Canners and will use this building as an addition to its plant. The new building will be re-equipped and in operation by September, when 200 additional hands will be employed.

Representatives of several municipalities in the Ottawa Valley, in that section between Ottawa and Petawawa, are urging the construction of a trunk road between these two points, and a committee has been appointed to take up the matter of an Ottawa Valley organization for the promotion of the scheme.

The Foundation Co., Ltd., Montreal, have been awarded two contracts by the Algoma Steel Corporation, Soult Ste. Marie, Ont. One is for the revision of the Corporation's yard, the work including the engineering and construction of three through plate girder bridges. The other contract is for the construction of the foundations of two open hearth furnaces, and gas producer plant.

The Electric Reduction Company, Buckingham, P.Q., have let a contract to the Foundation Co., Ltd., Montreal, for a large phosphate plant, on a site 120 x 90. The foundations and floors will be of reinforced concrete, and the superstructure of steel and brick, with asbestos protected metal siding and roof, the latter supplied by the Canadian Asbestos Co., of Montreal. The Dominion Bridge Co. will supply the steel. The engineer is Mr. J. B. McRae, of Ottawa.

At a conference recently with the York County Council, Mr. Geo. H. Gooderham, M.P.P., chairman of the Toronto-Hamilton Highway Commission, asked that a sub-committee of the council be appointed to confer with a committee of the Peel County Council and the Highways Commission, in regard to the reconstruction of the bridge over Etobicoke River. Mr. Gooderham stated that the bridge was too light for the traffic and should be replaced with a stronger structure.

A large caisson, built in connection with the bridge at Moncton, N.B., was recently floated out into the river and moored at the desired point, but the following day it was carried adrift down stream to a point about 400 or 500 feet below the bridge. The contractors hope to save the caisson and will endeavor to raise it when the present high tides fall off. Its cost was about $12,000 or $15,000, and it weighed about 400 tons, having a base of 18 inches of concrete.

September 26th is the date set for the linking of the two arms of the Quebec Bridge, connecting the north and south shores of the St. Lawrence. The huge centre span, weighing 7,000 tons, and measuring 640 feet, will be towed to its position under the bridge, hoisted 110 feet and riveted into position. Captain Haakon Kjerland, Superintendent of the Quebec Salvage and Wrecking Co., will be in charge of this important work, for which the time allowed will only be one hour on account of the heavy tide current.

According to a statement made by Mr. Workman, the president of the Dominion Steel Corporation, at the annual meeting of the shareholders, held recently, it is the intention of the firm to make a number of improvements to their steel plant, the policy being to secure the utmost efficiency and thus reduce costs. The first steps along these lines have already been made in the remodelling of two of the older blast furnaces on the most approved modern lines.

The County Commissioners have asked permission to build a new bridge over the Humber River at Bloor Street, Toronto, at an estimated cost of $25,000, to replace the bridge which was carried away by the spring freshet. The bridge needed will have to span 210 feet and stand up against a very strong current, as well as ice. The county council have decided to inspect the site and get an idea of the form of construction best suited. A temporary bridge, which was erected at a cost of $700, is at present in use.

At a recent meeting of the Ontario Society of Domestic, Sanitary, and Heating Engineers, held in London, Ont., Frank R. Maxwell, of Toronto, was elected president; Fred H. Gentle, of Toronto, was chosen vice-president, and Thomas H. Maxwell, also of Toronto, treasurer. The secretary, G. F. Frankland, of Toronto, was re-elected to that office. The engineers decided that a standardization of plumbing was required, and passed a resolution that the matter be pressed further and that the Provincial Health Board be asked to deal with it at an early date.

Plans for the new Customs House and examining warehouse, to be erected in Toronto, have been recently received in the city. The new building, which will be erected on the site of the present Customs House, and which will be of fireproof construction, will be seven storeys high and will face on Front Street, covering an acre of ground. It will be of grey granite, finished with grey sandstone or Tyndall limestone. Seventeen three-quarter Doric columns, seven feet in diameter and 67 feet in height from the base to the top of the cap, will adorn the front, and three more may be added if the building is extended westward later.

Building and construction work at Sarnia, Ont., now pending approval by the various municipal departments, include, the erection of a new $60,000 school on Lochiel Street, the construction of new sewers, the grading of East Street and Davis Street, the construction of a sewer outlet for six acres of land in Sarnia Township, the improvement of the Fourth Line drain by the installation of 36-inch and 4-foot tile at a cost of about $23,669. The Council granted the request of the Fire and Water Committee to have three cement wells sunk at the lake shore near the 18th and 19th infiltration basins at the new waterworks. The cost of this work is estimated at $5,000.

Trade Publication

Water screens -Folder No. 64, by the Chain Belt Co., Milwaukee, describing their travelling water screens. These are designed primarily to remove refuse and foreign material from water before it enters power plants, steel mills, or any other industrial plant requiring large quantities of clean water.

Accelerating the Hardening of Concrete

Experiments made by the United States Bureau of Standards appear to show that 4 per cent. of calcium chloride added to the mixing water increases the strength of concrete at the age of one day 100 per cent. or more. In some cases the strength of the concrete, in which calcium chloride was used, at the age of two days represented an increase of 75 per cent. or more on the strength normally attained in one month.

Tenders and For Sale Department

Tenders Wanted

Sealed tenders will be received up to noon on **Monday, July 10th, 1916**, for the construction of a Municipal Drain in the Township of Minto, known as Municipal Drain No. 7, approximately 12,411 feet long.

Plans, profiles and specifications can be seen at the office of C. D. Bowman, O.L.S., West Montrose, or at the office of the undersigned, to whom the tenders must be addressed.

A marked cheque for the sum of $150 must accompany each tender as a guarantee of good faith. The lowest or any tender not necessarily accepted.

W. D. McLELLAN,
Clerk of Minto,
Harriston, Ont.

Harriston, June 19th, 1916. 25-27

Tenders for Fire Alarm Signal Boxes

Tenders, addressed to the undersigned, will be received, by registered post only, up to noon on **Tuesday, July 4, 1916**, for the supplying of the above.

Sample of the box can be seen and forms of tender obtained upon application at the office of the Fire Department, Adelaide Street Fire Hall, Toronto. The usual conditions relative to tendering as prescribed by city by-law must be strictly complied with or the tender will not be entertained. The lowest or any tender not necessarily accepted.

T. L. CHURCH (Mayor),
Chairman Board of Control.
26-26

CANADIAN GOVERNMENT RAILWAYS

TENDERS

Sealed tenders, addressed to J. W. Pugsley, Secretary, Department of Railways & Canals, Ottawa, Ont., and marked on the outside "Tender for Elevator Foundations, Transcona," will be received up to and including twelve o'clock noon, **Tuesday, July the 4th, 1916**, for the construction of reinforced concrete foundations on wood piles or concrete piles, for 1,000,000 bushel storage capacity Grain Elevator. Working House and Track Shed at Transcona, Manitoba; separate tenders to be submitted for the foundations with concrete piles and foundations with wooden piles, and tenders may be submitted on either or both designs.

Plans, specifications and blank form of contract may be seen at the office of the Chief Engineer of the Department of Railways & Canals, Ottawa; at the office of the Chief Engineer, Moncton, N.B.; at the office of the General Superintendent, Winnipeg, Manitoba; at the office of the Resident Engineer, Fort William, Ont.; and at the office of the J. S. Metcalf Company, Limited, Engineers, Montreal, P.Q.

All the conditions of the Specifications and contract form must be complied with.

Tenders must be put in on the blank form of tender, which may be obtained from any of the offices at which plans are on exhibition. Each tender must be accompanied by a certified bank cheque, payable to the Honorable the Minister of Railways & Canals, for the sum of $15,000.

The lowest of any tender not necessarily accepted.

F. P. GUTELIUS,
General Manager
Canadian Government Railways.

Dated at Moncton, N. B.,
June 17th, 1916. 25-26

Sealed tenders addressed to the undersigned, and endorsed "Tender for stone stairway, sidewalks, etc., Examining Warehouse, Ottawa, Ont.," will be received at this office until 4.00 P.M., on **Wednesday, July 5, 1916**, for the above mentioned works.

Plans, specifications and form of contract can be seen and forms of tender obtained on application to this Department, at the offices of Messrs. Thos. Hastings, Clerk of Works, Postal Station "F," Yonge St., Toronto, Ont., and R. L. Deschamps, Overseer, Central Post Office, Montreal, P.Q.

Persons tendering are notified that tenders will not be considered unless made on the forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering declines to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, June 21, 1916.

Newspapers will not be paid for this advertisement if they insert it without authority from the Department.—86827 26-26

Tenders Wanted

Separate sealed tenders addressed to S. K. Peck, Esq., Chairman, Water Commissioners, Windsor, Ontario, and marked "Tender," will be received by the undersigned up to 12.00 o'clock noon, on **Thursday, July 6, 1916**, for:—

(a) 10 tons, more or less, of specials, consisting of crosses, tees and reducers.

All according to standard specifications and adopted by Canadian Society of Civil Engineers, Class C.

(b) 6 in., 8 in., and 12 in. valves; spindles to be of Manganese bronze, open to right.

(c) 20 tons of pig lead.

(d) 35 hydrants, to bury 5 feet, having 6-in. barrel, with 2-2½-in. and 1-4-in. steamer connection.

(e) 24 extension valve boxes, 5 ft. in length.

(f) 1,000 lbs. of hemp.

All the above to be delivered f.o.b. cars, Windsor, Ont.

A certified cheque payable to the order of the Water Commissioners, equal to 5 per cent. of the amount of each section of above tenders, must accompany each tender, which cheque in case of an unsuccessful tenderer, will be forthwith returned, but in the case of the successful tenderer, will be retained until a satisfactory bond for the due performance of the work is executed, or if the successful tenderer for any reason neglects or refuses to execute a satisfactory bond within 15 days after notice that his tender has been accepted by the Water Commissioners, said cheque will be cashed, and the expense of re-advertising the work required and any additional cost in connection with the same over the amount of his tender will be retained from the proceeds of such cheque.

The right is reserved to reject any or all tenders; or to accept any tender.

The Water Commissioners
W. A. HANRAHAN, Secretary.

June 24th, 1916. 26-26

Sealed tenders, addressed to the undersigned, and endorsed "Tender for Examining Warehouse, Toronto, Ont.," will be received at this office until 4 p.m. on **Monday, July 17, 1916**, for the construction of the building mentioned.

Plans, specification and form of contract can be seen and forms of tender obtained at the office of Mr. Thos. A. Hastings, Clerk of Works, Postal Station "F," Yonge Street, Toronto, Ont., Mr. R. L. Deschamps, Central Post Office, Montreal, P. Q., and at this Department.

Persons tendering are notified that tenders will not be considered unless made on the forms supplied, and signed with their actual signatures, stating their occupations and places of residence. In the case of firms, the actual signature, the nature of the occupation, and place of residence of each member of the firm must be given.

Each tender must be accompanied by an accepted cheque on a chartered bank, payable to the order of the Honourable the Minister of Public Works, equal to ten per cent. (10 p.c.) of the amount of the tender, which will be forfeited if the person tendering decline to enter into a contract when called upon to do so, or fail to complete the work contracted for. If the tender be not accepted the cheque will be returned.

The Department does not bind itself to accept the lowest or any tender.

By order,
R. C. DESROCHERS,
Secretary.

Department of Public Works,
Ottawa, June 16, 1916.

By slipping 24-in. wide butt-welded tires of ½-in. thick steel over the regular wheels of a paving mixer, made by the Chain Belt Company, a contractor for road construction in Glenwood, Iowa, converted the mixer into a road roller at a cost of $75. The outer half of each new tire was filled with 1 to 2 mixture of sand and cement. Samuel Friedman, the contractor, states that the converted mixer rolled the subgrade with very satisfactory results, although there were several backfilled trenches in the road. Owing to the fact that shipments of coarse aggregate for the concrete were delayed on this work, it was possible to roll the entire subgrade without using a regular roller on the job.

Bagotville, Que.
The J. G. White Engineering Company, New York, have started work on the construction of a paper pulp mill for the Ha Ha Baie Sulphite Company, Chicoutimi.

Blair, Ont.
Work has been started on the erection of stables for Miss Wilks. The contract for cement work has been let to George Haller, Preston, and for steel frame to the Metal Shingle & Siding Company, Preston. Approximate cost, $6,000.
